THE MAJOR OBSTETRICAL OPERATIONS.

FROM THE STANDPOINT OF THE GENERAL PRACTITIONER WITH A TABULAR REPORT OF TWENTY-THREE CONSECUTIVE SUCCESSFUL CASES.*

EDWARD REYNOLDS, M.D.
BOSTON.

GENERAL PRINCIPLES.

The recent advances in the study of the contracted pelvis, and the possibility of saving fetal life in such cases, by the extension of the major operations to a wider field, have as yet been confined too exclusively to the practice of professed obstetricians, and too little popularized among the great mass of the profession; perhaps because it has been thought by many that the technicalities involved in the detection of contraction are too great for the general practitioner's use, and probably because there is still too much credence for the former erroneous idea of the comparative scarcity of contraction in America. This belief must, however, be given up. The results of all those who have recently investigated the subject having yielded about the same percentages of contraction, namely, about 11 per cent., if we except the negroes, in whom it rises to nearly 20 per cent. Only about 2 per cent., however, reach the degree of mechanical obstruction which demands operation; but when we consider that in each of these cases the question of whether the woman shall be delivered by one of the ordinary methods or by a cutting operation, must necessarily be raised, even this percentage is surely large enough to make the question one of living importance to every general practitioner.

The operations to be considered in any such cases are forceps and version, the induction of premature labor, craniotomy, the Cesarean section with or without the extirpation of the uterus, and symphysiotomy. The choice between them must always be determined by a consideration of their respective maternal and fetal mortality, under the conditions of the individual case. The short time allotted makes it impossible for me to discuss in detail both the status of all these operations and their application to practice, and as I have recently published[1] a detailed paper on the status of the cutting operations, I propose to limit myself here to a bare statement of the mortalities, unsupported by argument, in order to afford myself room for a full discussion of the application of these results to everyday practice.

As an essential preliminary to any intelligent consideration of these mortalities, we should first, and for each operation, subbivide the cases into favorable and unfavorable classes, putting in the favorable class all those in which at the time of operation the woman is uninfected, not exhausted by long labor, and free from complicating diseases; and per contra, into the unfavorable class, all cases in which the woman is already exhausted by neglected labor, infection, or other intercurrent disease.

FORCEPS AND VERSION FOR CONTRACTED PELVIS.

It will, I think, be conceded by any obstetrician of wide experience, that the use of high forceps and version for contracted pelvis has a small *intrinsic maternal* mortality, yet we shall find that this maternal mortality is insignificant or non-existent in the hands of skilful men and when the operations are undertaken with the mother in thoroughly good condition, but that it will not be insignificant in the unfavorable class of cases.

It is generally and somewhat loosely held that the fetal mortality of high forceps and version is not unduly large, but I think any one who will analyze a large series of cases with regard to this point, will be surprised to find how large the fetal mortality is. I have myself found that analyses both of my own experience, and of a considerable number of reported series of cases, have uniformly yielded about the same result, that is, a *fetal mortality of not less than 50 per cent., in cases* in which high forceps or version was performed on account of contracted pelvis. (We must, of course, exclude cases in which these operations are done for less important mechanical obstacles; in which cases the fetal mortality is naturally much smaller.)

INDUCTION OF PREMATURE LABOR FOR CONTRACTED PELVIS.

In these aseptic days the maternal mortality of the induction of labor is and should remain exceedingly small, but in this class of inductions the reported fetal mortality is far from small, being about 50 per cent.;[2] *a statistical* result which is, moreover, supported by the opinion expressed in the more recent text-books.

CRANIOTOMY.

Since craniotomy to the living child is practically never performed until after the failure of determined attempts at extraction by high forceps and version, its maternal mortality is necessarily a little higher than where these operations succeed. Its fetal mortality is, of course, 100 per cent.

THE CLASSICAL CESAREAN SECTION.

Until very recently, it has been generally held that the maternal mortality of the Cesarean section was still not less than 25 per cent., and if all the reported cases are considered together this opinion is probably a true one, but a division of the cases into the favorable and unfavorable classes, defined above, yields surprisingly different results. Thus an analysis which I made a year ago of 150 reported cases, 15 of my own and the remainder from foreign sources, shows that there were 89 cases in the favorable, and 61 in the unfavorable class.[2] Among the 89 favorable cases there was no maternal mortality, while the mortality of the unfavorable cases reached the prohibitive figure of 33.3 per cent.

---

* Read before the Obstetrical Section of the New York State Medical Association.

[1] Obstetrics, January, 1900.

[2] Estimating an unduly prolonged labor at the arbitrary limit of twenty-four hours.

The fetal mortality of the Cesarean section is, of course, the smallest mortality known, amounting to nothing in the favorable class of cases.

PORRO'S OPERATION.

This extirpation of the pregnant uterus has been almost invariably confined to the unfavorable class of cases. There is perhaps not yet enough material for estimating its maternal mortality when done early in labor and in selected cases. It is probably but slightly *greater than that of the uncomplicated section.* Its mortality in the unfavorable cases is somewhat lower than that of the Sänger section, but reaches about 30 per cent. Its fetal mortality is that of the Cesarean section, that is, it is never fatal to a child which is in good condition at the time the operation is undertaken.

SYMPHYSIOTOMY.

When the reported cases of symphysiotomy are separated into the favorable and unfavorable classes, the operation is found to have a somewhat larger maternal mortality than the section in the first set of cases, those in which women were in good condition, the small mortality which exists being due to an occasional improper selection of cases, that is, to the performance of symphysiotomy in pelves of too high a degree of contraction to admit of easy extraction after it had been performed. Its fetal mortality is practically confined to the same mistaken cases; but, though this is a mortality of mistake, the fact that it has been frequently made by men of world-wide reputation makes it necessary to consider it. In contrasting symphysiotomy with the classical Cesarean section in the favorable class of cases, it must, moreover, be remembered that even if it attains an equally low maternal mortality, its morbidity is considerably higher than that of Cesarean section, that is, serious injuries to the soft parts occur not infrequently, and loss of locomotive ability from permanent mobility of the pelvic bones is not unknown. In the unfavorable class of cases, however, the maternal and fetal mortality of symphysiotomy both compare favorably with those of any other operation, and, in my opinion, it here finds its chief indication. It is unattended by shock; it does not open the genital canal, and can therefore be performed in infected cases; it makes the subsequent extraction by forceps or version easy instead of difficult.

CONCLUSIONS.

The conclusions to which I have been forced by my study of the subject, which have since been supported by the results of every reported case that has come under my observation, and which have led me to an unbroken success in dealing with all the major cases that I have seen since I finally formulated them—23 cases in four years—are as follows:

1. When the conditions are such that the child can be delivered with anything like reasonable ease by forceps or version, one of these operations is preferable to any cutting operation.

2. When the mechanical relations would render forceps or version unusually difficult, forcible and prolonged, and when the mother is in the favorable class, the equally low maternal mortality and the far lower fetal mortality of the Cesarean section render it the operation of choice.

3. When the mechanical conditions make the intrapelvic delivery of an intact child at term impossible or unduly difficult, the great superiority of the Cesarean section over the induction of premature labor in fetal mortality, and its extremely low maternal mortality render it again the preferable operation.

4. When the ordinary operations fail and the woman is in the unfavorable class, symphysiotomy is the operation of choice, and may be expected to lead to a favorable result for both mother and child in the great majority of cases, provided always that the degree of mechanical difficulty permits of its application.

5. When in the unfavorable class of cases, the degree of relative disproportion between head and pelvis is too great to admit of a safe symphysiotomy, craniotomy to the living child should be unhesitatingly chosen, since the maternal mortaliy of either form of the section is so enormous, and because I can not doubt that the life of the potential mother of many children is of more value than that of any unborn fetus.

APPLICATION TO PRACTICE.

If these principles be true, it follows that there are but few, if any, cases of uncomplicated mechanical obstruction in which a happy outcome for both mother and child is not easily within the power of ideally prompt and intelligent medical care, if applied at the beginning of labor. I believe this to be a fact and I think that this happy state of affairs is sufficiently possible of accomplishment to encourage us in every effort toward its attainment. The method which is commonly laid down *as a necessity to this end is the routine measurement of every case at the time it first comes under the practitioner's care.* I am far from underestimating the value of routine pelvimetry, and hope to see the day when it will be a part of every obstetric examination, but I believe that there is no use in disguising from ourselves the fact that it is not now, and for the present is not likely to be, generally practiced; if only from the fact that the attainment of an accurate conception of the mechanical possibilities of a given pelvis by mensuration is not an easy matter to any one, and that, moreover, the active general practitioner of to-day has not been educated in it, and can hardly be expected to perfect himself in this particular. The popularization of pelvimetry must be expected from the graduation of students who have been carefully taught it during their course in the medical schools. Valuable as mensuration is, moreover, it is fortunately not essential to the attainment of very fair results in mechanically obstructed labor. Every day of increasing experience makes it more certain that the supreme test of the adaptation between head and pelvis is the test of actual labor, and that the all-important thing is the clinical recognition of a mechanical obstruction early in the course of labor. The variations in the size and hardness of the fetal head are so great that there are, in my opinion, few cases of contracted pelvis in which any one is justified in performing a major operation without applying to the case the supreme test of an actual labor, or the history of past labors; and this clinical test is easily within reach of the general practitioner if he will conceive the case properly. Let us then discuss his duty in the course of his care of pregnancy and labor, from the standpoint of the cruder methods which are possible to everyone.

The importance which attaches to the actual clinical test necessarily places primiparæ and multiparæ in widely different clinical classes, and it is natural to discuss the primiparæ first.

PRIMIPARAE.

I would, then, advise the general practitioner that when a primipara comes under his care during the course of pregnancy, he should always include the possibility of marked mechanical obstacles as among the contingencies to be considered in his mental estimate of the case. If the woman be especially small, if she has a history of early caries, either of the hip or spine, or if any other symptoms point to a possible dystocia, he should take her to an expert for the estimation of the size of the pelvis, in consultation, early in pregnancy, precisely as he would treat any other certain grave surgical complication in his practice. Even if no such threatening symptoms exist, he should, preferably a few weeks before labor, and at all events at his first visit in labor, notice whether or not the head is unusually high. This, though not ideal, is, I think, the best test which we can expect at present to have applied to general practice in the case of primiparæ; it is, moreover, a fairly good one. If the head is, at the beginning of labor, well crowded down into the brim it will very rarely if ever happen that the case is beyond a possible delivery by forceps, and if such a delivery results fatally to the child, the question of choice of operations can be taken up at the next pregnancy. On the other hand, if in a primipara with the rigid abdominal and uterine walls which belong to her condition, the head is at the beginning of labor high above the brim, the question of serious relative disproportion between the head and pelvis is always prominent. The point which must now be remembered is that the chance for a successful Cesarean section is limited to the early part of labor and that the choice must be made then and can not be deferred to a later time. What the practitioner should do in such a case must depend on varying factors, such, for instance, as his methods of practice, his relation to the individual patient, and the locality in which his practice is situated. He may choose between an immediate and careful measurement of the pelvis, externally and internally, himself, if he feels competent for it, or an immediate consultation with an expert, not necessarily on the subject of an immediate delivery, but on the question of whether there is a sufficiency of room; and this consultation will seldom be objected to by the family if it is put before them in this way. If a contraction of the pelvis is found, preparations for a section should be made on the chance that its performance may be necessary. If then the dilatation of the os progresses with fair rapidity and without the appearance of any exhaustion of the patient, nothing is done until toward the termination of the first stage. If the first stage is tedious and exhausting, the patient is etherized while still in good condition and the os gently dilated manually. The hand is then passed into the pelvis, under anesthesia, of course, and made to palpate and measure it with the greatest care; it is next passed up to palpate the head, both to ascertain its size and the relation which its greatest diameter bears to the pelvic brim when it is strongly crowded down into the pelvis by a suprapubic hand. If this test is inconclusive, the forceps are applied to the sides of the head with the greatest care and a few gentle tractions made in order to determine the amount of resistance which is to be expected, and to study the application of the individual head to the individual pelvis by the introduction of the fingers alongside the forceps during the tractions. At the same time the fetal heart is carefully watched to judge of the effect of the tractions on the child. It is manifest that this method of studying the case requires an extended obstetrical experience for a due appreciation of its results, and I believe that in case of doubt the decision should be given in favor of the lesser operation, in primiparæ at all events, since in the present state of our knowledge it is better that we should risk losing one child than perform an unnecessary Cesarean section; but with due care and caution and in sufficiently skilled hands, I believe that this test will yield nearly certain results, and that the doubtful cases will consequently be rare. I believe that the adoption of this simple rule —that an unusually high or inaccessible position of the head at the beginning of labor should be regarded as ground for a consultation—will lead to greatly improved results.

In the present condition of medical practice we can not doubt that the children of primiparæ will occasionally be lost, who might have been saved by an early resort to a cutting operation, and that symphysiotomy will be done in other cases where the preferable Cesarean section might have been selected had the gravity of the case recognized earlier; but when the primipara has become a multipara, the case is much more simple.

MULTIPARAE.

Once the general practitioner realizes what the public is already beginning to know, that the loss of a child in labor from mechanical obstacle is a loss which might probably have been avoided; once he recognizes what will, in my opinion, before many years be recognized by the profession far and wide, that the mortality and morbidity of the major operations done at the beginning of labor are no greater and probably less than those of violent and prolonged forceps extraction, very few children of multiparæ will owe their death to any mechanical cause. The rule which will save them is again a simple one. When a woman has once lost a child in labor from mechanical obstacle, that is, from difficult delivery by forceps or version, the question of a major operation at term should always be taken up during the next pregnancy of that woman, that is, a consultation should be held, at latest a few weeks before delivery. The pelvis will then be measured and the relative size of the pelvis and the individual head will be estimated by the hand. If distinct disproportion already exists, the case may conceivably be treated by Cesarean section at the beginning of labor, or at a date set just before it. In a larger number of cases, the estimation of relative size will be repeated at term and the woman will be allowed to go through the earlier hours of labor, but with every preparation for the performance of a Cesarean section already made, and with an operator at hand, so that in the event of another failure of the powers of nature the favorable moment can be seized and another fetal death in labor avoided.

Is not all this a simple and rational application of our recent advances to ordinary general practice? It may be objected that I have insisted too much on the employment of an expert wherever the question of relative disproportion is a prominent one. I would reply that every great advance works harm by the over-enthusiasm and rashness of the ill-prepared. That the decision in favor of or against a major operation in a given case is, in my opinion, in most cases, a very delicate and difficult one: one which should be submitted to a man with a professed proficiency in the subject. Obstetrics is rapidly reaching a position in which its

best exponents are able to exhibit as definite results as are obtained in other branches of modern surgery, and I believe that the profession will before many years be compelled by the public to feel its obstetrical responsibilities with the same seriousness which has long been accorded to surgery. Once the public and the general practitioner feel that almost every fetal death from mechanical obstacle must be charged to the want of exceptional skill on the part of the attendant, we shall have far fewer deaths in labor. In every large city the men who are ready to consider this question are plentiful, and when cases of the sort occur at a distance from such a center they must be settled by the best man accessible.

I wish finally to repeat my firm belief that in all cases of doubt we should be guided by the general proposition that a manufactory is always of greater value than any single sample of its products, and that the potential mother of many children is always of more value than a single child; though I believe that in well-handled cases the interests of mother and child are to-day almost invariably identical. In illustration of the position which I am supporting I wish to close my paper with a short history of the twelfth case on my list, one which illustrates unusually well that position.

Early in the winter of 1898 and 1899, Dr. O. F. Johnson, of Winthrop, Mass., wrote to me that he had a primiparous patient whose small size had led him to apprehend difficulty in labor, a fear which had been encouraged by the slightly small external measurements which he had taken. He informed me of the calculated date of delivery, and asked that I would make a note of it and come to his assistance prepared for any method of delivery if the early part of labor did not progress satisfactorily. On July 18, 1899, he telephoned me that the patient was in labor, and later in the day telephoned that the progress of labor was not quite satisfactory to him, and asked me to see her. I went at once, prepared with assistants and instruments for any form of delivery, including the Cesarean section. The patient was a primipara, fifteen years married, and a very small woman. She had had moderate labor pains for about eighteen hours, but was in excellent condition, with slow pulse, and not exhausted. The membranes were unruptured, the os about the size of a fifty-cent piece. The pelvis measurements were as follows: Spines of the ilium 21 cm.; iliac crests 26 cm.; external conjugate 18 cm.; diagonal conjugate 9.5 cm. The symphysis was erect, the promontory high, the form of the pelvis justo-minor, and I estimated the true conjugate at not over 8 cm. It was thus decidedly a small pelvis, but on dilating the os, which was done with greatest ease, the patient being under ether, and seizing the child's head with the hand, it was evident that the head was not large, the fontanelles and sutures were wide, the bones were soft, and I was inclined to believe that an intrapelvic delivery was possible. The occiput was anterior, O. L. A. I easily applied the forceps and easily brought the head into the brim, but two strong tractions failed to advance it farther, and on listening to the fetal heart, which had previously been strong and regular, I failed to hear it. The forceps were at once removed, the head pushed back and the hand passed into the uterus in search of the cord, which was found to be beating faintly and intermittently. I felt that even the few tractions which I had made had been too powerful for the soft head and feared that I had lost the child, but after a few minutes spent in watching the cord with the fingers its pulsations became good and regular, having steadily improved during the interval. The hand was then removed, and some minutes spent in watching the fetal heart with the stethoscope. It continued good and strong. The child's condition was evidently re-established, and as the mother's pulse was slow and good, and I was confident I had done no harm to the soft tissues with the forceps, I felt warranted in still considering the Cesarean section. I informed the doctor and the husband that I had no question that I could deliver an intact child by forceps without material danger to the mother, but I was equally sure that the child would be a dead one, and that I thought the Cesarean section could be performed without essentially increasing the risk to the mother. Both of them assenting, my assistants were called up, the necessary preparations rapidly made, and a classical Cesarean section done. The child had passed meconium into the liquor amnii and was somewhat asphyxiated, but was resuscitated without great difficulty and has done thoroughly well ever since. The mother's recovery was uneventful. I criticise myself as having in this case gone a little too far in the use of forceps in so small a pelvis, but I believe if a mistake is made it is better to make it on the side of conservatism, and I hoped to be able to deliver safely with forceps. The case is, with this exception, a fair illustration of what I consider a rational method of deciding between the Cesarean section and the forceps.

TREATMENT OF SESSILE AND CERTAIN OTHER OVARIAN CYSTS.*

H. B. STEHMAN, M.D.
LOS ANGELES, CAL.

Other things being equal, our operative methods should follow lines which involve a minimum of injury to important structures, the greatest preservation of tissue, including the blood, and the least amount of shock possible.

The question at issue is whether in dealing with some of the cysts under consideration we might not obtain the same results with less radical measures, and therefore with less risk to the life of the patient. The object then, of this paper, is to give the clinical results of a method that is simple, applicable in a certain percentage of these cases, and so far as I know not usually employed and to call attention to the success of the same plan in similar pathologic conditions in other organs.

The non-pedicular cysts of the female adnexa as a rule develop either from the ovary—paroöphoron—or the parovarium; for the most part they grow between the layers of the broad ligaments and thus are in intimate relation with the cellular tissue, vessels, ureter and bladder beneath and in front, the muscular and serous coats of the broad ligaments and ovary on the sides, the superimposed tube and peritoneum above.

The parovarian cyst is usually unilocular; when small the walls are exceedingly thin and transparent and the fluid contents limpid and sterile; as the tumor increases in size the epithelial lining undergoes change, the walls become thicker, more dense, and slightly opaque, while the fluid becomes turbid, but usually remains sterile. These cysts develop from the paroöphoron and parovarium as a result of the stimulation due to the advent of puberty (Sutton), and are often mistaken for oöphoron cysts and so treated. As stated, they grow within the mesosalpinx and are thus literally part subperitoneal and part intraligamentous. If the development is upward the tube becomes quite tense, so that its lumen may be occluded and its function destroyed; if downward, it may simply displace the ligamentous structures, lying imbedded in a sac of dense connective tissue, from which it may be readily enucleated, or become intimately associated with these structures and thus be difficult of removal.

---

* Read before the Los Angeles Medical Society, June 1, 1900.

After removal, in the former case we may simply have to deal with a dead space; in the latter a formidable hemorrhage, injured structures and a veritable cavity are the conditions which may either endanger the patient's life or protract convalescence by the defect becoming an infection atrium, or a circumscribed pus sac. In some of these cases, especially those which show signs of malignacy and some multilocular cysts, ligation of the ovarian and uterine vessels previous to enucleation is quite imperative, and in these the obliteration of the undisturbed sac would be impracticable, but in the monocysts and non-malignant growths, even if hemorrhage is controlled by previous ligation, the patient still does not escape the danger of injury to the ureter and bladder, either in the enucleation of the tumor or the obliteration of the sac, and if the latter be impossible it may only be successfully drained per vaginam; in which case, in spite of our best efforts it usually becomes infected before it is completely closed. This infection is protracted because of the dead space that necessarily is formed by the removal of the cyst and which is not effaced by approximation of the broad ligaments; in endeavoring to bring these together the task becomes both difficult and dangerous because the growths, frequently displace and deform the contiguous structures to such a degree that it becomes almost impossible to recognize them by anatomical differentiation.

It seems to me, therefore, that the proposition becomes simpler, if, instead of trying to enucleate these cysts, we should instead, after having carefully evacuated the cyst contents and removed the redundant portions of the wall, destroy the lining by the use of proper escharotics and close the orifice by suture.

The cautery or the curette is sometimes advised in the most difficult cases, but reasoning from analogy the hyperstimulation resulting from chemical irritation would accomplish all that is necessary and yet be attended with less danger. The result of such application is the destruction of the epithelial or other structural layer of the cysts by albuminous coagulation which subsequently liquefies and is absorbed, leaving a sterile dead space, or by connective-tissue proliferation becomes obliterated through adhesive inflammation.

A resultant dead space is not an unnatural termination under the circumstances, for while Nature naturally abhors a cavity, nevertheless we frequently find an unoccupied sterile pleural cavity owing to a collapsed and adherent lung, or spaces of varying size in the soft tissues due primarily to pressure necrosis and subsequent absorption, owing to the presence of some metallic or other foreign substance. In an unusually thick sac, in which fatty degeneration does not occur, it is quite natural to suppose that after dehydration, the tissue would undergo mummification similar to the papyraceous ectopic ovum. There need be no fear in leaving a portion of the sac, since in extensive intestinal adhesions to an ovarian cyst or other neoplasm, if separation of the intestines produces serious trauma, the adherent portion is frequently left without serious results.

In the commonly accepted treatment of hydrocele, glandular and simple unremovable congenital or retention cysts, whether by the aseptic open method or the injection of tincture of iodin, or carbolic acid with the adhesive obliteration of the sac, we have the analogue of the method suggested in dealing with the cysts under discussion.

The disposition of an ovarian cyst, whether pedunculated or sessile, without resorting to the usual manipulation of adjacent organs which is frequently necessary in ligation or enucleation seems of still greater value when coexistent with pregnancy. While gentleness is required in all intra-abdominal manipulations, still, in handling the gravid uterus, we can not be too careful, and yet in spite of the greatest precautions in endeavoring to ligate a pedicle or enucleate a cyst it may become so displaced that in recovering its position, or in becoming adjusted to its environment, forces may be excited that eventually result in premature labor. It seems that here also the obliteration of at least a portion of the sac, in view of the fact that it could be done with less disturbance of the viscera, especially if the blood-vessels were not unusually large, would be the preferable operation. I believe, moreover, that the complication of premature labor which so frequently follows operation in these case, is due not primarily to the operation per se, assuming that there has been no infection, but as has already been suggested, to the readjustment which necessarily takes place in the restoration of the uterus subsequent to the removal of the cyst, whether that readjustment be a return to the position which it previously held and from which it was disturbed by our manipulations, or a new relation in consequence of the removal of a cyst which caused either lateral or upward displacement. In either event it is easy to conceive how a train of forces may be set in motion which sooner or later may result in labor.

In removing the support which especially a pelvic cyst affords, the uterus naturally sinks into the pelvis, just as in normal pregnancy, a short time previous to labor, a fact which I am sure we do not sufficiently appreciate nor guard against by keeping the patient at least partially on her side during and after the operation in case of an abdominal cyst, or in the elevation of the hips and lower extremities under the same circumstances, and maintaining this position, combined with cautious tamponing of the vagina, if from the pelvis. The contention therefore is, that in destroying or obliterating a portion of a cyst, instead of removing it, we are accomplishing all that an operation can accomplish, and that since this can be done in less time, with less violence, and consequently less risk, it should more frequently be the course of election.

The following case, with its varied pathology, will suffice for illustration:

Mrs. A., aged 35; nullipara; presented symptoms showing marked dyscrasia. Examination revealed ascitic fluid, with a fluctuating abdominal tumor. History and symptoms pointed likewise to tubercular peritonitis. At the operation, a central abdominal incision exposed a thickened parietal peritoneum forming the anterior wall of an abscess which filled the greater part of the pelvic cavity, being circumscribed and limited by matted coils of adherent intestines on which were characteristic tubercular deposits.

After emptying the sac, and thorough irrigation, permanent drainage was obtained by passing a T tube through the floor into the vagina, and another tube was secured in the dependent angle of the wound through the abdominal wall, the wound closed and sealed with iodoform collodion and cotton. On either side of the sac a fluctuating tumor could be recognized; that on the left was diagnosed as an ovarian cyst, but the pathology of the one on the right was not so clear.

An incision in the median line above the umbilicus disclosed the same studded tubercular deposit on the intestines, with ascitic fluid, and a left unilocular, ovarian cyst, with a short pedicle, extending to the umbilicus; on the right a pyosalpinx, firmly adherent to the remaining unoccupied portion of the right pelvis, containing about four ounces of pus. It was utterly impossible either to ligate the pedicle of the cyst or remove the pyosalpinx, 1, on account of the height of the incision; 2, because of the immobility of the adherent intestines and the circumscribed abscess sac which occupied the bulk of the pelvic cavity.

After carefully walling off the intestines, the cyst was aspirated and about three-fourths of the collapsed wall removed; the interior of the remainder was thoroughly painted with tincture of iodin and, by the aid of a long dissecting forceps and needle holder, the marginal ends were turned in with an over-and-over continuous stitch. The pyosalpinx was aspirated in the same manner, the sac laid open, as much as could be reached removed, and, after careful sponging, the cavity cauterized with a solution composed of equal parts of carbolic acid and alcohol, care being taken to sponge out an excess of fluid which might remain. After closing the sac in a manner similar to that employed with the cyst, the abdominal wound was sutured and sealed.

Except for the through-and-through irrigation of the pelvic abscess, the convalescence of the patient presented no special points of interest, and the recovery from the lesions of the adnexa was ideal.

The case represents a type of those in which it is very difficult to remove the pathologic lesion, owing either to the location of the tumor or its structural intimacy or relation with some important organ, and furthermore illustrates the feasibility of cyst obliteration where removal is impossible. In the evolution of medicine we are not only developing more exactness, but greater simplicity; instead of prescribing for a disease we quiet a vasomotor disturbance by an agent of known physiologic action. In surgery we are in pursuit of the same ideals, and these are being realized as a result of more accurate anatomic differentiation and by the application of well-established and tried general principles in specialism. And thus, in dealing with the pathology under discussion, with greater experience and more extensive observation, the principle will appeal to us because it is rational, and while, surgically, pedicle ligation and extirpation may seem the more logical, the alternative suggested will be employed more frequently because of its signal advantage, becoming the operation of election, instead of, as now, the one of necessity.

217 South Broadway.

Obligations of Physicians Receiving Salary.—The French courts recently decided against a physician sued for damages by the widow of a pauper, on the ground that he did not respond promptly and made but the slightest examination, although he was the official, salaried physician to the poor of the community. The courts said that a verbal or written contract compels the physician to respond to calls and to continue his attendance in such a manner that no one can accuse him of negligence.

PARALYSIS AGITANS WITHOUT TREMOR.*

AUGUSTUS A. ESHNER, M.D.
Professor of Clinical Medicine in the Philadelphia Polyclinic: Physician to the Philadelphia Hospital; Assistant Physician to the Orthopedic Hospital and Infirmary for Nervous Diseases.
PHILADELPHIA.

It is probable that no system of nomenclature yet devised is capable of meeting all requirements, because of constant additions to knowledge and corresponding variations in classification. This difficulty is especially manifest in medicine, where names are chosen sometimes from fancied resemblances, or from the prominence of certain symptoms or certain lesions, or on the basis of current and varying clinical or pathologic conceptions; or, worst of all, in intended honor of the discoverer or exploiter. With the progress of knowledge and with more extended observation, however, it not rarely happens that symptoms or lesions considered so distinctive as to be incorporated into the name given a disease, are found to be not invariably present, but are at times so ill developed as to be inconspicuous. Thus, we have learned from experience that typhoid fever may be unattended with typhoid symptoms, or elevation of temperature, or intestinal lesions; exophthalmic goiter, without either protrusion of the eye-balls or enlargement of the thyroid gland; scarlet fever or smallpox, without exanthem; paralysis agitans or shaking palsy without tremor or agitation or true palsy.

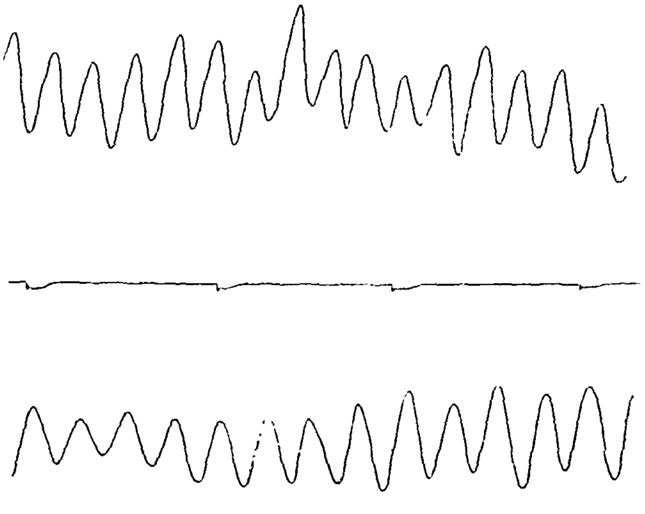

Fig. 1.—Both curves exhibit the inhibiting influence of passive extension of one of the fingers. The interrupted straight lines represent time in seconds. To be read from left to right.

The tremor of paralysis agitans is so distinctive and so constant that one might consider the diagnosis exceedingly difficult if at all possible in its absence. Even then, however, there is something in the *tout ensemble* of the case that makes the recognition comparatively easy and certain, if one be on his guard. The tremor is, further, the earliest symptom in the majority of cases. When present, it is rhythmic and relatively slow and coarse, while its range is variable. It almost invariably persists during rest and is temporarily inhibited by voluntary action as well as by passive movement, and probably also by other influences, although subsequently it may be resumed with its original or even with increased intensity. Rarely it has been absent or slight even during rest, and it has been induced or increased by voluntary action. It is aggravated by observation and emotional influences, but it ceases during sleep, and sometimes also in members paralyzed as a result of intercurrent organic disease of the brain. It often differs in degree upon the two sides of the body, more especially in the upper extremities, although when both sides are involved, the movements of the two sides are synchronous, it generally appears first in the upper extremities, especially the hands and fingers, and it may extend in monoplegiform, hemiplegiform or paraplegiform manner. The movements sometimes appear purposive, and resemble those that would be made in rolling pills or in holding a pen or in spinning wool. I am in the habit of describing them as intrinsic, because, unlike those that attend other forms of tremor, they appear to take place within the member rather than at its extremity merely. They seem, at times, to consist almost wholly in active flexion with reactive extension. I have found the frequency of movement to vary between 4.5 and 8.9, averaging, however, 5.9 oscillations per second.[1] The accompanying tracings will illustrate the frequency of the movement, its range—magnified—and its synchronousness on the two sides of the body, notwithstanding its predominance on one side, as well as the influence of voluntary and of passive movement. It has long been recognized, however, that the tremor is not absolutely constant, and its absence does not invalidate the diagnosis.

---

* Read before the Medical Society of the State of Pennsylvania, at Wilkesbarre, Sept. 20, 1900.

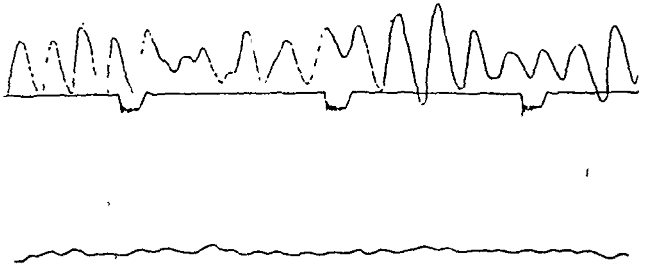

Fig. 2.—The movements of both hands recorded simultaneously. The upper curve represents the movement of the right hand; the lower, that of the left. In the latter the inhibiting influence of voluntary action is illustrated. The tracing exhibits the synchronousness of movement on both sides. The interrupted straight line represents time in seconds. To be read from left to right.

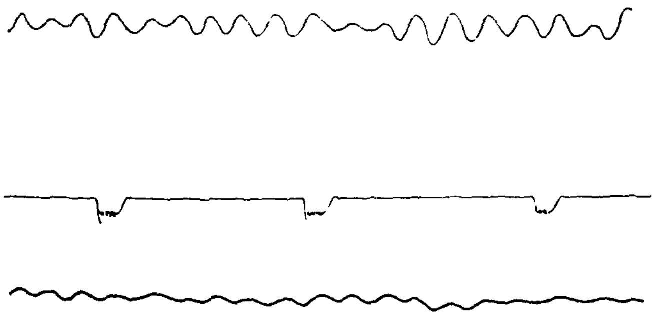

Fig. 3.—The upper curve represents the movement of the right hand; the lower that of the left. The interrupted straight line indicates time in seconds. Movement from left to right. Frequency, 6 1-3 per second. The tracing exhibits synchronousness of movement on the two sides, although the range of movement is greater on the right.

Not less distinctive than the tremor is the impairment of mobility. This has been attributed to muscular rigidity, to delayed transmission of volitional impulses from the cortex, and to muscular weakness. It attends efforts at both active and passive movement. It is this symptom that is responsible for the peculiar appearance and attitude of the patient. The face has, as a rule, a fixed, stolid, unemotional expression. The body often presents a forward inclination, the shoulders being round and stooped and the patient has a tendency to run forward. The knee-jerks are at times irritable and excessive, and occasionally there is abortive ankle-clonus. When rigidity is marked, the reflexes may be inhibited mechanically.

Among other symptoms of a subordinate character, are a sense of undue heat and increased sweating; a feeling of restlessness is also not an uncommon manifestation, necessitating frequent changes of posture and interfering with sleep. The patient is often depressed, though occasionally cheerful. There is, as a rule, no pronounced mental impairment, although failure of memory may be complained of.

Little is known of the etiologic factors responsible for the development of paralysis agitans. Direct inheritance of the disease is rare, although an indirect neurotic heredity is not infrequent. The disorder is more common in men than in women, and most so between the ages of 40 and 50. Antecedent infectious disease or intoxication has in some instances been thought to be operative. The onset is generally insidious, exceptionally acute, and the course is slowly progressive. The first symptoms not rarely follow profound emotional disturbances, long-continued overexertion or traumatism, and they may appear in the member specially affected.

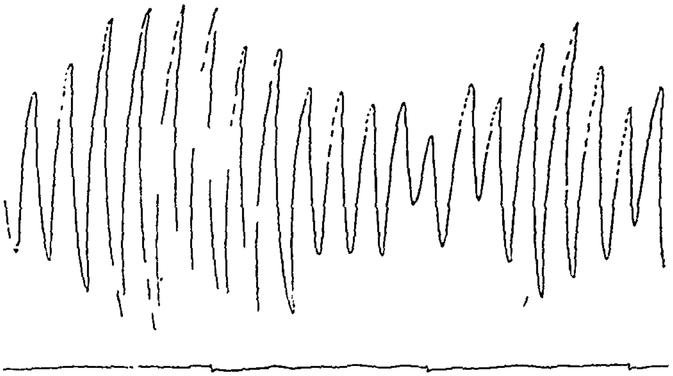

Fig. 4.—The above represents 3½ seconds. Movement from left to right. Frequency, 6 per second.

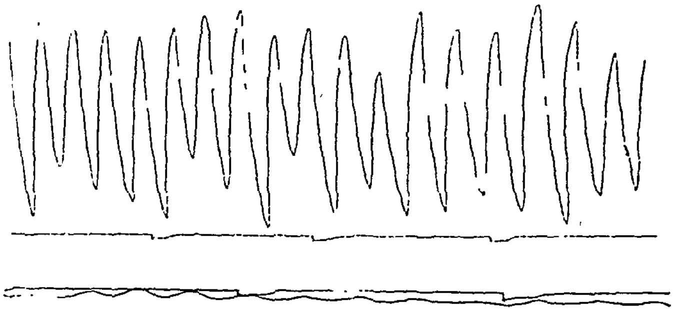

Fig. 5.—The upper curve exhibits the frequency and rhythm of movement, the lower apparently spontaneous inhibition, as well. The interrupted straight lines represent time in seconds. To be read from left to right.

The disease is one of the predegenerative period, and such lesions as have been found are not unlike those that attend senility. The disease is progressive and generally protracted in course, and not amenable to curative treatment. There may be remissions and exacerbations in the symptoms, or they may appear to be stationary. The patient eventually becomes incapacitated for his usual pursuits and death ultimately results from exhaustion or intercurrent disease.

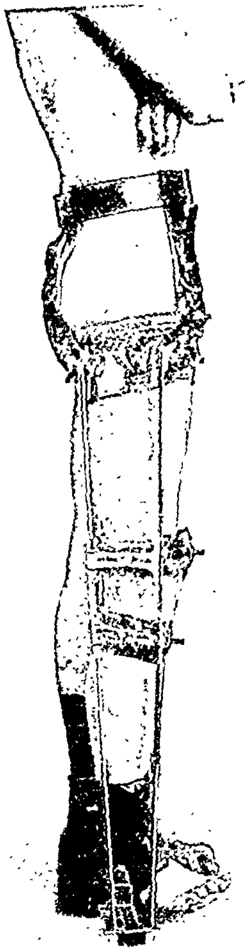
Various palliative measures may, however, be employed, such as the administration of hyoscin or hyoscyamus, gentle exercise, active and passive, and the observation of general hygienic precautions.

---

[1] Journal of Experimental Medicine, vol. ii, No. 3, 1897.

the treatment of fractures of the arm, and of fractures, deformities and diseases of the leg and hip-joint, the writer has constructed splints for the upper and lower extremities, each embodying the same general principles, so that a description of any one will suffice. The splints consist of inflatable cushions, in combination with adjustable stays, arranged in such a manner that there is no solid contact any where on the limb.

Each part of the splint is simply and easily adjusted. The cushions prevent any injury from pressure, and over the ankle they are arranged vertically with interspaces to permit of free circulation while securing extension. The leg or immobilizing cushions may be segmented if desired, but as the bones are not so superficial as at the ankle, and as there is no traction on the cushions, this is not necessary. The hip-cushion grasps the thigh at the angle of the pelvis, and is arranged so that it can be made to follow the angle of the right or left thigh, as desired. The sock grasps the leg at the ankle, with interspaces between its vertical cushions. By means of the adjustable stays, extension and counter-extension is made between these points with turn-screws and key. With solid metallic connection between these cushions, the degree of separation on which the adjustment depends remains the same, no matter what position is assumed.

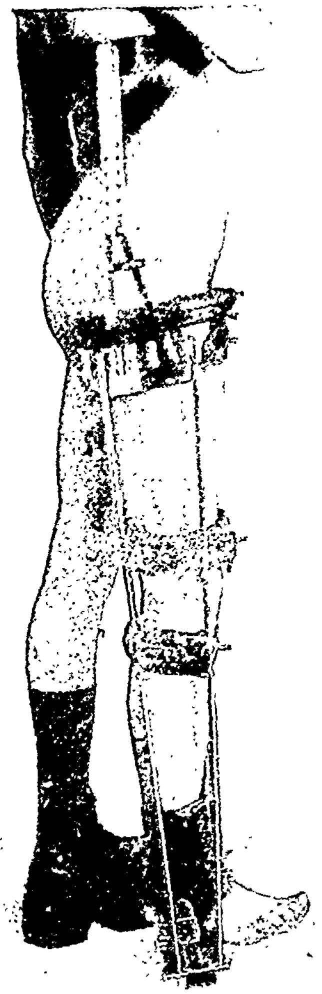


Pneumatic splint with belt suspender attachment for walking.

Shortening is prevented in fractures of the leg and thigh. Immobilization is secured by the aid of the leg-cushions, and clips connecting the stays, and is under full control, deformity being prevented, as well as shortening. When the splint is applied, the foot does not come into contact with the foot-plate.

In the ambulatory treatment, when the weight is placed on the foot-plate, it is received by the pelvis, the leg being in a "sling," suspended from the pelvis. A cane should always be carried, but where desired, a crutch may be substituted.

The shoe of the opposite foot should be raised, to match the raised foot. The erect position, with a limited amount of exercise, will tend to preserve the general health, increase the circulation, hasten absorption, and promote growth and repair, this, with the accuracy of adjustment which preceded it, and can be secured by this method, limits the amount of softening and absorption, hastens the time of healing, and avoids the usual muscular atrophy which accompanies fractures owing to disuse of limbs and circular constriction.



Pneumatic splint with immobilizing hip-joint attachment for walking, the adjustable belt not shown in illustration.

Bandaging to assist in retaining the fragments in apposition should pass from the leg or arm to the stays, for better support and to avoid circular constriction.

The suspender attachment supports the weight of the splint, from the body, and is adjustable.

The accurate coaptation secured by this method reduces pain, lessens the amount of softening and absorption, and hastens convalescence. By avoiding circular constriction, we limit the amount of exudation, facilitate growth, repair, and absorption; avoid ischemia and stiff joints.

Is circular compression adequate to maintain the apposition of the fragments? Experience in fractures of the upper third of the femur has shown that circular compression, no matter how applied, can not by itself maintain apposition. What is true in the upper third

The tremor of paralysis agitans is to be differentiated especially from that of senility, of alcoholism and other forms of intoxication, from the incoördinated movements of multiple cerebrospinal sclerosis and from hysterical tremor. Senile tremor, however, rarely, if ever, begins in one member or on one side, but generally is distributed uniformly. It is usually fine and frequent, slight or absent during rest, is increased by violent effort, is not associated with rigidity, occurs later in life, and is not progressive in course. The various forms of toxic tremor, likewise, are fine, frequent, general, slight or absent during rest, increased on voluntary action, and unassociated with rigidity. They may, of course, occur at any time of life, although more common during active adult existence, and in conjunction with other more or less distinctive symptoms. A history of exposure to the exciting influence is of decisive importance in the diagnosis. The movements of multiple sclerosis are coarse and somewhat unlike ordinary tremor, being rather incoördinate and wanting in rhythm. They are also generally absent during rest and are induced only by voluntary effort, and are often associated with lesions of the fundus of the eye, with nystagmus, scanning speech and derangement of micturition, while rigidity is not likely to be present and the peculiar facies of paralysis agitans is wanting. The tremor of paralysis agitans is to be differentiated from that of hysteria by the association with the latter especially of other hysterical stigmata and by the influence of suggestion.

Paralysis agitans without tremor is not so common that the report of two cases recently under observation in which tremor was the least conspicuous of the symptoms may not be without interest. Both patients were seen at the Orthopedic Hospital and Infirmary for Nervous Diseases, the one in the service of Dr. S. Weir Mitchell and the other in that of Dr. Wharton Sinkler, to both of whom I am indebted for the privilege of making this report.

S. S., a plumber 50 years old, presented himself for what he designated nervousness. He suffered from mental confusion, with depression and introspection. There was also weakness of the legs, more marked on the left. For several years there had been stiffness, which began with a cramp-like feeling in the left foot, and extended to the shoulder and elsewhere. Slight tremor was noted and this the patient stated occasionally became quite marked, although at times it was scarcely, if at all, appreciable. The patient presented the typical appearance and facies of a case of paralysis agitans. The face was fixed and immobile, the attitude was stooped forward, the speech was slow, the voice low and monotonous, and all movements and apparently also cerebration appeared slow. The knee-jerks were small and station was steady. The pupils were full, equal, regular, reactive to light. The grasp was firm, the dynamometric register being 170 on the right and 130 on the left. There was some tendency to propulsion. The action of the heart was rhythmic and the sounds clear. The radial artery was stiff and the tension plus. Memory was impaired; sleep was poor; the bowels were constipated. The patient was easily chilled and suffered readily from cold, and under such circumstances the hands became cyanotic. The urine presented no abnormality. The man once had gonorrhea, but there was no evidence of syphilis. He had used alcohol, tobacco, coffee and tea only in moderation. He had suffered business reverses and one of his daughters was neurasthenic from overstudy.

J. H., a woman 68 years old, presented herself on account of weakness in the lower extremities and in the back, with difficulty in walking. There was slight tremor in the right hand on voluntary movement. The countenance was rather fixed. Speech was slow and the gait decrepit. The knee-jerks were slightly exaggerated, but there was no ankle-clonus. On inspection it was found that both hands were tremulous when held out, but not when in action or at rest. The tremor was said to be more marked on some days than on others. Station was unsteady, the patient yielding toward the right, as she did also in walking. In attempting to walk there was some delay in starting out, and all movements were performed slowly. The action of the heart was rhythmic, the first sound clear, the second greatly exaggerated. The pulse, though not strong, was of increased tension. The pupils reacted to light. The patient suffered from no sense of undue heat, and from no excessive sweating. An additionally interesting feature of this case is the fact that a daughter 47 years old, who merely accompanied her mother and did not seek treatment, presented a distinctly cretinoid appearance. She had not learned to walk until the age of 3, although she spoke clearly and subsequently did well at school. Menstruation had not begun until the age of 22. The patient was short of stature, measuring only 4 feet 6 1/2 inches in height. The thyroid gland, especially the right and middle lobes, was found enlarged, and is said to have been so for seven or eight years. The complexion was pale and muddy, and the skin wrinkled; but there was no thickening of the subdermal tissues. The tongue was rather large and rough, and intelligence appeared deficient. There was no tachycardia and the eyes were not prominent. The knee-jerks were active, but there was no ankle-clonus.

While it can not be strictly said that in the two cases of paralysis agitans which I have reported the tremor was wholly absent, it was at times so inconspicuous as not to be viewed as a symptom of importance, much less of diagnostic utility. The main object of this communication is to invoke renewed attention to the fact that the disorder under consideration may be unattended with tremor, and further that this, when present, may be accentuated by voluntary action.

NEW METHODS FOR THE APPLICATION OF OLD PRINCIPLES IN THE TREATMENT OF FRACTURES AND DEFORMITIES OF LIMBS.

JAMES G. HUGHES, M.D.
SHEBOYGAN, WIS.

In all cases of fracture, to restore and maintain the limb in its normal position, extension and counter-extension between bony prominences, or a flexed segment of the limb, above and below the fracture, must be employed.[1] To this must be added immobilization, when normal position of the limb is accurately secured. In addition to the above principles, the open dressing, in compound fractures, is of primary importance for obvious reasons. Every splint should permit of inspection, bathing, ventilation, etc. There should be no circular constriction of the limb to retard the circulation. The effects of impaired circulation, delayed union, ischemia, stiff joints, and in some cases non-union, can be ascribed to this interference.

It is safe to say that fully one-half the fractures of the leg should be treated by the ambulatory method. Many patients assume the erect position in spite of the warnings of their medical attendant. The patient suffering from a fracture of the leg, or thigh, is asked to assume the recumbent position until nature repairs the solution. The principles governing the treatment of fractures are the same in the erect as in the recumbent position, and can be applied in one case as well as in another, and if these principles are fulfilled, displacement can not occur in either position.

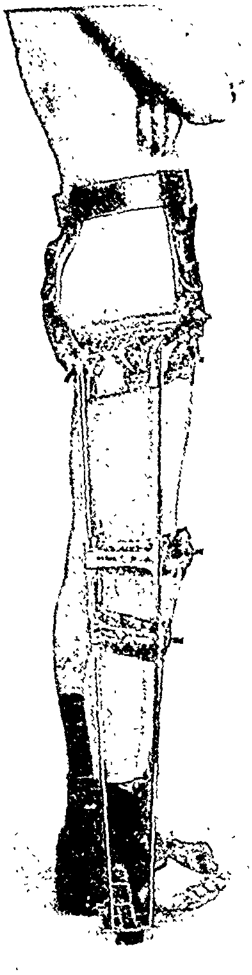
With a view of embodying the above principles in the treatment of fractures of the arm, and of fractures, deformities and diseases of the leg and hip-joint, the writer has constructed splints for the upper and lower extremities, each embodying the same general principles, so that a description of any one will suffice. The splints consist of inflatable cushions, in combination with adjustable stays, arranged in such a manner that there is no solid contact any where on the limb.

---

[1] American Text-Book of Surgery, 1893, p. 287.

Each part of the splint is simply and easily adjusted. The cushions prevent any injury from pressure, and over the ankle they are arranged vertically with interspaces to permit of free circulation while securing extension. The leg or immobilizing cushions may be segmented if desired, but as the bones are not so superficial as at the ankle, and as there is no traction on the cushions, this is not necessary. The hip-cushion grasps the thigh at the angle of the pelvis, and is arranged so that it can be made to follow the angle of the right or left thigh, as desired. The sock grasps the leg at the ankle, with interspaces between its vertical cushions. By means of the adjustable stays, extension and counter-extension is made between these points with turn-screws and key. With solid metallic connection between these cushions, the degree of separation on which the adjustment depends remains the same, no matter what position is assumed.

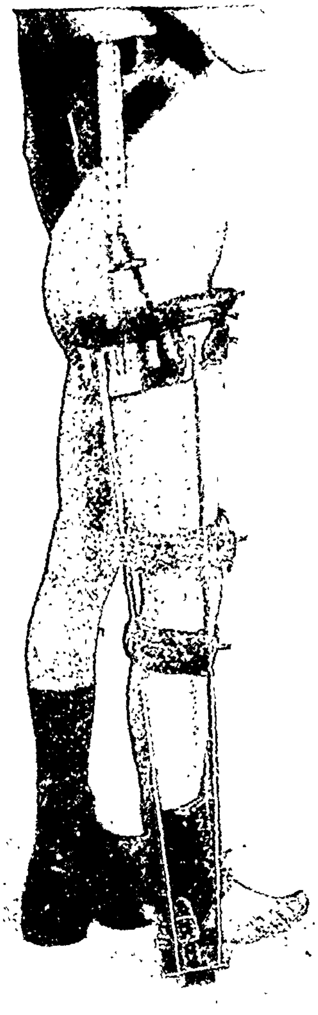
Shortening is prevented in fractures of the leg and thigh. Immobilization is secured by the aid of the leg-cushions, and clips connecting the stays, and is under full control, deformity being prevented, as well as shortening. When the splint is applied, the foot does not come into contact with the foot-plate.



Pneumatic splint with belt suspender attachment for walking.

In the ambulatory treatment, when the weight is placed on the foot-plate, it is received by the pelvis, the leg being in a "sling," suspended from the pelvis. A cane should always be carried, but where desired, a crutch may be substituted.

The shoe of the opposite foot should be raised, to match the raised foot. The erect position, with a limited amount of exercise, will tend to preserve the general health, increase the circulation, hasten absorption, and promote growth and repair, this, with the accuracy of adjustment which preceded it, and can be secured by this method, limits the amount of softening and absorption, hastens the time of healing, and avoids the usual muscular atrophy which accompanies fractures owing to disuse of limbs and circular constriction.



Pneumatic splint with immobilizing hip-joint attachment for walking, the adjustable belt not shown in illustration.

Bandaging to assist in retaining the fragments in apposition should pass from the leg or arm to the stays, for better support and to avoid circular constriction.

The suspender attachment supports the weight of the splint, from the body, and is adjustable.

The accurate coaptation secured by this method reduces pain, lessens the amount of softening and absorption, and hastens convalescence. By avoiding circular constriction, we limit the amount of exudation, facilitate growth, repair, and absorption; avoid ischemia and stiff joints.

Is circular compression adequate to maintain the apposition of the fragments? Experience in fractures of the upper third of the femur has shown that circular compression, no matter how applied, can not by itself maintain apposition. What is true in the upper third is also true, in a lesser degree, in other places. The beneficial effects of circular constriction with bandage and cast, has been over-estimated, while its dangers and disadvantages have been too little commented on, if they have been fully appreciated. Open dressings facilitate inspection, dressing, bathing, ventilation, massage, and any indicated treatment, the importance of which needs no emphasis. The attachment for immobilizing the hip-joint is applied in fractures of the neck of the femur, and also used in hip-joint diseases, and is on the same principle as that now in vogue. When the key is removed and the caps replaced, the splint is locked, and the adjustment can not be interfered with. The pneumatic pads are covered with satin-finished waterproof leather, and can be cleaned with warm water and soap when necessary.

The splints are easily worn under the regular clothing, and are so well constructed that they will last practically a life time.

They have been tested by the writer in some severe cases, with perfect results; among them, one case of compound, comminuted, multiple fracture of both legs. The bones in the right leg penetrated the skin in five different places, and in the left leg, in three. Several loose fragments of bone had to be removed. The usual dressings were tried, but had to be abandoned on account of the excrutiating pain and stasis. Amputation of both legs was considered necessary by attending physicians, but the patient would not submit to it, and further counsel was called, resulting in the application of pneumatic splints to both legs. The pain ceased at once, on application. The absence of circular constriction allowed complete restoration of the circulation, and permitted of proper open dressings for the wounds. The splints were only worn thirty-three days; ankle and knee motion was in no way impaired; the union and result was perfect.

I mention another case, on account of the attending circumstances, one of simple fracture of the tibia. The patient was erecting a house at the time, and hauled lumber seven miles daily, without discomfort and with perfect result.

Before bringing the appliances to the notice of the profession, they were submitted to some of our most eminent surgeons, whose unqualified endorsement has demonstrated the unparalleled excellence of the treatment.

POSSIBILITIES OF LIQUID AIR TO THE PHYSICIAN.*

A. CAMPBELL WHITE, M.D.
NEW YORK CITY.

It is now over a year since I began the use of liquid air in the hospitals of New York, and less than a year since I published in the *Medical Record* a preliminary report of the results obtained by its use up to that time; and I am led to-day to accept your invitation to present this subject to your Section, no less by the pleasant recollections of the last time I appeared before you, than by the many communications I have received since publishing my report, from all parts of the world, demonstrating the lack of knowledge of the public as well as physicians as to what liquid air really is. I have received requests from physicians from nearly all parts of the United States, from Mexico, from Germany and even from New Zealand, asking that a small package be sent and all expense would be paid at the other end. I have been asked whether it were given hypodermatically, and whether it would not be good taken in small doses internally for abscess of the liver. One physician, who has represented many drug houses, wanted to know if it could not be put up in small packages and retailed at the drug stores and whether he could not act as my Southern agent. Nearly all physicians say, in discussing the subject, "Oh, we have tried extreme cold before and know it is no good." Possibly there are some of you here this afternoon who have never seen liquid air, and if so, I shall demonstrate that you really never knew what cold was before. I intend at least to show you what liquid air really is, and have brought with me, through the courtesy of the Tripler Liquid Air Company, a generous supply in order that I may show you its physical properties and demonstrate some of its applications, as well as show you some of the appliances which more directly concern us.

After doing this, I desire to briefly tell you of some of the things we have accomplished with it at the Vanderbilt clinic of Columbia University, and elsewhere; and then call attention to some of the things which may be done in the treatment of internal diseases. [Dr. White gave several demonstrations with liquid air.]

In my former paper I told of the results of our attempt to kill germs with liquid air. With Dr. William H. Parks, we tested the effects of liquid air on typhoid, anthrax and diphtheria bacilli. In order first to test the effect of extreme cold on these germs without bringing them in direct contact with the liquid, we put into a number of capillary tubes pure cultures of virulent anthrax, diphtheria and typhoid bacilli. These capillary tubes were marked for identification, sealed at both ends, and dropped into a glass of liquid air. The liquid was renewed at intervals, so that the tubes were at all times completely submerged. Some were removed in thirty minutes, others in forty-five minutes, sixty minutes, and ninety minutes. After they were removed from the liquid and the sealed ends were broken, they were dropped into separate culture-tubes containing fresh sterilized bouillon, and these in turn marked for identification. These bouillon tubes were placed in incubators kept at a temperature of 38 C., where they remained for over forty-eight hours, when they were all examined and found to contain pure cultures of anthrax, typhoid and diphtheria bacilli according as they had been inoculated. In order to test whether liquid air itself in addition to its temperature would have any effect on germ life, a culture-medium containing numerous colonies of anthrax bacilli was dropped into a glass of liquid air and allowed to remain over an hour. When removed, a fresh sterile culture-medium was inoculated with the one exposed to liquid air and placed in the incubator as before. The same result was obtained as when the capillary tubes were exposed.

Dr. J. H. Huddleston tried the effect of liquid air on vaccin virus, and found that fifteen minutes' or less exposure to the liquid air had no effect whatever on the power of the virus to produce vaccination.

Longer exposures to liquid air have been tried with the same result. Dr. Park has recently made further experiments, making the exposure over two hours and exposing all kinds of germ life in form of pure virulent cultures, from hay infusion to anthrax bacilli. With this exposure, taken all together, from the weakest germs to the strongest, it kills from 98 to 50 per cent. Of the typhoid germ it kills about 75 per cent. in two hours' exposure, the staphylococcus about 50 per cent., and the diphtheria typhoid, about 65 per cent. This exposure does not completely destroy the virulence of any pure culture, but of course the activity or virulence of all these germs is suspended for a long time after exposure to the liquid air, and they are only brought back to activity by the most careful handling and under the most suitable conditions. Professor Dewar, of London, is reported to have given bacteria exposure to liquid air for two weeks, with practically the same results.

---

* Presented to the Section on Diseases of Children, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Now the question is, knowing these facts, what is the effect of liquid air upon germs existing in the living tissues of the body. We know that the human organism is the natural enemy of the bacillus. We have reason to believe that the human system develops an antitoxin when invaded by the ptomain-producing bacteria, which under most conditions is successful in withstanding this invasion. Is it not possible that the temporary suspension of the vitality of these germs, due to the application of liquid air, gives nature the opportunity to completely destroy them, particularly when we remember that the local circulation is much increased shortly after the application.

Buchner,[1] in an article on the natural defenses of bacteria, speaks of the results obtained by us in the use of liquid air, and attributes all our success to the subsequent local hyperemia produced.

CLINICAL USES OF LIQUID AIR.

Liquid air, applied to the healthy living tissues, causes a temporary local anemia accompanied by anesthesia, or a slough, depending upon the amount used.

The results obtained by an excessive application are best explained by the experiment performed on the rabbit, before we had used the liquid air on the human body. About three-quarters of the ear of a rabbit was completely frozen by placing it in liquid air for some minutes. The ear was frozen so stiff that a small piece of the tip was broken off with the fingers without pain or hemorrhage. In less than ten minutes' time the circulation was entirely re-established with hemorrhage at the point where the piece had been broken off; the frozen part had regained its normal temperature—possibly a little higher—and color. The ear remained perfectly normal for about five days, when it began to swell somewhat, and by the end of two weeks about one-half of the frozen part had shriveled and dropped off. The remainder of the ear regained its normal condition. The part to which the liquid air is applied—with the spray—immediately loses all the blood, becomes perfectly colorless and is accompanied in the application by no pain excepting a slight tingling sensation which is only felt at the very beginning of the application. If only a slight amount is used the circulation almost immediately returns, the part becomes congested and frequently elevated, looking like a wheal or urticaria; this subsides soon and may or may not for a while itch to a slight extent. The anesthesia lasts not only while the anemia exists, but for some time after, owing to a temporary paralysis of the sensory nerve terminals. A freezing sufficient to produce anesthesia for ten minutes can be given without causing any more destruction of tissue than a slight desquamation of the superficial epithelium, which in no way interferes with primary union.

I recently did an operation under the influence of local anesthesia produced by liquid air, for the purpose of relieving a deformity of the hand resulting from a poorly-treated burn of childhood. The hand was freely incised, and the fascia cut here and there, relieving whatever adhesions existed. The operation caused no pain, the result was perfect, and primary union was in no way interfered with. I could mention any number of cases equally successful where liquid air has been used as an anesthetic.

I think you can readily appreciate in how many cases this anesthesia would be preferable to any other, for example, opening of an abscess, where there is always an element of some danger in the use of cocain; incising a paronychia; and of what great value it would be in a cardiocentesis, paracentesis thoracis or abdominis, where the vital functions are already at so low an ebb as to preclude the use of anesthetics.

In this connection I will just mention the almost invariable success resulting from the application of liquid air in the same way over the spinal end of the nerve in neuralgias and herpes zoster. The pain ceases almost immediately; rarely is more than one application necessary, and the only bad result has been some ulcerations at the point of application in some patients of advanced years, where the vitality of the skin was exceptionally low. These ulcerations readily heal with proper treatment, and are, as a rule, a pleasant substitute for the pain of neuralgia and herpes zoster.

As a cold application to allay or abort an acute inflammation, its use is ideal, and should be applied intermittently with the roller. The same would apply to an acute adenitis—not neglecting to treat the cause.

In the treatment of a boil I would use the spray, and, if just beginning, I would completely freeze it, possibly pricking it while frozen here and there with a needle, in order to relieve any subsequent congestion. If pus to any extent had formed I would freeze and make small incisions. It will always abort a boil if taken in time, although of course not preventing others forming.

From my experience in the local treatment of carbuncle with liquid air I am satisfied from every point of view that this is by far the best form of treatment. It is less painful to the patient than any other form of treatment. Only one application is necessary; within twelve hours of the first application, the pain entirely ceases, not to return again, and at the end of a few days only a small ulcer is left—representing the tissue between the openings of the carbuncle—which readily repairs with usual dressings. In the treatment of the carbuncle the spray is used, first projecting it into the openings and using the air quite freely, then quite thoroughly freezing the external surface, which must be well cleansed of discharge resulting from sending air inside of the carbuncle before freezing. After freezing, the carbuncle should be dressed with a dry absorbent dressing, so that the discharge, which will be abundant and accompanied with considerable bleeding, can be readily absorbed. The reaction from the freezing takes place in about twenty minutes, and it is to this extreme hyperemia that I attribute the success of liquid air in the treatment of this affection more particularly.

Before using liquid air in lupus we anticipated success, and our expectations have been realized, both in the treatment of the erythematous form and in lupus vulgaris. In the former variety we use the cauterizing instruments frequently, not freezing to any great extent at each application. Excessive desquamation results after each application, until good healthy skin appears, slightly reddened. The applications are then stopped and the redness soon disappears. Lupus vulgaris is treated rather generously with the spray once or twice. This causes a slight acute inflammation, which results in a healthy ulcer that quickly heals.

---

[1] Münch. Med. Wochschr., Oct. 3, 1899.

As a stimulant in the treatment of chronic ulcers, varicose and non-specific, one application, not to the point of freezing, but intermittently for about five minutes with the spray, is of great utility.

Liquid air as a cauterizer is probably the first thing that would occur to us after having seen and handled it, particularly for the removal of the benign foreign growths. For this purpose we now use liquid air to the exclusion of almost all other methods. For the quick and comparatively painless removal of a nevus, without any resulting scar, it is not equaled by anything we now have at our disposal. I have already shown you the instruments for its application in this direction for the destruction of adenoids, polypi, nevi and other hypertrophies.

The study of carcinoma has been universal and popular during the last few years, and this study promises to disclose the true cause of this dreadful and undoubtedly increasing malady. No doubt when its true etiology has been established we will find some treatment which will prove either prophylactic or curative. I think we must all have been impressed who have seen many of these cases, with the utter futility of almost every method of treatment at our disposal; even surgery seems to give in nearly all cases only a temporary relief, to be followed by even more malignant growth. The consideration of cancer is certainly not a subject of discussion for this Section, but I would not be doing justice to my subject did I fail to mention the great good liquid air has done in these cases. Even in cases in which the treatment has failed to cure, which were far beyond operative interference, where the patient has had two or three operations, where the patient has had every "special treatment," quack and otherwise, in the country; even in these cases, the great good done in the relief of pain and the destruction of bad odor, both so characteristic of this disease, places liquid air in efficiency far above any other treatment we have to-day.

In my previous paper I said I could make no claim for liquid air in the treatment of cancer, for my limited experience at that time, though promising, did not warrant my offering any encouragement; I can truly say to-day that I believe that epithelioma, treated early in its existence by liquid air, will always be cured, and that many cases inoperable can also be cured by its application. Prof. George H. Fox, in one of his lectures in the College of Physicians and Surgeons, New York, presented last autumn one of the first cases treated at his clinic by liquid air. This patient, a woman some 60 years of age, had an epithelioma on the right face, involving the outer canthus of the right eye. Professor Fox, in presenting this case, said, "No treatment at our disposal could have destroyed an epithelioma of this character in so short a time and with so slight a scar remaining as liquid air has done in this case." This subject requires a paper devoted entirely to its consideration, and I am sorry I can not present the history of some of these cases in detail, those which have recovered and those less fortunate, for every one bears testimony to the efficiency of liquid air in the treatment of carcinoma.

When we come to consider the use of liquid air in the treatment of non-cutaneous diseases, there is a very broad field open to us and many obstacles present themselves which are difficult to overcome. I think it will at once occur to us all that we ought to be able to use this cold, dry vapor given off by liquid air, for the reduction of temperatures in fevers in something the same manner as we now give hot air and steam baths to promote activity of the skin. We are now having made an apparatus which we hope will accomplish this result; if so, it will be much more simple than the cold plunge and be much more pleasant and agreeable to the patient, accomplishing at the same time the desired results.

I have also thought that the inhalation of this vapor, which is almost pure oxygen, would be of great value in the treatment of certain diseases of the air-passages, such as hay-fever, acute laryngitis, tubercular laryngitis and possibly pulmonary phthisis. For this purpose I am having made an inhaler which will carry the vapor well back over the glottis before it becomes warm; and, furthermore, this vapor can be medicated, and in this way carry with it some remedy which might possibly add to its efficiency. The results of this treatment are, of course, purely speculative, but I anticipate success in this direction in the treatment of at least some of the diseases mentioned.

I regret that time does not allow me to go more fully into details regarding some of the cases I have treated with liquid air; but if I have given you all a fair idea of what liquid air is, what it looks like and what some of its possibilities are to us and to our patients, I shall feel well repaid for undertaking this demonstration, and I hope the discussion which is to follow will bring out many new points we have not thought of before.

DISCUSSION.

Dr. Louis Fischer, New York City—It seems to me that the question of local anesthesia is one of great importance to pediatrists, as for instance in the treatment of scrofulous manifestations, local abscesses, suppurative adenitis, various forms of peritonsillar abscess and the removal of adenoids of the pharynx.

Dr. Waher.—In the treatment of carbuncle, is your object to establish a slough?

Dr. A. Campbell White—There are usually four openings around the center, forming, so to speak, the corners of a square. These corners will slough, but not the edges. The good results in carbuncle I believe to be partially due to the fact that these openings exist. The excessive congestion which comes on after the application of the liquid air is relieved by a free discharge through these openings. There is only a temporary suspension of the activity of the bacilli.

Dr. L. J. Lautenbach, Philadelphia—Did you freeze and operate with the knife upon the case of epithelioma at the side of the eye?

Dr. White.—No, we used the liquid air cauterizer and simply closed the eye. When liquid air strikes the skin it is for the moment at a temperature of 312 F. below zero. I should freeze slightly, then wait and repeat the operation perhaps three or four times. The woman referred to had twelve treatments. There was a marked and edematous inflammation of the side of the face. It subsided in about three days. After that the improvement was very decided. This has been true of almost all cases. I have applied liquid air in epithelioma of the tongue. Here there is so much moisture that inflammation is easily excited, so that this agent must be used with great care. In two cases, one in the anterior part, and the other in the posterior part of the tongue, I have used the liquid air. After about three or four applications it was necessary to temporarily stop treatment because of the inflammation induced. Great care must be observed in posterior cases for fear of the possibility of edema of the glottis arising. Almost no sloughing follows the application of liquid air. The destruction is very superficial as we use it. In a case of carcinoma of the face we break up the intercellular substance of the epithelioma by freezing, and destroy the nutrition of the superficial cells. When the patient first returns there is a small ulcer, and we repeat the application. Eventually there is no further return. I would not dare to put a glass instrument into a child's throat for removing adenoids; I should prefer to make use of one made of thin aluminum. I have treated erysipelas by filling a glass globe with liquid air and rolling it over the surface. For local refrigeration I have made use of a brass roller into which liquid air is introduced, and then the roller is passed over the part.

MOVEMENTS OF INTESTINES.*

ALBERT BERNHEIM, M.D.
PHILADELPHIA.

During treatment of a woman for floating kidney, nervousness and general debility, I administered—in the course of a rest-cure—enemas of cottonseed-oil; one time, about five hours after the injection, the patient vomited, the vomit for a greater part proving to be cottonseed-oil, this incident showing the possibility of a retrograding current of the oil from the rectum to the stomach. These oil enemas were administered for over two weeks and it was only this one time that oil was vomited. I was induced by this fact to make some experiments with injections into the rectum of a negro; these will be mentioned later on; besides I used a black-and-tan dog for experimenting, and, later on, in treating a woman for mechanical gastric insufficiency with a subacid condition, in which vomiting was not infrequent, the nutrient enemas used served as experiments.

It is for the research into the consumption of such nutrient enemas that various investigators experimented on the movement of the intestines, to learn of possible antiperistalsis of the gut.

Celsus (3-5 B. C.) mentioned the efficiency of nutrient enemas; in 1869 Voit and Bauer, in Munich, investigated their value as to absorption in the body, and found that an egg-emulsion, with the addition of a pinch of sodium chlorid, will be easily absorbed by the mucous membrane of the rectum and colon. Eichhorst, two years later, observed the same results. Czerny and Latschenberger, experimenting on men, found that not only albuminates, but also fat in emulsion and paste of starch, would be absorbed, when introduced into the rectum; they could not determine whether the starch is converted into sugar or not before the absorption, and it remained doubtful where the absorption occurred. Leube thought it necessary to peptonize the enema by mixing it with pancreas before injecting it into the rectum. Ewald, making a greater series of experiments, declared the peptonizing process superfluous, finding that an emulsion of egg-albumen will be absorbed even without the addition of sodium chlorid. Huber took an intermediate position between Voit and Bauer and Eichhorst on the one side and Ewald on the other; he recognized the fact of absorption without sodium chlorid, but the absorption was better with an addition of salt. Hemmeter explains the absorption without an addition of sodium chlorid, because this salt is naturally present in the egg. The absorption of the enemas was always said to occur in the lower and lowest parts of the bowels. L. Landois, in his book on physiology, says that the ileocecal valve prevents in general the contents of the colon from re-entering the ileum. When liquid masses are injected gradually into the rectum through a tube, they may get above the ileocecal into the ileum. In 1884, Nothnagel saw antiperistaltic movements of the gut when he touched the exposed intestinal section with a crystal of sodium chlorid or injected a salt solution by means of a Pravaz syringe. Grützner thought the fact of this antiperistalsis a chief point as to the effect of nutritive enemas. His experiments were made on white mice, rabbits, guinea-pigs and cats, which had hungered for twenty-four hours. The injection mixtures consisted of a physiologic salt solution, with animal coal or starch or finely cut horse-hair or sawdust or poppy seeds. Four or six hours after the injection Grützner found the introduced particles in the stomach and in the entire course of the gut, except in the rectum. When, instead of salt solution, distilled water or a solution of .1 per cent. hydrochloric acid or of .6 per cent. potassium chlorid had been used, the introduced particles could not be discovered in the upper parts of the alimentary canal. Grützner at the same time took such precautionary measures that the animals could not have swallowed any excrements. The same positive results were found by him in experiments on man, in whose rectum he had injected starch emulsion.

Christomanos imitated these experiments and found that his researches corresponded to those of Grützner, if he followed the latter's method, but if he subjected the animals to extraordinary measures, such as severing and ligating the esophagus or fastening them down to the vivisection table for up to six hours, or applying the mouth-clamp, the experiments were negative. The latter series of experiments were made under rather pathologic conditions, and therefore can not prove what they seem to show. His experiments were made with carmin, Prussian blue, lycopodium dyed red or blue, and alcanna-oil, on white mice, rabbits, frogs, pigeons and men. Only two out of ten experiments made on men were positive; in these cases he used either lycopodium or bismuth subnitrate, but lycopodium is often unseen in the microscope, and the bismuth crystals are not always to be recognized as such, even if stained black through the abode in the intestines.

Dr. Swiezynski, in the clinic of Professor Riegel, tried the same kind of experiments on men and dogs. In 12 cases, unstained lycopodium had been introduced 7 times, in 6 instances in a physiologic salt solution; the 6 times were positive; in the seventh case 1 grain of lycopodium; in the eighth and ninth cases, lycopodium stained with nitrate of silver in a salt solution was used, and in both instances grains of lycopodium were found in the stomach. In 2 other cases lycopodium stained with gentian violet was introduced, once with sodium chlorid and with positive result; the other time without addition of salt was negative. In the twelfth case bismuth subnitrate was used; this experiment could not be regarded as absolutely positive. Six other experiments were made with gentian violet lycopodium, 4 times in sodium chlorid solution, and twice without the salt; these were more or less positive.

Dr. Dauber made 17 experiments on white mice, white rats, rabbits and dogs, with indigo or cinnabar; 6 experiments were positive, 11 negative, the positive result occurring in cases where animals were subjected to rather physiologic conditions; the 11 negative ones, I should think, were due to a too severe restraint, whereby the animals were subjected to a pathologic condition. The experiments on animals under physiologic but precautionary measures are, in my opinion, only proving if positive, and not disproving if negative. The chief proof must lie in the human experiment. Hemmeter regards this Grützner antiperistaltic motion as only a very feeble marginal ascending movement, effected by surface contact of the particles with the epithelium, which in turn is moved by the muscularis serosa; further, he says, it is never visible to the eye, and it is not capable of propelling food masses. Among the abnormal conditions that may cause this visible antiperistalsis, Nothnagel mentions solution of sodium chlorid and introduction of food at an unphysiologic entry, which in man we must consider the rectum. Hemmeter differentiates between two antiperistaltic motions, Grützner's physiologic marginal invisible antiperistalsis and Nothnagel's pathologic visible one. I can not see the difference between Grützner's and Nothnagel's antiperistaltic motions, as Grützner did what Nothnagel stated as a cause of a visible antiperistalsis, namely, the introduction of food at an unphysiological point of entry.

---

*Presented to the Section on Physiology and Dietetics, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Hemmeter's opinion that food masses can not be propelled upward is not to be considered as entirely correct, as there are reports of undoubted propulsion of food masses. As early as 1827, Leslie reported a case of gastritis, in which on the fourth day an enema of turpentin and oil was rejected through the mouth; in 1857, Hall spoke on diaperistaltic and antiperistaltic action. Another case of antiperistalsis was reported by J. Frank, in 1883, where a nutrient enema was expelled by vomiting. Riegel joins Grützner and Swiezynski as to the positive result of the experiments and considers the antiperistaltic movements after injections into the rectum as proved.

As an antiperistalsis we have to regard the sensation of *globe hystérique*, and not so seldom nervous persons, especially women, complain of a sensation as if the bowels and stomach moved upward; it is true, as a rule, we consider these complaints as hysteric, i. e., often imaginary, while in other cases hysteric women tell us that they vomited excrements; even persons not nervous may tell the physician that they feel an upward motion in the intestines, which is followed by ructus.

The ruminating animals re-empty, physiologically, the contents of the rumen and reticulum into the mouth in order to swallow anew into the psalterium; pathologically we find regurgitation in certain cases of stomach disorders. Some of the animals of the lowest classes (celenteratæ) have the mouth and anus form one and the same opening, so that we have to assume that the excrements are propelled and evacuated by the same route through which food is ingested. Thus we learn by the way of comparative anatomy that antiperistaltic movements of the intestines are not impossible. In recent years a method of treatment of cholelithiasis consisted of oil enemas, and Blum observed that the oil migrates far up into the intestines till it comes in contact with the pancreatic juice, whereby the oil is saponified and thus becomes a cholagogue. In other cases of intestinal disorder, the same treatment with oil enemas has been used, and it is no doubt the covering of the mucous membrane rather than the possible absorption that has been said to have a curative effect; the same has been the case with enemas of solution of extract or infusion of whortleberries, of which I have seen good results in cases of enteritis.

In my above-mentioned experiments, for the injections I have used physiologic salt solutions, with additions of grape seeds, minute globules of tinfoil and kaolin granules, and regular nutritive enemas, to which I added dried whortleberries and oil with menthol. Grape seeds and whole whortleberries I thought suitable particles, because I knew that these pass the alimentary canal practically intact. I did not think the danger of possible inflammation of the vermiform process very great, because the foreign bodies are the last cause of appendicitis;[*] I should have liked to use the smallest aluminum globules, but not being able to obtain them, used the tinfoil. When using this it should be only such as is not adulterated with lead.

The experiments made are as follows:

Series 1.—To a healthy mulatto, 27 years old, the morning of April 14, 1898, after a movement of the bowels, three doses of calomel—3 grains each—in the course of three hours were given; two hours later, 1 table-spoonful of magnesium sulphate in ½ pint of warm water; during the afternoon there were six copious movements; no food of any kind was given, except water and whisky, and he had two evacuations during the night. On the following morning he received a cleansing soap and water enema, which was followed by two almost entirely watery evacuations; 1½ hours after this enema, 300 c.c. of a physiologic solution of sodium chlorid with the addition of twenty-five grape seeds were injected high up into the rectum—twenty inches—by a fountain syringe—Hegar's funnel, kept about 75 cm. above the body in the knee-elbow position; in order to have a very slow flow, I often compressed the tube; after injection, the mulatto had to take the left side position for one-half hour, and then he could take any position he liked; I thought he ought to be in the one a patient is supposed to assume when the nutritive enemas are administered. Soon he became rather hungry, as he had not taken any solid food for twenty-four hours. Five hours after the enema, I tried to introduce the stomach-tube, but he would not allow it: so at last I gave him a hypodermic injection of apomorphin and at the same time had him drink one-half pint of water with whisky; the effect was very prompt. He soon vomited a fluid of a slightly greenish-yellow color, which he said was very bitter, and in this three grape seeds were discovered. He then took a hearty meal of meat, potatoes, spinach and beer.

During the following days, I persuaded him to allow the introduction of the stomach-tube, and I performed the second experiment on April 19. In the morning of this day, I washed his stomach out as much as possible, again gave him three doses of calomel, 3 grains each, and then a solution of Epsom salts; he had several movements during the day, but no food except water, whisky and beer. The following morning an injection of soap and water was given and followed very soon by an evacuation; an hour later an enema of physiologic salt solution mixed with twenty-five minute globules of tinfoil; 5½ hours later, I introduced the stomach-tube, and poured 1 pint of a solution of bicarbonate of soda through it, with the intention of loosening particles in the stomach that might be too much attached to the gastric mucosa. Then I let the water off and by washing for a longer time—I used about a gallon of warm water—I recovered four globules of tinfoil.

The third experiment, a few days later, was made by the same method, again using globules of tinfoil, but I recovered only one.

In the fourth experiment I used physiological salt solution and globules of tinfoil, but could not find any of the latter afterward.

In the fifth experiment, globules of tinfoil in distilled water were used, but none found later.

In the sixth experiment, using globules of tinfoil in physiologic salt solution, three globules were found.

Series 2.—The next experiments were made on the black-and-tan dog. He was very much attached to me, and I had trained him several tricks, among them to "lie down and be dead," and he would lie on his back with outstretched legs for many minutes without moving. The dog hungered for twenty-four hours. I put a cloth-covered muzzle around his head and injected 100-150 c.c. of salt solution with the addition of grape seeds, globules of tinfoil, little granules of kaolin and Arminian bole into the rectum. I did not wish to kill the animal and so resorted to the hypodermic use of apomorphin. The before-mentioned mulatto willingly aided me in experimenting on the dog, which I tied very short. Seven experiments were made on this animal. Of 5 made with physiologic salt solution 4 proved positive, 1 negative. The sixth and seventh with distilled water, *were negative*.

---

[*] We have all heard of cherry stones, grape seeds, and many similar foreign bodies finding lodgment in the appendix vermiformis, but these are all foreign immigrants into the United States of Anatomy (N. Y. Med. Jour., May 26, 1900). Dr. J. Bauer says (Aerztlicher Verein in Munchen, Jan. 17, 1900, *Deutsche Med. Woch.*, May 10, 1900, *Vereinsbeilage* No. 18, p. 110): In connection with catarrh of the vermiform process fecal concretions may be formed; foreign bodies in the appendix do not exist; the fecal concretions may cause ulceration. Dr. O. Bollinger says (ibid.): The foreign bodies in the vermiform process are always fecal concretions. The vermiform process in the dog, very like that in man, is never diseased, though the dog swallows many foreign bodies.

Series 3.—I made the third series of experiments in August and September, 1899, in the course of treatment of a woman suffering from mechanical insufficiency of the stomach with a subacid condition (*total acidity: Phenolphthalein*, 24; HCl, .04 per cent., Toepfer). I excluded any food or drink by the mouth, and nutritive enemas were administered for eleven succeeding days; the result of the treatment was everything *that could* be wished for. The first enemas—all given in the knee-elbow position—were evacuated very soon, undoubtedly on account of the nervous condition of the patient. But from the third day on the remainder of *the enemas* were *not* expelled before *five* or six hours had passed; frequently no movement of the bowels followed from the evening to the morning. The quantity of the enema was 250 to 300 c.c. in general three times a day, in intervals of six to seven hours. The woman had been treated by lavage before she came under my treatment and was well used to the stomach tube. The *enema itself consisted* of a mixture of 250 c.c. of milk and cream, 2 eggs, 1 tablespoonful of a mixture of tropon and cornstarch and a pinch of sodium chlorid, and was brought up 15 to 22 inches into the rectum. A part of the treatment was also the injection of cottonseed-oil—250 c.c.—emulsified with oleic acid or rather sodium oleate (eunatrol). Several times, a few hours after the *injection of the enemas the patient complained of eructations* and a sensation of tasting eggs, other times tasting of grease or oil. These complaints induced me to start the experiment, the experimental additions being without the knowledge of the patient. To the nutriment enemas I added small, dried, uncooked whortleberries, which I knew would as a rule pass the alimentary canal quite unaffected by the digestive juices of the intestines. Four experiments were made *and*, by means of the stomach-tube, through which I introduced 1 quart of water, I twice recovered whortleberries; the other *two times I could not* discover any. Two experiments were made with oil emulsion, to which menthol—validol—was added. One time the patient noted a marked peppermint *flavor*, and both times *I recovered*, during *lavage* of the stomach, about 10 c.c. of the emulsified oil with a marked flavor of menthol. The stomach lavage occurred between five or six hours after the injection of the enema.

Reviewing the series of experiments, we find: One spontaneous experiment on a patient, 6 experiments on the mulatto, 7 experiments on the dog, 6 experiments on the woman patient—a total of 20. Of these 3 made with oil and 10 made with NaCl solution proved positive; 4 made with the latter solution proved negative, as far as the stomach is concerned, while 3 made with distilled water also proved negative.

The result of my experiments may be put down as positive in the meaning of Grützner, Swiezynski and Riegel. In this matter we can better understand the good effect of the nutritive enemas, especially when we consider cases in which patients have been nourished exclusively by rectal feeding, not only for days or weeks —among others, Donkin, up to 23 days; Boas, up to 14 days; D. D. Stewart, 23 days; the writer, 11 days—but also for months—Leube 6, and Riegel 10 months. The occasions of temporarily suspending the ingestion of food into the stomach are not too rare, particularly in cases of stenosis of the esophagus, cardia and pylorus, gastric ulceration and hemorrhage, certain poisonings, when the mucous membranes are destroyed, gastric hyper-irritation and dilatation of the stomach; besides these, rectal injections can be effectively used as carriers of medicine in cases of intestinal affections.

In conclusion, I should like to suggest to my colleagues that they make further experiments along this line, so that no doubt will prevail whether *antiperistalsis* is the rule or the exception.

THE ETIOLOGY OF YELLOW FEVER.

AN ADDITIONAL NOTE.*

WALTER REED, M.D.,
SURGEON, UNITED STATES ARMY.
JAS. CARROLL, M.D., AND ARISTIDES AGRAMONTE, M.D.,
ACTING ASSISTANT-SURGEONS, U. S. ARMY.

At the Twenty-eighth Annual Meeting of the American Public Health Association,[1] held in Indianapolis, Ind., Oct. 22-26, 1900, we presented, in the form of a preliminary note, the results of our bacteriologic study of yellow fever, based on cultures taken from the blood in eighteen cases, at various stages of the disease, as well as on those which we had made from the blood and organs of eleven yellow fever cadavers. We also recorded the results obtained from the inoculation of eleven non-immune individuals by means of the bite of mosquitoes (culex fasciatus, Fabr.) that had previously fed on the blood of patients sick with yellow fever. We were able to report two positive results, in which the attack of yellow fever followed the bite of a mosquito within the usual period of incubation of this disease.

In one of these cases all other sources of infection could be positively excluded. From our several observations we drew the following conclusions: 1. Bacillus icteroides (Sanarelli) stands in no causative relation to yellow fever, but, when present, should be considered as a secondary invader in this disease. 2. The mosquito serves as the intermediate host for the parasite of yellow fever.

capable of propelling food masses. Among the abnormal conditions that may cause this visible antiperistalsis, Nothnagel mentions solution of sodium chlorid and introduction of food at an unphysiologic entry, which in man we must consider the rectum. Hemmeter differentiates between two antiperistaltic motions, Grützner's physiologic marginal invisible antiperistalsis and Nothnagel's pathologic visible one. I can not see the difference between Grützner's and Nothnagel's antiperistaltic motions, as Grützner did what Nothnagel stated as a cause of a visible antiperistalsis, namely, the introduction of food at an unphysiological point of entry.

Hemmeter's opinion that food masses can not be propelled upward is not to be considered as entirely correct, as there are reports of undoubted propulsion of food masses. As early as 1827, Leslie reported a case of gastritis, in which on the fourth day an enema of turpentin and oil was rejected through the mouth; in 1857, Hall spoke on diaperistaltic and antiperistaltic action. Another case of antiperistalsis was reported by J. Frank, in 1883, where a nutrient enema was expelled by vomiting. Riegel joins Grützner and Swiezynski as to the positive result of the experiments and considers the antiperistaltic movements after injections into the rectum as proved.

As an antiperistalsis we have to regard the sensation of *globe hystérique*, and not so seldom nervous persons, especially women, complain of a sensation as if the bowels and stomach moved upward; it is true, as a rule, we consider these complaints as hysteric, i. e., often imaginary, while in other cases hysteric women tell us that they vomited excrements; even persons not nervous may tell the physician that they feel an upward motion in the intestines, which is followed by ructus.

The ruminating animals re-empty, physiologically, the contents of the rumen and reticulum into the mouth in order to swallow anew into the psalterium; pathologically we find regurgitation in certain cases of stomach disorders. Some of the animals of the lowest classes (celenteratæ) have the mouth and anus form one and the same opening, so that we have to assume that the excrements are propelled and evacuated by the same route through which food is ingested. Thus we learn by the way of comparative anatomy that antiperistaltic movements of the intestines are not impossible. In recent years a method of treatment of cholelithiasis consisted of oil enemas, and Blum observed that the oil migrates far up into the intestines till it comes in contact with the pancreatic juice, whereby the oil is saponified and thus becomes a cholagogue. In other cases of intestinal disorder, the same treatment with oil enemas has been used, and it is no doubt the covering of the mucous membrane rather than the possible absorption that has been said to have a curative effect; the same has been the case with enemas of solution of extract or infusion of whortleberries, of which I have seen good results in cases of enteritis.

In my above-mentioned experiments, for the injections I have used physiologic salt solutions, with additions of grape seeds, minute globules of tinfoil and kaolin granules, and regular nutritive enemas, to which I added dried whortleberries and oil with menthol. Grape seeds and whole whortleberries I thought suitable particles, because I knew that these pass the alimentary canal practically intact. I did not think the danger of possible inflammation of the vermiform process very great, because the foreign bodies are the last cause of appendicitis;* I should have liked to use the smallest aluminum globules, but not being able to obtain them, used the tinfoil. When using this it should be only such as is not adulterated with lead.

The experiments made are as follows:

Series 1.—To a healthy mulatto, 27 years old, the morning of April 14, 1898, after a movement of the bowels, three doses of calomel—3 grains each—in the course of three hours were given; two hours later, 1 table-spoonful of magnesium sulphate in ½ pint of warm water; during the afternoon there were six copious movements; no food of any kind was given, except water and whisky, and he had two evacuations during the night. On the following morning he received a cleansing soap and water enema, which was followed by two almost entirely watery evacuations; 1½ hours after this enema, 300 c.c. of a physiologic solution of sodium chlorid with the addition of twenty-five grape seeds were injected high up into the rectum—twenty inches—by a fountain syringe—Hegar's funnel, kept about 75 cm. above the body in the knee-elbow position; in order to have a very slow flow, I often compressed the tube; after injection, the mulatto had to take the left side position for one-half hour, and then he could take any position he liked; I thought he ought to be in the one a patient is supposed to assume when the nutritive enemas are administered. Soon he became rather hungry, as he had not taken any solid food for twenty-four hours. Five hours after the enema, I tried to introduce the stomach-tube, but he would not allow it; so at last I gave him a hypodermic injection of apomorphin and at the same time had him drink one-half pint of water with whisky; the effect was very prompt. He soon vomited a fluid of a slightly greenish-yellow color, which he said was very bitter. and in this three grape seeds were discovered. He then took a hearty meal of meat, potatoes, spinach and beer.

During the following days. I persuaded him to allow the introduction of the stomach-tube, and I performed the second experiment on April 19. In the morning of this day, I washed his stomach out as much as possible, again gave him three doses of calomel, 3 grains each, and then a solution of Epsom salts; he had several movements during the day, but no food except water, whisky and beer. The following morning an injection of soap and water was given and followed very soon by an evacuation; an hour later an enema of physiologic salt solution mixed with twenty-five minute globules of tinfoil; 5½ hours later, I introduced the stomach-tube, and poured 1 pint of a solution of bicarbonate of soda through it, with the intention of loosening particles in the stomach that might be too much attached to the gastric mucosa. Then I let the water off and by washing for a longer time—I used about a gallon of warm water—I recovered four globules of tinfoil.

The third experiment, a few days later. was made by the same method, again using globules of tinfoil. but I recovered only one.

In the fourth experiment I used physiological salt solution and globules of tinfoil, but could not find any of the latter afterward.

In the fifth experiment, globules of tinfoil in distilled water were used, but none found later.

In the sixth experiment, using globules of tinfoil in physiologic salt solution, three globules were found.

Series 2.—The next experiments were made on the black-and-tan dog. He was very much attached to me, and I had trained him several tricks, among them to "lie down and be dead," and he would lie on his back with outstretched legs for many minutes without moving. The dog hungered for twenty-four hours. I put a cloth-covered muzzle around his head and injected 100-150 c.c. of salt solution with the addition of grape seeds, globules of tinfoil, little granules of kaolin and Arminian bole into the rectum. I did not wish to kill the animal and so resorted to the hypodermic use of apomorphin. The before-mentioned mulatto willingly aided me in experimenting on the dog, which I tied very short. Seven experiments were made on this animal. Of 5 made with physiologic salt solution 4 proved positive, 1 negative. The sixth and seventh with distilled water, were negative.

---

* We have all heard of cherry stones, grape seeds, and many similar foreign bodies finding lodgment in the appendix vermiformis, but these are all foreign immigrants into the United States of Anatomy (N. Y. Med. Jour., May 26, 1900). Dr. J. Bauer says (Aerztlicher Verein in Munchen. Jan. 17, 1900, *Deutsche Med. Woch.*, May 10, 1900. *Vereinsbeilage No. 18, p. 116*): *In connection with catarrh of the vermiform process fecal concretions may be formed; foreign bodies in the appendix do not exist; the fecal concretions may cause ulceration.* Dr. O. Bollinger says (ibid.): The foreign bodies in the vermiform process are always fecal concretions. The vermiform process in the dog, very like that in man, is never diseased, though the dog swallows many foreign bodies.

Series 3.—I made the third series of experiments in August and September, 1899, in the course of treatment of a woman suffering from mechanical insufficiency of the stomach with a subacid condition (total acidity: Phenolphthalein, 24; HCl, .04 per cent., Toepfer). I excluded any food or drink by the mouth, and nutritive enemas were administered for eleven succeeding days; the result of the treatment was everything that could be wished for. The first enemas—all given in the knee-elbow position—were evacuated very soon, undoubtedly on account of the nervous condition of the patient. But from the third day on the remainder of the enemas were not expelled before five or six hours had passed; frequently no movement of the bowels followed from the evening to the morning. The quantity of the enema was 250 to 300 c.c. in general three times a day, in intervals of six to seven hours. The woman had been treated by lavage before she came under my treatment and was well used to the stomach tube. The enema itself consisted of a mixture of 250 c.c. of milk and cream, 2 eggs, 1 tablespoonful of a mixture of tropon and cornstarch and a pinch of sodium chlorid, and was brought up 15 to 22 inches into the rectum. A part of the treatment was also the injection of cottonseed-oil—250 c.c.—emulsified with oleic acid or rather sodium oleate (eunatrol). Several times, a few hours after the injection of the enemas the patient complained of eructations and a sensation of tasting eggs, other times tasting of grease or oil. These complaints induced me to start the experiment, the experimental additions being without the knowledge of the patient. To the nutriment enemas I added small, dried, uncooked whortleberries, which I knew would as a rule pass the alimentary canal quite unaffected by the digestive juices of the intestines. Four experiments were made and, by means of the stomach-tube, through which I introduced 1 quart of water, I twice recovered whortleberries; the other two times I could not discover any. Two experiments were made with oil emulsion, to which menthol—validol—was added. One time the patient noted a marked peppermint flavor, and both times I recovered, during lavage of the stomach, about 10 c.c. of the emulsified oil with a marked flavor of menthol. The stomach lavage occurred between five or six hours after the injection of the enema.

Reviewing the series of experiments, we find: One spontaneous experiment on a patient, 6 experiments on the mulatto, 7 experiments on the dog, 6 experiments on the woman patient—a total of 20. Of these 3 made with oil and 10 made with NaCl solution proved positive; 4 made with the latter solution proved negative, as far as the stomach is concerned, while 3 made with distilled water also proved negative.

The result of my experiments may be put down as positive in the meaning of Grützner, Swiezynski and Riegel. In this matter we can better understand the good effect of the nutritive enemas, especially when we consider cases in which patients have been nourished exclusively by rectal feeding, not only for days or weeks—among others, Donkin, up to 23 days; Boas, up to 14 days; D. D. Stewart, 23 days; the writer, 11 days—but also for months—Leube 6, and Riegel 10 months. The occasions of temporarily suspending the ingestion of food into the stomach are not too rare, particularly in cases of stenosis of the esophagus, cardia and pylorus, gastric ulceration and hemorrhage, certain poisonings, when the mucous membranes are destroyed, gastric hyper-irritation and dilatation of the stomach; besides these, rectal injections can be effectively used as carriers of medicine in cases of intestinal affections.

In conclusion, I should like to suggest to my colleagues that they make further experiments along this line, so that no doubt will prevail whether antiperistalsis is the rule or the exception.

[1] Phila. Med. Jour., Oct. 27, 1900.

Since the publication of our preliminary note, we have continued our investigations, especially as regards the means by which yellow fever is propagated from individual to individual, and as to the manner in which houses become infected with the contagium of this disease. The results already obtained are so positive and striking that, with the permission of Surgeon-General Sternberg, we have concluded to present to this Congress an additional note, in which we will record these later observations. We desire to here express our sincere thanks to the Military Governor of the Island of Cuba, Major General Leonard Wood, U. S. V., without whose approval and assistance these observations could not have been carried out.

In order to exercise perfect control over the movements of those individuals who were to be subjected to experimentation, and to avoid any other possible source of infection, a location was selected in an open and uncultivated field, about one mile from the town of Quemados, Cuba. Here an experimental sanitary station was established under the complete control of the senior member of this Board. This station was named Camp Lazear, in honor of our late colleague, Dr. Jesse W. Lazear, Acting Assistant-Surgeon, U. S. A., who died of yellow fever, while courageously investigating the causation of this disease. The site selected was very well drained, freely exposed to sunlight and winds, and, from every point of view, satisfactory for the purposes intended.

The personnel of this camp consisted of two medical officers, Dr. Roger P. Ames, Acting Assistant-Surgeon, U. S. A., an immune, in immediate charge; Dr. R. P. Cooke, Acting Assistant-Surgeon, U. S. A., non-immune; one acting hospital steward, an immune; nine privates of the hospital corps, one of whom was immune, and one immune ambulance driver.

For the quartering of this detachment, and of such non-immune individuals as should be received for experimentation, hospital tents, properly floored, were provided. These were placed at a distance of about twenty feet from each other, and were numbered 1 to 7 respectively.

Camp Lazear was established Nov. 20, 1900, and from this date was strictly quarantined, no one being permitted to leave or enter camp except the three immune members of the detachment and the members of the Board. Supplies were drawn chiefly from Columbia Barracks, and for this purpose a conveyance under the control of an immune acting hospital steward, and having an immune driver, was used.

A few Spanish immigrants recently arrived at the Port of Havana, were received at Camp Lazear, from time to time, while these observations were being carried out. A non-immune person, having once left this camp, was not permitted to return to it under any circumstances whatever.

The temperature and pulse of all non-immune residents were carefully recorded three times a day. Under these circumstances any infected individual entering the camp could be promptly detected and removed. As a matter of fact only two persons, not the subject of experimentation, developed any rise of temperature; one, a Spanish immigrant, with probably commencing pulmonary tuberculosis, who was discharged at the end of three days; and the other, a Spanish immigrant, who developed a temperature of 102.6 F. on the afternoon of his fourth day in camp. He was at once removed with his entire bedding and baggage and placed in the receiving ward at Columbia Barracks. His fever, which was marked by daily intermissions for three days, subsided upon the administration of cathartics and enemata. His attack was considered to be due to intestinal irritation. He was not permitted, however, to return to the camp.

No non-immune resident was subjected to inoculation who had not passed in this camp the full period of incubation of yellow fever, with one exception, to be hereinafter mentioned.

OBSERVATIONS.

Having thus sufficiently indicated the environment of Camp Lazear and the conditions under which its residents lived, we will now proceed to a narration of the observations thus far made at this experimental station. At the time these inoculations were begun, the several tents were occupied as follows: Tent No. 1 by 1 immune and 1 non-immune; No. 2 by 1 immune and 2 non-immunes; No. 3 by 2 immunes; No. 4 by 3 non-immunes; No. 5 by 3 non-immunes; No. 6 by 2 non-immunes; and No. 7 by 1 non-immune.

For the purpose of experimentation subjects were selected as follows: from Tent No. 2, 2 non-immunes, and from Tent No. 5, 3 non-immunes. Later, 1 non-immune in Tent No. 6 was also designated for inoculation.

Case 1.—Private John R. Kissinger, Hospital Corps, U. S. A., aged 23, a non-immune, occupant of Tent No. 2, with his full consent, was bitten at 10.30 a. m., Nov. 20, 1900, by a mosquito —C. fasciatus—that had bitten a severe case of yellow fever on the fifth day, eleven days previously; another severe case, on the third day, six days before, and a third severe one on the third day, three days before. As Kissinger had not absented himself from Columbia Barracks for a period of more than thirty days, it was considered safe to inoculate him without waiting for his period of incubation to pass.

Nov. 23, 1900, Kissinger was again bitten by the same mosquito. The result of both inoculations was negative. The mosquito, therefore, was incapable of conveying any infection on the eleventh or fourteenth day after it had bitten a severe case of yellow fever on the third day of the disease. This insect had been kept at ordinary room temperature and died November 26, 1900.

Dec. 5, 1900, at 2 p. m., twelve days after the last inoculation, Kissinger was again bitten by five mosquitoes—C. fasciatus—two of which had bitten fatal cases of yellow fever, on the second day, fifteen days before; one a severe case on the second day, nineteen days previously, and two a mild case on the third day, twenty-one days before.

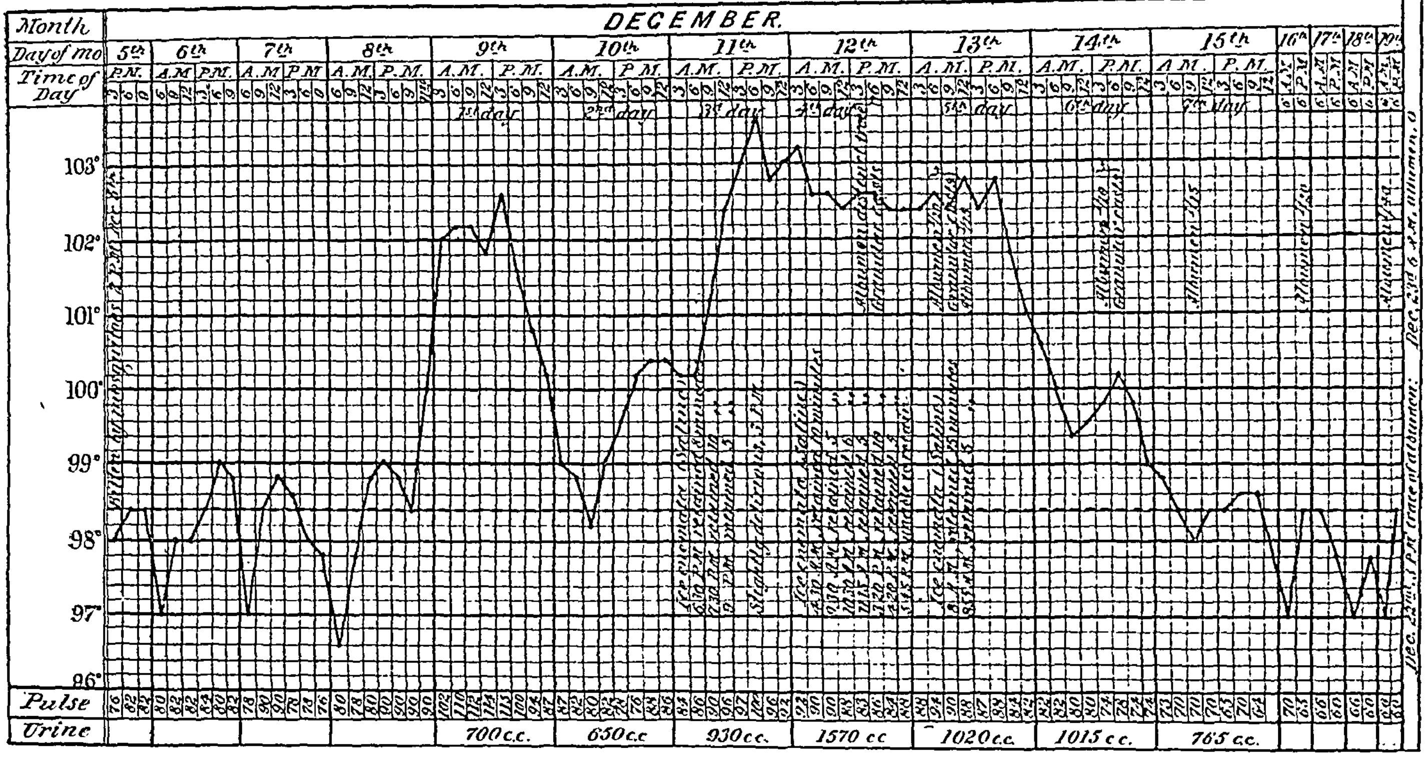
The record of temperature and pulse, taken every three hours, following this inoculation, showed that the subject remained in his usual state of health during the following three days, except that on December 8, on the third day, Kissinger had slight vertigo, upon rising, which soon passed away. At 4.30 p. m.—commencement of fourth day—he complained of frontal headache; otherwise he felt well and partook of supper with appetite; at 9 p.m., temperature was 98.4 F., pulse 90; at 11.30 p. m., he awoke with a chill, his temperature 100 F., pulse 90; he complained of severe frontal headache and backache; his eyes were injected and his face suffused. December 9 at 3 a. m., his temperature was 102 F., pulse 102; he had violent headache and backache with nausea and vomiting. He was then removed to the yellow fever wards. His subsequent history was that of a case of yellow fever at moderate severity. Albumin appeared in the urine on the fourth day, increased to one-fifth by volume on the sixth day and disappeared on December 22. Granular casts were present in considerable numbers from the fourth to the eighth day. The conjunctivæ were jaundiced on the third day. The diagnosis of yellow fever in this case was made by Drs. Juan Guitéras, Carlos Finlay, W. C. Gorgas, and A. Diaz Albertini, the board of yellow fever experts of the city of Havana, who saw the patient on several occasions during his illness. (See Chart I.) The period of incubation in this case was 3 days, 9½ hours.

Case 2.—John J. Moran, aged 24, an American, non-immune occupant of Tent No. 2, with his full consent, was bitten at 10 a. m., Nov. 26, 1900, by a mosquito—C. fasciatus—which twelve days before had bitten a case of yellow fever of moderate severity, on the third day of the disease. This insect had also bitten a well-marked case of yellow fever—second day—ten days previously.

Yellow fever, produced by the bite of Culex fasciatus

Chart I.

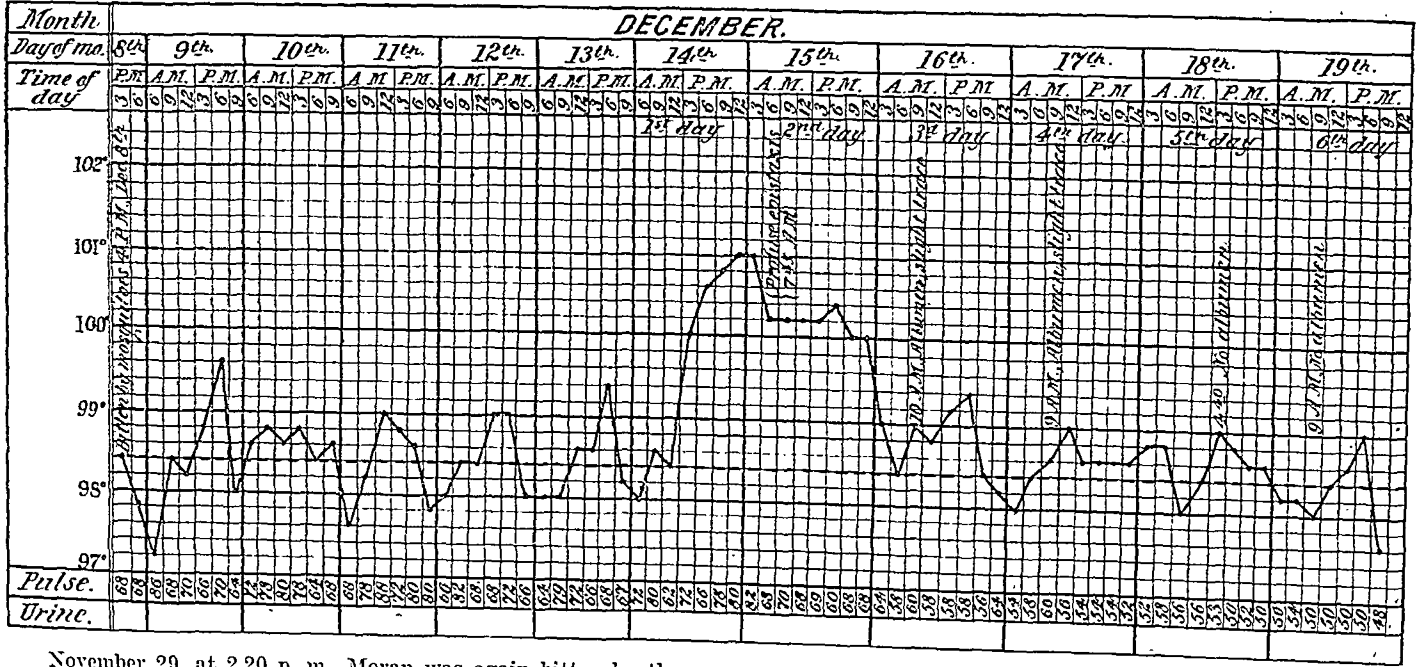
Period of incubation, 3 days 9½ hours.



Yellow fever, produced by the bite of Culex fasciatus.

Chart II.

Period of incubation, 4 days 20 hours.



November 29, at 2.20 p. m., Moran was again bitten by the same mosquito. The result of both of these inoculations was negative. This insect was, therefore, incapable of conveying the infection fifteen days after having bitten a case of yellow fever of moderate severity on the third day, and thirteen days after it had bitten a well-marked case of this disease on the second day. This mosquito had been kept at room temperature. Moran's case will be again referred to when we come to speak of the infection of a building by means of contaminated mosquitoes.

Case 3.—A Spanish immigrant, aged 26, a non-immune occupant of Tent No. 5, with his full consent, was bitten at 4 p. m., Dec. 8, 1900, by four mosquitoes—C. fasciatus—which had been contaminated as follows: one by biting a fatal case of yellow fever, on the third day, seventeen days before; one a severe one, on the third day, eighteen days before; one a severe case, on the second day, twenty-two days before, and one a case of moderate severity, on the third day, twenty-four days previously.

The record of temperature and pulse, taken every three hours after the inoculation, shows no rise of temperature above 99 F. until 6 p. m., December 13, on the sixth day, when 99.4 F. is recorded; pulse 68. The subject, who was of a very lively disposition, retained his usual spirits until noon of the 13th, although he complained of slight frontal headache on the 11th and 12th. He took to his bed at noon of the 13th, the fifth day, complaining of increased frontal headache and a sense of fatigue. At 9 p. m., his temperature was 98.2 F., pulse 62.

December 14, at 6 a. m., temperature was 98 F., pulse 72, and he still complained of frontal headache and general malaise. Profuse epistaxis occurred at 7.45 a. m.; at 9 a. m., temperature was 99.6 F., pulse 80; at 1.15 p. m., temperature was 100 F., pulse 80, and he complained of a sense of chilliness, with frontal headache increased, and slight pain in the back, arms and legs; at 3 p. m., temperature was 100 F., pulse 80; at 4.15 p. m., temperature 100.7 F., pulse 68; his face flushed and eyes congested. He was removed to the yellow fever wards. A trace of albumin was found in the urine passed at 3.30 p. m., December 15; a few hyaline cases were present. He was seen at this time by the Havana board of experts and the diagnosis of mild yellow fever confirmed. (See Chart No. 2.)

The period of incubation in this case was four days and twenty fours, counting from the time of inoculation to the hour when the patient took to his bed; if reckoned to the onset of fever, it was 5 days and 17 hours.

Case 4.—A Spanish immigrant, aged 27, a non-immune occupant of Tent No. 5, with his full consent, was bitten at 10 a.m., Nov. 26, 1900, by a mosquito—C. fasciatus—which had bitten a severe case of yellow fever, on the second day, ten days before. Three days later, November 29, he was again bitten by the same insect. December 2, after an interval of three days, he was again bitten by the same insect, and also by a second mosquito—C. fasciatus—which, twelve days before, had been contaminated by biting a fatal case of yellow fever on the third day. No unfavorable effects followed any of these attempted inoculations. The first-mentioned mosquito, therefore, was incapable of conveying any infection on the seventeenth day after biting a severe case of yellow fever on the second day; the other also failed to infect on the twelfth day after biting a fatal case of yellow fever on the third day. Both of these mosquitoes had been kept at ordinary room temperature.

December 9, after an interval of seven days, the subject was again bitten, at 10.30 a. m., by one mosquito—C. fasciatus—which had been infected nineteen days before by biting a fatal case of yellow fever on the second day of the disease. He remained in his usual health until 9 a.m., December 12, the third day, when he complained of frontal headache; his temperature was 98.8 F., pulse 96. This headache continued during the entire day. At 6 p.m., temperature was 99 F., pulse 94; at 9 p. m., temperature 99 F., pulse 84; at 9.30 p. m., temperature 99.4 F., pulse 82. Severe headache and backache was complained of; his eyes were injected and his face suffused. The following morning he was sent to the yellow fever wards. Urine passed at 4.20 p. m., December 15, the third day, gave a distinct trace of albumin. Many hyaline casts were present on the same date. The conjunctivæ were jaundiced on the third day.

The patient was seen by the board of experts on December 14, and the diagnosis of yellow fever made. (See Chart No. 3.)

The period of incubation in this case was 3 days, 11½ hours.

Case 5.—A Spanish immigrant, aged 26, a non-immune occupant of Tent No. 5, with his full consent, was bitten at 10 a.m., Nov. 26, 1900, by a mosquito—C. fasciatus—that had bitten a well-marked case of yellow fever, on the third day, twelve days before. November 29 he was again bitten by the same insect. December 2 he was for the third time bitten by two mosquitoes—C. fasciatus—both of which had bitten a well-marked case of yellow fever, on the third day, eighteen days before. As no bad results followed any of these inoculations, it follows that these mosquitoes were incapable of conveying any infection eighteen days after they had bitten a well-marked case of yellow fever on the third day. Both of these insects had been kept at room temperature.

December 11, after an interval of nine days, the subject was again, at 4:30 p.m., bitten by the same mosquitoes, four in number, that had been applied to Case 3, three days prior to this time, with positive results.

The record of temperature and pulse, taken every three hours following the inoculation, showed no change till December 13, the second day, at 9 a.m., when the temperature was 99 F., and the pulse 78. From this hour till 6 p.m. the temperature varied from 99.2 to 99.6 F. The subject complained of frontal headache, slight in degree, during the entire day. At 9 p.m. his temperature was 98.4 F., pulse 62.

December 14, the third day, he complained of slight frontal headache during the entire day, and was indisposed to exertion. From 6 a.m. to 6 p.m. the temperature averaged 99.2 F., and the pulse varied from 64 to 90; at 9 p.m. it was 98.4 F., the pulse 78. December 15, the fourth day, at 6 a.m., temperature was 98.2 F., pulse 78. He still had frontal headache. At 9 a.m., temperature was 99.2 F., pulse 80; at 12, noon, the former was 99.2 F., the pulse 74. The subject now went to bed, complaining of headache and pains throughout the body. At 2 p.m., the temperature was 100 F., the pulse 80; eyes much congested; face flushed. At 6 p.m. his temperature had risen to 102 F., and the pulse to 90. He was then transferred to the yellow fever wards. Albumin appeared in the urine at 7:30 a.m., December 17. Bleeding from the gums and roof of the mouth occurred on the sixth and seventh days of his illness.

This case was examined by the board of experts on the 16th and 19th, and the diagnosis of yellow fever made.

Albumin disappeared on the sixth day, the temperature falling to normal on this date, and remaining near this point till December 23, the ninth day of sickness, when a relapse occurred, attended with bleeding from the gums on December 24 and 25, with the appearance of red blood cells and pus cells in the urine in moderate numbers. Fever subsided on December 26, and the urine became normal on December 29. (See Chart iv.)

The period of incubation in this case, if reckoned from the time of inoculation to the hour when the patient took to his bed, was 3 days, 19½ hours.

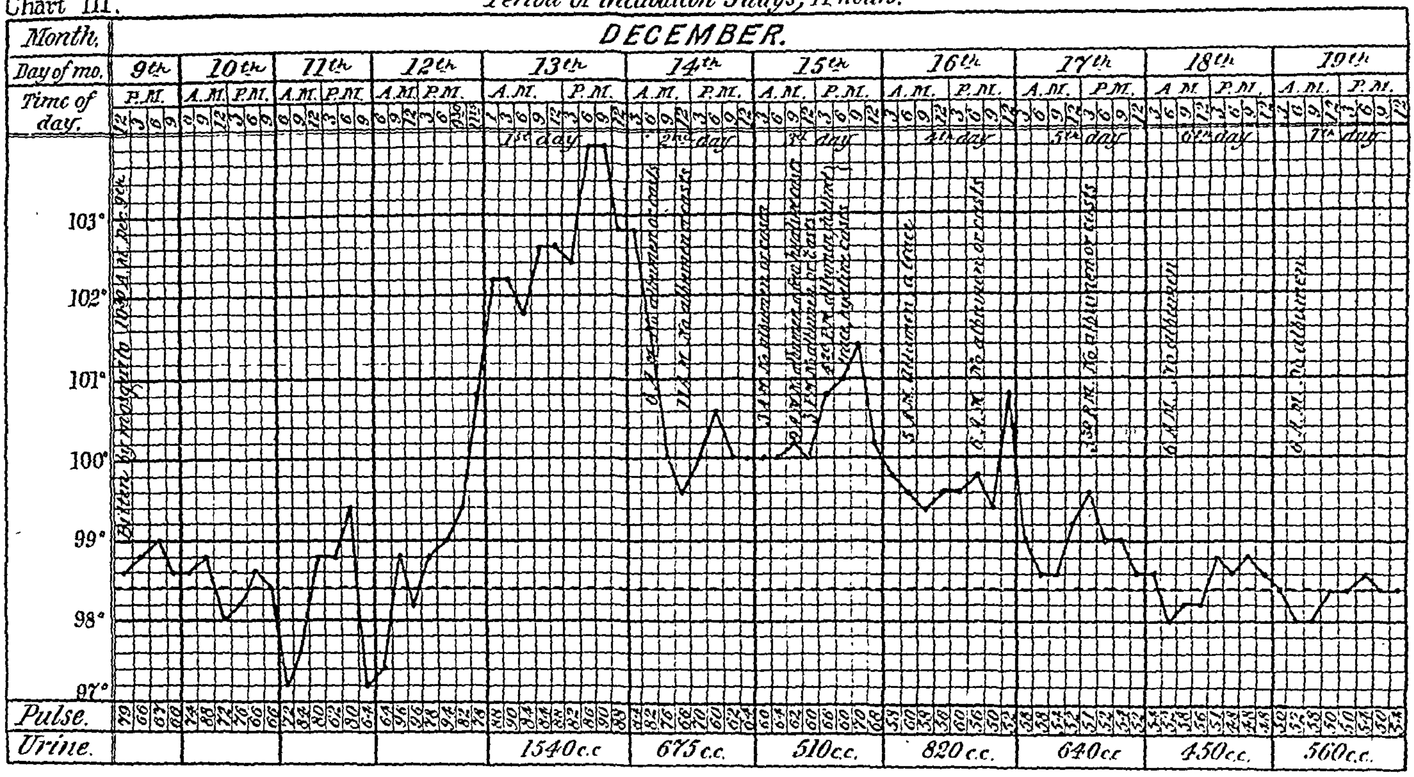
The four patients whose histories we have given above were also examined by a number of physicians of Havana, among whom we may mention Dr. Bango, of "La Covadonga," Dr. Sanchez, of "La Benéfica," and Dr. Moas, of "La Purissima Concepcion," by all of whom the diagnosis of yellow fever was confirmed. Let us now rapidly review the circumstances attending these cases of experimental yellow fever, in order to emphasize certain points of interest and importance in connection with their occurrence. (We omit any reference to the clinical histories.)

It should be borne in mind that at the time when these inoculations were begun, there were only 12 non-immune residents at Camp Lazear, and that 5 of these were selected for experiment, viz., 2 in Tent No. 2, and 3 in Tent No. 5. Of these we succeeded in infecting 4, viz., 1 in Tent No. 2 and 3 in Tent No. 5, each of whom developed an attack of yellow fever within the period of incubation of this disease. The one negative result, therefore, was in Case 2—Moran—inoculated with a mosquito on the fifteenth day after the insect had bitten a case of yellow fever on the third day. Since this mosquito failed to infect Case 4, three days after it had bitten Moran, it follows that the result could not have been otherwise than negative in the latter case. We now know, as the result of our observations, that in the case of an insect kept at room temperature during the cool weather of November, fifteen or even eighteen days would, in all probability, be too short a time to render it capable of producing the disease.

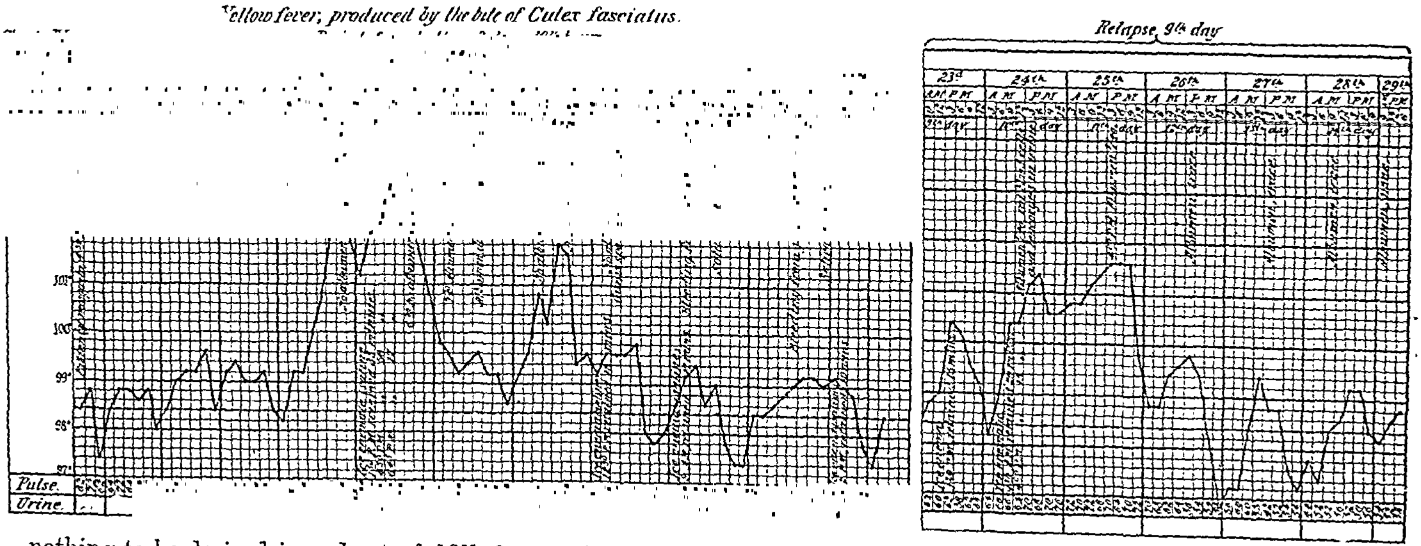
As bearing upon the source of infection, we invite attention to the period of time during which the subjects had been kept under rigid quarantine, prior to successful inoculation, which was as follows: Case 1, fifteen days; Case 3, nine days; Case 4, nineteen days; Case 5, twenty-one days. We further desire to emphasize the fact that this epidemic of yellow fever, which affected 33.33 per cent. of the non-immune residents of Camp Lazear, did not concern the 7 non-immunes occupying Tents No. 1, 4, 6 and 7, *but was strictly limited to those individuals who had been bitten by contaminated mosquitoes.*

Yellow fever produced by the bite of Culex fasciatus.

Chart III. *Period of incubation 3 days, 11 hours.*



Yellow fever, produced by the bite of Culex fasciatus.



Nothing could point more forcibly to the source of this infection than the order of the occurrence of events at this camp. The precision with which the infection of the individual followed the bite of the mosquito left nothing to be desired in order to fulfill the requirements of a scientific experiment.

The epidemic having ceased on Dec. 15, 1900, no other case of yellow fever occurred in this camp until we again began to expose individuals to inoculation. Thus fifteen days later we made the following observation:

Case 6.—A Spanish immigrant, aged 27, a non-immune occupant of Tent No. 6, with his full consent, was bitten at 11 a.m., Dec. 30, 1900, by four mosquitoes—C. fasciatus—that had been contaminated seventeen days previously by biting a mild case of yellow fever on the first day of the disease (Case 4). These insects had been kept at a temperature of 82 F.

The subject remained in his normal condition until the evening of Jan. 2, 1901, the third day, when he complained of frontal headache. At 6 p.m., his temperature was 99 F., pulse 64. He slept well, but still complained of headache on the following morning, January 3. He partook sparingly of breakfast, and afterward lay on his bed, being disinclined to exert himself. At 9 a.m., the temperature was 99 F., the pulse 96; at 10:30 a.m., temperature 100 F., pulse 80. A sense of chilliness and sharp frontal headache was complained of, and at 3 p.m. his temperature was 100.8 F., his pulse 89, and his eyes were congested and face flushed. He was removed to the yellow fever wards. A specimen of urine passed at midnight, January 4, contained a distinct trace of albumin. Slight bleeding from the gums occurred on the fifth and sixth days. The patient was seen by the board of experts on the second and seventh days of his attack, and the diagnosis of yellow fever confirmed. (See Chart v.)

The period of incubation in this case was three days, 22½ hours. The subject had remained in strict quarantine for twenty-two days preceding his inoculation.

In considering the character of the attacks and the course of the disease in these five cases of experimental yellow fever, it must be borne in mind that these infected individuals were all young men, in good general physical condition and placed amid excellent hygienic surroundings. Further, it must not be forgotten that, upon the earliest manifestation of an approaching infection, they were each and all put to bed at once, and were even carried to the yellow fever wards while occupying the same bed. In other words, these men were kept at absolute rest from the first inception of the disease. Just what bearing this may have had on the subsequent course of the fever, we can not say, but since so much stress is laid on absolute rest of the patient by those having most experience in the treatment of yellow fever, the influence of this enforced rest, in our cases, upon the subsequent course of the attack, was doubtless of much importance. We reserve a consideration of the clinical side of these cases for a future report.

In our opinion the experiments above described conclusively demonstrate that an attack of yellow fever may be readily induced in the healthy subject by the bite of mosquitoes—C. fasciatus—which have been previously contaminated by being fed with the blood of those sick with yellow fever, provided the insects are kept for a sufficient length of time after contamination before being applied to the person to be infected.

Our observations do not confirm Finlay's statement that the bite of the mosquito may confer an abortive attack of yellow fever, when applied to the healthy subject two to six days after it has bitten a yellow fever patient. We have always failed to induce an attack, even of the mildest description, when we have used mosquitoes within less than twelve days from the time of contamination, although the insects were constantly kept at summer temperature. We could cite instances where we have applied mosquitoes at intervals of two, three, four, five, six, nine, and eleven days following the contamination of the insect with the blood of well-marked cases of yellow fever, early in the disease, without any effect whatever being produced by the bite. Thus in one case no result followed the bite of fourteen mosquitoes which four days previously had been contaminated by biting a case of yellow fever on the first day. Again, seven days later, or eleven days after contamination, the surviving seven of these insects failed to infect an individual. On the seventeenth day after contamination, however, the bite of four of these mosquitoes—all that remained of the original fourteen—was promptly followed by an attack of yellow fever in the same individual. These insects had been kept, during the whole of this time, at an average temperature of 82 F.

Our observations would seem to indicate that after the parasite has been taken into the mosquito's stomach, a certain number of days must elapse before the insect is capable of re-conveying it to man. This period doubtless represents the time required for the parasite to pass from the insect's stomach to its salivary glands, and would appear to be about twelve days in summer weather, and most probably about eighteen or more days during the cooler winter months. It follows, also, that our observations do not confirm Finlay's opinion that the bite of the contaminated mosquito may confer immunity against a subsequent attack of yellow fever. In our experience, an individual may be bitten on three or more occasions by contaminated mosquitoes without manifesting any symptoms of disturbance to health, and yet promptly sicken with yellow fever within a few days after being bitten by an insect capable of conveying the infection.

ACQUIREMENT OF THE DISEASE.

Having shown that yellow fever can be conveyed by the bite of an infected mosquito, it remains to inquire whether this disease can be acquired in any other manner. It has seemed to us that yellow fever, like the several types of malarial fever, might be induced by the injection of blood taken from the general circulation of a patient suffering with this disease. Accordingly we have subjected four individuals to this method of infection, with one negative and three positive results. Reserving the detailed description of these cases to a subsequent occasion, we may state that in one of the positive cases, an attack of pronounced yellow fever followed the subcutaneous injection of 2 c.c. of blood taken from a vein at the bend of the elbow, on the first day of the disease, the period of incubation being three days and twenty-two hours; in the second case, 1.5 c.c. of blood, taken on the first day of the disease, and injected in the same manner, brought about an attack within two days and twelve hours; while in our third case, the injection of 0.5 c.c. of blood taken on the second day of the disease, produced an attack at the end of forty-one hours.

In the case mentioned as negative to the blood injection, the subsequent inoculation of this individual with mosquitoes already proved to be capable of conveying the disease, also resulted negatively. We think, therefore, that this particular individual, a Spanish immigrant, may be considered as one who probably possesses a natural immunity to yellow fever.

It is important to note that in the three cases in which the injection of the blood brought about an attack of yellow fever, careful cultures from the same blood, taken immediately after injection, failed to show the presence of Sanarelli's bacillus.[2]

Our observations, therefore, show that the parasite of yellow fever is present in the general and capillary circulation, at least during the early stages of this disease, and that the latter may be conveyed, like the malarial parasite, either by means of the bite of the mosquito, or by the injection of blood taken from the general circulation.

CAN YELLOW FEVER BE PROPAGATED IN ANY OTHER WAY?

We believe that the general consensus of opinion of both the medical profession and the laity is strongly in favor of the conveyance of yellow fever by fomites. The origin of epidemics, devastating in their course, has been frequently attributed to the unpacking of trunks and boxes that contained supposedly infected clothing; and hence the efforts of health authorities, both state and national, are being constantly directed to the thorough disinfection of all clothing and bedding shipped from ports where yellow fever prevails. To such extremes have efforts at disinfection been carried, in order to prevent the importation of this disease into the United States, that, during the epidemic season, all articles of personal apparel and bedding have been subjected to disinfection, sometimes both at the port of departure and at the port of arrival; and this has been done whether the articles have previously been contaminated by contact with yellow fever patients or not. The mere fact that the individual has resided, even for a day, in a city where yellow fever is present, has been sufficient cause to subject his baggage to rigid disinfection by the sanitary authorities.

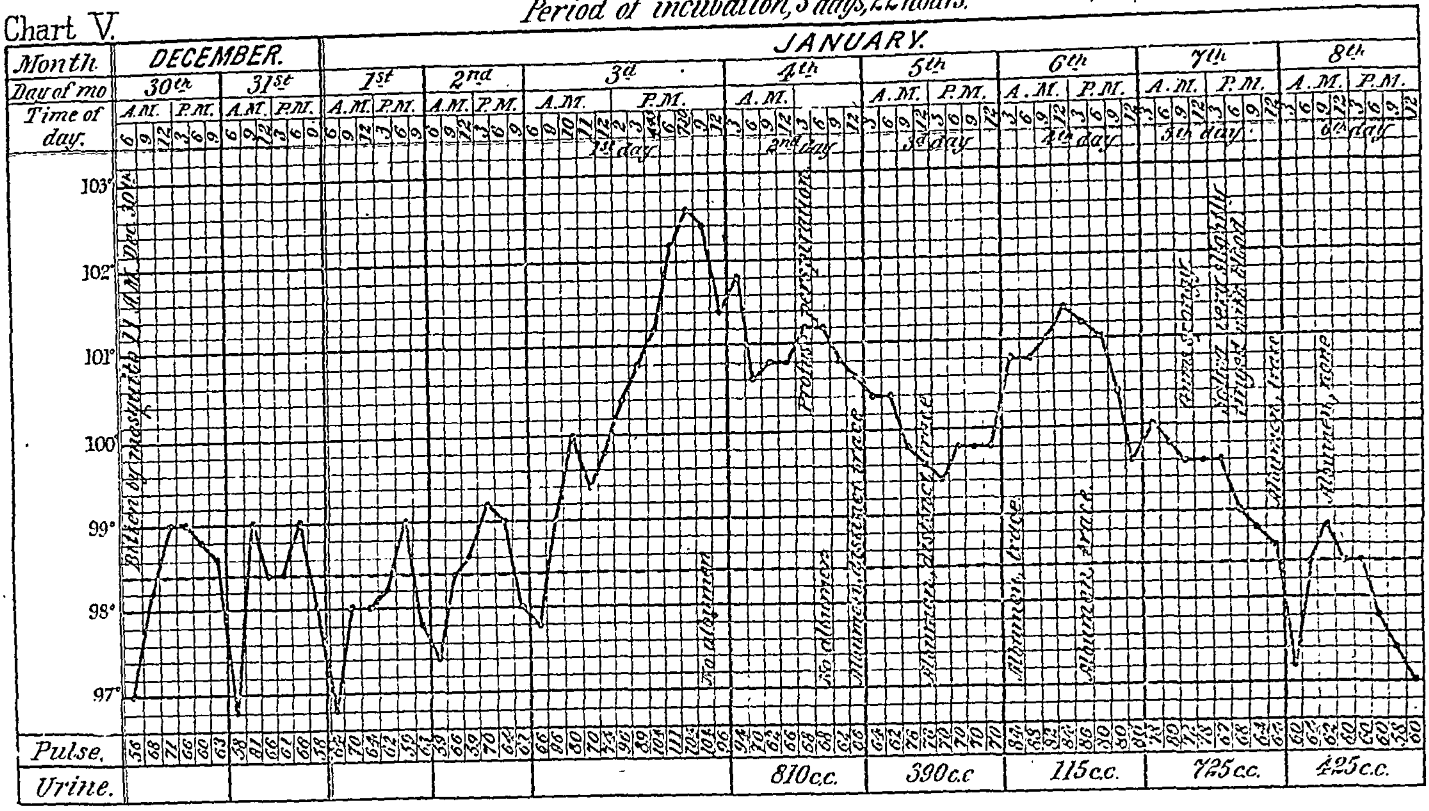
---

[2] A fourth case of yellow fever, severe in type, has been produced by the subcutaneous injection of 1 c.c. of blood taken from the general circulation on the second day of the disease, the period of incubation being three days and one hour. The patient from whom the blood was obtained was an experimental case which was in turn produced by the injection of blood—0.5 c.c.—derived from a non-experimental case of fatal yellow fever. As "controls," Cases 1, 4, 6 and 7 of this report were also injected subcutaneously with 1 c.c. of the same blood without manifesting any symptoms whatever. The blood which produced this fourth case of yellow fever, when transferred at the same time to bouillon tubes in considerable quantities, gave no growth whatever.

To determine, therefore, whether clothing and bedding, which have been contaminated by contact with yellow fever patients and their discharges, can convey this disease is a matter of the utmost importance.

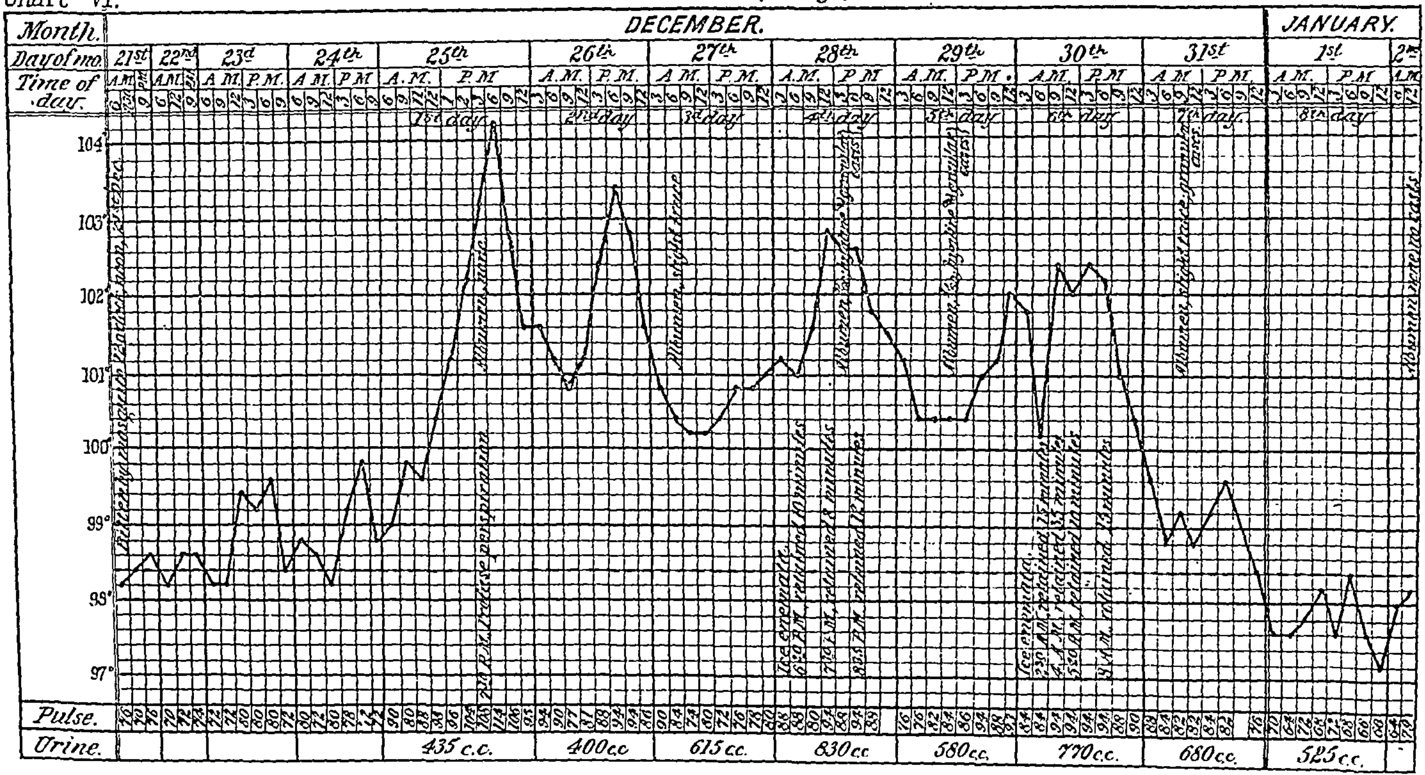
Yellow fever, produced by the bite of Culex fasciatus.
Period of incubation, 3 days, 22 hours.

Chart V.



Yellow fever, produced by the bite of Culex fasciatus.
Period of incubation, 3 days, 23 hours.

Chart VI.



Although the literature contains many references to the failure of such contaminated articles to cause the disease, we have considered it advisable to test, by actual experiment on non-immune human beings, the theory of the conveyance of yellow fever by fomites, since we know of no other way in which this question can ever be finally determined.

For this purpose there was erected at Camp Lazear a small frame house consisting of one room 14x20 feet, and known as "Building No. 1," or the "Infected Clothing and Bedding Building." The cubic capacity of this house was 2800 feet. It was tightly ceiled within with "tongue and grooved" boards, and was well battened on the outside. It faced to the south and was provided with two small windows, each 26x34 inches in size. These windows were both placed on the south side of the building, the purpose being to prevent, as much as possible, any thorough circulation of the air within the house. They were closed by permanent wire screens of .5 mm. mesh. In addition sliding glass sash were provided within and heavy wooden shutters without; the latter intended to prevent the entrance of sunlight into the building, as it was not deemed desirable that the disinfecting qualities of sunlight, direct or diffused, should at any time be exerted on the articles of clothing contained within this room. Entrance was effected through a small vestibule, 3x5 feet, also placed on the southern side of the house. This vestibule was protected without by a solid door and was divided in its middle by a wire screen door, swung on spring hinges. The inner entrance was also closed by a second wire screen door. In this way the passage of mosquitoes into this room was effectually excluded. During the day, and until after sunset, the house was kept securely closed, while by means of a suitable heating apparatus the temperature was raised to 92 to 95 F. Precaution was taken at the same time to maintain a sufficient humidity of the atmosphere. The average temperature of this house was thus kept at 76.2 F. for a period of sixty-three days.

Nov. 30, 1900, the building now being ready for occupancy, three large boxes filled with sheets, pillow-slips, blankets, etc., contaminated by contact with cases of yellow fever and their discharges were received and placed therein. The majority of the articles had been taken from the beds of patients sick with yellow fever at Las Animas Hospital, Havana, or at Columbia Barracks. Many of them had been purposely soiled with a liberal quantity of black vomit, urine, and fecal matter. A dirty "comfortable" and much-soiled pair of blankets, removed from the bed of a patient sick with yellow fever in the town of Quemados, were contained in one of these boxes. The same day, at 6 p.m., Dr. R. P. Cooke, Acting Assistant-Surgeon, U. S. A., and two privates of the hospital corps, all non-immune young Americans, entered this building and deliberately unpacked these boxes, which had been tightly closed and locked for a period of two weeks. They were careful at the same time to give each article a thorough handling and shaking in order to disseminate through the air of the room the specific agent of yellow fever, if contained in these fomites. These soiled sheets, pillow-cases and blankets were used in preparing the beds in which the members of the hospital corps slept. Various soiled articles were hung around the room and placed about the bed occupied by Dr. Cooke.

From this date until Dec. 19, 1900, a series of twenty days, this room was occupied each night by these three non-immunes. Each morning the various soiled articles were carefully packed in the aforesaid boxes, and at night again unpacked and distributed about the room. During the day the residents of this house were permitted to occupy a tent pitched in the immediate vicinity, but were kept in strict quarantine.

December 12, a fourth box of clothing and bedding was received from Las Animas Hospital. These articles had been used on the beds of yellow fever patients, but in addition had been purposely soiled with the bloody stools of a fatal case of this disease. As this box had been packed for a number of days, when opened and unpacked by Dr. Cooke and his assistants, on December 12, the odor was so offensive as to compel them to retreat from the house. They pluckily returned, however, within a short time and spent the night as usual.

December 19 these three non-immunes were placed in quarantine for five days and then given the liberty of the camp. All had remained in perfect health, notwithstanding their stay of twenty nights amid such unwholesome surroundings.

During the week, December 20-27, the following articles were also placed in this house, viz.: pajamas suits, 1; undershirts, 2; night-shirts, 4; pillow-slips, 4; sheets, 6; blankets, 5; pillows, 2; mattresses, 1. These articles had been removed from the persons and beds of four patients sick with yellow fever and were very much soiled, as any change of clothing or bed-linen during their attacks had been purposely avoided, the object being to obtain articles as thoroughly contaminated as possible.

From Dec. 21, 1900, till Jan. 10, 1901, this building was again occupied by two non-immune young Americans, under the same conditions as the preceding occupants, except that these men slept every night in the very garments worn by yellow fever patients throughout their entire attacks, besides making use exclusively of their much-soiled pillow-slips, sheets and blankets. At the end of twenty-one nights of such intimate contact with these fomites, they also went into quarantine, from which they were released five days later in perfect health.

From January 11 till January 31, a period of twenty days, "Building No. 1" continued to be occupied by two other non-immune Americans, who, like those who preceded them, have slept every night in the beds formerly occupied by yellow fever patients and in the night-shirts used by these patients throughout the attack, without change. In addition, during the last fourteen nights of their occupancy of this house they have slept, each night, with their pillows covered with towels that had been thoroughly soiled with the blood drawn from both the general and capillary circulation, on the first day of the disease, in the case of a well-marked attack of yellow fever. Notwithstanding this trying ordeal, these men have continued to remain in perfect health.

The attempt which we have therefore made to infect "Building No. 1," and its seven non-immune occupants, during a period of sixty-three days, has proved an absolute failure. We think we can not do better here than to quote from the classic work of La Roche.[3] This author says: "In relation to the yellow fever, we find so many instances establishing the fact of the non-transmissibility of the disease through the agency of articles of the kind mentioned, and of merchandise generally, that we can not but discredit the accounts of a contrary character assigned in medical writings, and still more to those presented on the strength of popular report solely. For if, in a large number of well authenticated cases, such articles have been handled and used with perfect impunity—and that, too, often under circumstances best calculated to insure the effect in question—we have every reason to conclude, that a contrary result will not be obtained in other instances of a similar kind; and that consequently the effect said to have been produced by exposure to those articles, must—unless established beyond the possibility of doubt—be referred to some other agency.

---

[3] R. La Roche: Yellow Fever, vol. ii, p. 516, Philadelphia.

The question here naturally arises: How does a house become infected with yellow fever? This we have attempted to solve by the erection at Camp Lazear of a second house, known as "Building No. 2," or the "Infected Mosquito Building." This was in all respects similar to "Building No. 1," except that the door and windows were placed on opposite sides of the building so as to give through-and-through ventilation. It was divided, also, by a wire-screen partition, extending from floor to ceiling, into two rooms, 12x14 feet and 8x14 feet respectively. Whereas, all articles admitted to "Building No. 1" had been soiled by contact with yellow fever patients, all articles admitted to "Building No. 2" were first carefully disinfected by steam before being placed therein.

On Dec. 21, 1900, at 11.45 a.m., there were set free in the larger room of this building fifteen mosquitoes—C. fasciatus—which had previously been contaminated by biting yellow fever patients, as follows: 1, a severe case, on the second day, Nov. 27, 1900, twenty-four days; 3, a well-marked case, on the first day, Dec. 9, 1900, twelve days; 4, a mild case, on the first day, Dec. 13, 1900, eight days; 7, a well-marked case, on the first day, Dec. 16, 1900, five days—total, 15.

Only one of these insects was considered capable of conveying the infection, viz., the mosquito that had bitten a severe case twenty-four days before; while three others—the twelve-day insects—had possibly reached the dangerous stage, as they had been kept at an average temperature of 82 F.

At 12, noon, of the same day, John J. Moran—already referred to as Case 2 in this report—a non-immune American, entered the room where the mosquitoes had been freed, and remained thirty minutes. During this time he was bitten about the face and hands by several insects. At 4.30 p.m., the same day, he again entered and remained twenty minutes, and was again bitten. The following day, at 4.30 p.m., he, for the third time, entered the room, and was again bitten.

Case 7.—On Dec. 25, 1900, at 6 a.m., the fourth day, Moran complained of slight dizziness and frontal headache. At 11 a.m. he went to bed, complaining of increased headache and malaise, with a temperature of 99.6 F., pulse 88; at noon the temperature was 100.4 F., the pulse 98; at 1 p.m., 101.2 F., the pulse 96, and his eyes were much injected and face suffused. He was removed to the yellow fever wards. He was seen on several occasions by the board of experts and the diagnosis of yellow fever confirmed. (See Chart 6.)

The period of incubation in this case, dating from the first visit to "Building No. 2," was three days and twenty-three hours. If reckoned from his last visit it was two days and eighteen hours. There was no other possible source for his infection, as he had been strictly quarantined at Camp Lazear for a period of thirty-two days prior to his exposure in the mosquito building.

During each of Moran's visits, two non-immunes remained in this same building, only protected from the mosquitoes by the wire-screen partition. From Dec. 21, 1900, till Jan. 8, 1901, inclusive—eighteen nights—these non-immunes have slept in this house, only protected by the wire screen partition. These men have remained in perfect health to the present time.

December 28, after an interval of seven days, this house was again entered by a non-immune American, who remained twenty-five minutes. The subject was bitten by only one insect. The following day he again entered and remained fifteen minutes, and was again bitten by one mosquito. The result of these two visits was entirely negative. As the mortality among the insects in this room, from some unknown cause, had been surprisingly large, it is possible that the subject was bitten by insects not more than thirteen days old, in which case they would probably not infect, since they had been kept for only five days at a temperature of 82 F., and for eight days at the mean temperature of the room, 78 F.

Be this as it may, nothing can be more striking or instructive as bearing upon the cause of house infection in yellow fever, than when we contrast the results obtained in our attempts to infect Buildings No. 1 and No. 2; for whereas, in the former *all* of seven non-immunes escaped the infection, although exposed to the most intimate contact with the fomites for an average period of twenty-one nights each; in the latter, an exposure, reckoned by as many minutes, was quite sufficient to give an attack of yellow fever to one out of two persons who entered the building—50 per cent.

Thus at Camp Lazear, of 7 non-immunes whom we attempted to infect by means of the bites of contaminated mosquitoes, we have succeeded in conveying the disease to 6, or 85.71 per cent. On the other hand, 7 non-immunes whom we tried to infect by means of fomites, under particularly favorable circumstances, we did not succeed in a single instance. Out of a total of 18 non-immunes whom we have inoculated with contaminated mosquitoes, since we began this line of investigation, 8, or 44.4 per cent., have contracted yellow fever. If we exclude those individuals bitten by mosquitoes that had been kept less than twelve days after contamination, and which were, therefore, probably incapable of conveying the disease, we have to record eight positive and two negative results—80 per cent.

CONCLUSIONS.

1. The mosquito—C. fasciatus—serves as the intermediate host for the parasite of yellow fever.

2. Yellow fever is transmitted to the non-immune individual by means of the bite of the mosquito that has previously fed on the blood of those sick with this disease.

3. An interval of about twelve days or more after contamination appears to be necessary before the mosquito is capable of conveying the infection.

4. The bite of the mosquito at an earlier period after contamination does not appear to confer any immunity against a subsequent attack.

5. Yellow fever can also be experimentally produced by the subcutaneous injection of blood taken from the general circulation during the first and second days of this disease.

6. An attack of yellow fever, produced by the bite of the mosquito, confers immunity against the subsequent injection of the blood of an individual suffering from the non-experimental form of this disease.

7. The period of incubation in thirteen cases of experimental yellow fever has varied from forty-one hours to five days and seventeen hours.

8. Yellow fever is not conveyed by fomites, and hence disinfection of articles of clothing, bedding, or merchandise, supposedly contaminated by contact with those sick with this disease, is unnecessary.

9. A house may be said to be infected with yellow fever only when there are present within its walls contaminated mosquitoes capable of conveying the parasite of this disease.

10. The spread of yellow fever can be most effectually controlled by measures directed to the destruction of mosquitoes and the protection of the sick against the bites of these insects.

11. While the mode of propagation of yellow fever has now been definitely determined, the specific cause of this disease remains to be discovered.

[For discussion see p. 461.]

THE METRIC SYSTEM.*

FRANK G. WHEATLEY, M.D.
NORTH ABINGTON, MASS.

"Frenchmen have beheaded their king, declared there is no God, and are now trying to enforce the metric system!" said a member of the English parliament in the course of an alleged argument against the system. This is a fair sample of the arguments advanced against it. It is not my purpose to make any extended argument in favor of it, taking it for granted that The Association is already, theoretically at least, converted to it. If there are any who are still in doubt upon the subject, I ask them to consider the following résumé:

The system is recommended: 1, because it is simple; 2, it saves time; a good authority on the subject estimates that its employment would save one year of school life for each child; 3, it is cosmopolitan; 4, it is scientific; 5, it is in use in the United States Coast Survey Service, in the Marine-Hospital Service and in the U. S. Navy.

Against its use are the following considerations: 1, it discards an old and familiar system; 2, it is impossible to forget the old system; 3, the accuracy of the standard meter has been questioned by some mathematicians.

Leaving the question here, I propose to consider its present status in the medical profession, and suggest some measures that would hasten its general adoption. Although legalized in 1866, and advocated by a very large majority of the scientific men of the country, a very small number of medical men make use of it to-day. After a somewhat extended investigation in regard to its use in Boston and vicinity, I am of the opinion that Whelply, of St. Louis, was entirely safe when he made the statement in Washington recently that 5 per cent. or less of those writing prescriptions to-day employ the decimal notation.

An inquiry regarding the standing of the men using the metric system was universally answered by the statement that they are the leading men in the profession. So I am inclined to think that while numerically the percentage is perhaps disappointingly small, if we consider quality rather than quantity the showing is quite satisfactory. And when we consider the radical nature of the change, and that natural inertia of which we are all more or less victims, perhaps we shall agree that the progress is as great as we could reasonably expect.

What can we do as individuals to increase this percentage? First, learn to think in the new system, and teach others to do the same. Just so long as we spend our time comparing the new system with the old, and devising rules for their easy interconversion, just so long shall we make slow progress. The equivalent of a grain in terms of the new system is, in my judgment, enough to remember, and when the new system is fully established, forget even that.

There are, besides this individual action, three important factors that would help to a solution of the problem. Let the Association of Medical Colleges and the Pharmaceutical Association, and the Association of Dental Schools, insist that hereafter no one shall receive a degree either in medicine, dentistry or pharmacy, until he has a working knowledge of the system. Let all three associations urge on the writers of text-books the exclusive use of the system. Let the manufacturers of pharmaceutical products label their packages exclusively in the new system. If these conditions could be fulfilled, a tremendous stride would be made toward the universal use of the metric system. Of these three propositions, I am inclined to think the latter is the most important. So universal has become the use of tablets, that if they were all labeled as suggested, almost every practicing physician would be taking daily lessons. In talking with drug houses on this subject, they say if it could be brought about by general agreement, it would be a good thing, but if one or two firms only should adopt the plan, loss of trade is feared. E. R. Squibb & Sons have for many years adopted this method, and the firm deserves much credit, not only for this, but for their persistent and intelligent presentation of the subject in their publications.

DISCUSSION.

Dr. E. H. Bartley, of New York City, by invitation, opened the discussion. He has been using the metric system in writing his prescriptions for twenty years, and adopted a prescription blank with a vertical line near the right hand margin, to take the place of the decimal point. To the left of this line he had printed "gram," and, to the right, "milligram," and is in the habit of filling out all the three places, if necessary, using ciphers. He uses only these two denominations. He thinks the use of the terms centigram and decigram is confusing and unnecessary and they ought to be dropped. Having been a chemist before he studied medicine, he has learned to use the metric system, prefers it for prescription writing, and has always used it. He has learned the doses of remedies in the English system, and has continued to do so because it is difficult to carry in the mind the doses in two different systems and it increases the danger of errors. He thinks it much safer, for the present at least, to carry in the mind the dosage in grains and minims and make the conversion at the time of writing the prescription. This is very easy if we adopt the plan of always writing for two, three, or four ounces. When he first began writing prescriptions, he learned a rule which has worked very well, *viz.: In 60 c.c., or ℥ii, the number of* grams to be written for will equal the number of grains or minims of the active ingredient in each teaspoonful of the mixture. Thus, if you wish to give ten grains of iodid of potassium at a dose, you would write

Potassii iodidi	10|000
Aquæ q. s. ad	60|000

M. ft. sol. To be given in dram doses.

Each dram contains ten grains of the salt. This prescription contains fifteen doses. In a three-ounce mixture, or 90 c.c., the number of grams to be taken would be 1½ times the dose, and in a four-ounce mixture, 120 c.c., it would be double the dose, in grains, in each dram, or just equal to it if the dose be increased to two drams, or a dessertspoonful.

As regards the liability of mistakes on the part of the pharmacist in dispensing a prescription written in metric form, he has only twice in twenty years, had a pharmacist make a mistake in the quantity prescribed. In one case the pharmacist put in double the quantity of water ordered, and the patient got less than the prescribed dose, and the other was similar to it. But the danger of this is getting less every year. The pharmaceutical schools now make the use of the metric system compulsory with their students, so that all druggists will soon be familiar with it, and the danger, from their side, will become extremely small. The dangers even now are very little from that source. The only one is that arising from physicians attempting to translate from one system to the other; but by adopting the method just described, there can be very little danger from that side.

---

*Presented to the Section on Materia Medica, Pharmacy and Therapeutics, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Prof. Jos. P. Remington, Philadelphia—With regard to the remark just made about teaching the metric system in pharmaceutical schools, in the College of Pharmacy of Philadelphia, the metric system is used almost exclusively. In the laboratory work no other is used. One point raised in the paper was the question of competency of the pharmacist and his liability to error; every educated pharmacist throughout the country would fill the prescriptions in the metric system just as well as by the old method. In 1890, the United States Pharmacopeia introduced in its liquid formulæ the metric system, so that the use of this system is extending. The great difficulty is in getting physicians to abandon the old and take up the new. In Germany, the matter was regulated by law and physicians were given one year in which to learn the metric system, and were obliged to use it thereafter; but we can not adopt such summary methods in this country.

Dr. Frank Woodbury, Philadelphia, said that he thought that the decimal point and the ciphers repelled many physicians, and the adoption of the plan of writing quantities in grams, centigrams and milligrams in whole numbers, without the use of the decimal point, might greatly assist the transition from the old to the new and reduce the liability to error.

Dr. J. N. Upshur, Richmond, Va., wished to say very emphatically that what Dr. Wheatley said about the indolence of old doctors is true; in this connection, he was much impressed with the truth of the saying that you can not teach an old dog new tricks. Speaking for himself, he did not believe that he could learn that metric system, and carry it into effect in writing his prescriptions, without killing somebody. At the same time he urges his students to learn the metric system. His son, who uses it in the U. S. Marine-Hospital Service, complains of the unprogressiveness of the druggists in his locality, which compel him to write his prescriptions for his private patients in the old system.

Dr. F. G. Wheatley, in closing, said that the point raised that the writing of ciphers constituted an objection was not very practical. His own method is to only keep two denominations in mind, the grams and the centigrams, just as we have dollars and cents. Notwithstanding what had just been said, he thinks that it is the physicians who are at fault in this matter. The druggists who have graduated during recent years say that when they graduated they knew nothing about any other system than the metric, but they had to learn the old method on account of the prescriptions received. The fault lies with the teachers in the medical colleges. As long as the text-books teach both systems, the average physician will learn the old and leave the new.

EVOLUTIONAL AND INVOLUTIONAL TYPES OF MENTAL AND NERVOUS DISEASE.*

EDWARD E. MAYER, A.M., M.D.
Lecturer on Nervous Diseases at Western Pennsylvania Medical College.
PITTSBURG, PA.

The different epochs of life are factors of great moment both in the production and in the exacerbation of nervous instability. They are rarely passed through, even in the most healthy individual, without some psychical or physical manifestation. Each crisis in life determines new impulses, new thought, and new actions, which give each epoch a distinct physiology and psychology. We purpose to discuss in this paper the effect these periods have upon the brain and nervous constitution, considering chiefly the minor and transient disorders influenced or excited by them, and to attempt to explain the preventive measures necessary and advisable, possible and ideal, which may determine their development. The territory that we especially wish to cover shades insensibly into the two extremes, mental soundness and mental disease. This borderland is especially important on acount of the fact that the psychoses as a rule gradually pass through a prodromic stage of nervous instability or one of recedent psychical action instead of being ushered in or terminated abruptly. Such conditions are psychopathic, but can not be grouped under the psychoses *sensu strictiori*. There is no disease which does not alter the mental state of the patient, nor is there any one whose physical state is not influenced by his mental condition. We desire to emphasize this point, as it illustrates a common law of cause and effect present in many disorders. The brain then controls the body just as much as physical states influence the mental. Each successive epoch adds a new burden upon the nervous system, and in unstable individuals it is only a question of time until the inherited instability reveals itself. The types of each period differ according to the intensity and rapidity of incidence and the physical manifestations. Nevertheless the disturbances do not include any disorder which can not be caused by other factors also. As an etiologic classification, however, we are justified in grouping them in this manner.

In childhood inherited strain is rarely noticed. At this period there is great difficulty in determining what is physiologic and what is psychologic. For instance, every experienced mother knows that a child does not always reveal a tired condition by a desire to sleep and a feeling of listlessness, but often by excitability and restlessness. When irritability and peevishness is observed as a result of physical exhaustion, we must regard it as evidence of the influence of physical states upon mental conditions, though it is natural and not pathologic. When threats of whipping, etc., are added to this, we find an artificially produced nervous instability with conditions of anxiety predominating, expressed by night terrors, loss of appetite, restlessness, etc

Mental exhaustion may, however, without any such stimulus as whipping, terminate in diseased over-exhaustion. Here also irritability is the chief sign, but it is more marked than in the common evening exhaustion or is accompanied by other phenomena, particularly if a nervous taint is inherited. The child becomes quarrelsome, envious and imperious, or is timid and anxious, awkward and easily moved to tears. It tires easily, but does not sleep readily, tosses around, emits a shrill cry in its sleep, or talks to itself and does not awake refreshed as do normal children. These symptoms are too often looked upon as being due to gastric disturbances, without any efforts being made to combat them, and are allowed to take their course. It is unmistakably a diseased type of exhaustion, expressed in a transient disturbance of physical and mental functions.

Another condition at this period, due to inherited strain, is morbid depression. Children of this type are always reserved and gloomy, precocious and hypersensitive. In some this condition only exists in the early morning for a short time after awakening. This transient depression or melancholy is the precursor of melancholia in the adult.

We have in childhood different dislikes identical with those in adults, but which are often mistakenly supposed to be natural in children.

A child who may have been bathed many times before without evincing any signs of fear, may suddenly become restless when immersed, crying and drawing up its legs, as if in pain. It may be due to many causes and always demands investigation. More easily recognized and more common is the fear of being alone. In some, of course, this is due to the mother or nurse spoiling the child, but in others it comes on suddenly without any such cause and may be indicative of some general nervous disorder. Fear of strangers is also not always physiologic. Every physician can probably recall some child formerly friendly to him who suddenly became fretful and cried at his approach, who steadily refused to allow him to touch it, and in time acted similarly to all except its mother, the latter being compelled to stay with it constantly until as suddenly as it came, the fear vanished.

---

* Presented to the Section on Nervous and Mental Diseases, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

The best known form of infantile fear is pavor nocturnus. As this is generally so pronounced as to be a true psychosis, it will only be lightly touched upon. The onset of the nervous storm in such children can generally be predicted. Such a child is paler than usual, more irritable, can not go to sleep unless its mother is with it, and awakes as soon as she attempts to leave. Close observation will reveal some muscular twitchings, which increase in intensity, until suddenly the outburst comes on, during which the child may even be in a condition of transient mania. Nightmare must, however, not be confused with these night terrors.

Transient exaltation of spirits is common in children. Anticipation of the slightest pleasure will make its eyes sparkle, make it become restless and babble incessantly, cause it to laugh unceasingly and act somewhat as does an adult under the influence of alcohol. Parents generally stand complacently observing it and do not seek to repress this unnatural excitation until suddenly the picture changes. The child becomes listless, cries, and upon being taken to bed tosses about, and after it has gone to sleep, awakes frequently with a cry of anxiety.

A child who has inherited a neurotic constitution is generally below the normal weight and is apt to be precocious. Even the laity is apt to be suspicious of a too bright mind in a frail body. It may be due to malnutrition, rachitis, etc., or to the fact that the parents are small in stature and that the psychic life has simply been developed too early. But most often a neurotic taint is back of it.

Single nervous symptoms observed at this period are senseless laughter, a staring look, twitchings of the facial muscles, spasms, both local and general, stammering and stuttering, and strabismus. These symptoms may occur particularly during teething. A healthy child generally teethes without trouble. But when the nervous resistance is congenitally weak, the physical strain makes excessive demands upon the nervous system whose instability then manifests itself. Such children reveal their "nervousness" in other ways. Their facial color may rapidly change from bloom to pallor, they vomit easily, cry in their sleep, are domineering, early learn to comprehend spoken language and have pronounced retentive powers. Such symptoms reveal a nervous temperament. When in addition we find stubbornness, viciousness and perverse habits, as instinctive masturbation, it reveals an inherited taint in addition to a nervous temperament. When we also find the so-called stigmata of degeneration, we are dealing with a case of congenital degeneration. No single symptom, however, proves anything; it is only by a combination of symptoms that we can determine such conditions. As the child grows older, other neurotic manifestations may come on. These include a marked and unexplainable anemia, nervous snuffling, peculiar stubborn headaches and slight variations of character, mentation and habits occurring periodically.

The older the child is the more diverse are the conditions found, environmental influences being added to the autochthonous. This is the period of life when hypochondriac ideas, excessive desire for order and cleanliness and even religious exaltation first become evident.

The earlier the signs of nervous disturbance occur, the more frequent and pronounced they are, the more probable is the belief that they are due to congenital degeneration. It is natural, therefore, to find the hereditary ataxias and muscular atrophies, Thompson's disease (toxemic?) at this period of life.

The next period of life, the school or prepubescent age, is very similar, except that the physiologic and pathologic states are more difficult to separate. Emotion is no longer supreme, the muscular system now asserts itself, and the faculty of judgment and cognition comes into play. Children at this age are able to facilitate as well as to hinder the development of their faculties, and parents may consciously or unconsciously inculcate bad habits in their children by example or by improper methods of training and discipline. Chorea, "insanity of the muscles," is the type of motor disturbance and is found at this age; also petit mal, unconscious automatism or somnambulism, and migraine. The brain is now rapidly developing and the cortex is asserting itself. Muscular impulses dominate the scene and hence the nervous disorders are largely muscular.

The signs of degeneration noticed are flat-pointed teeth, hacking cough, a capricious appetite, and a scanty urine. The objective signs are slowness in movement, stooping, and twitching. We can at this age already observe a tendency to neurasthenia or hysteria, one child having hysteric tendencies, another neurasthenic.

In this period the influence of school-life is the most important factor. Incomplete development, undue sensitiveness, excessive restlessness, the frequent and perplexing changes from one room and teacher to another with entirely different methods, the exactions demanded by educators in their senseless rivalry, the anxiety attendant upon competition for prizes, etc., have a harmful result upon the pupils. There are, of course, some advantages in our system. A timid child becomes accustomed to association with strangers, peculiarities are influenced and often repressed through the ridicule of classmates, improper home training is counteracted, the energy of a child is turned into a particular channel, an irregular life is made methodical, carefulness tends to replace carelessness, etc. But under our present system, where the mental capacity of all children is regarded as equal, and the mental energy is drained to the last drop, in accordance with the forcing process now in vogue, which uses up all reserve power and inhibits the growth of other parts of the brain and prevents the preparation of the body for the momentous crises of life which are yet to come, all the advantages are multiplied. "There is no time nor place of organic repentance provided by nature for some of the sins of the schoolmaster."

The next period of life embraces puberty and adolescence. We include these two epochs in one because they are so intimately associated, one being the termination of the other. Before this time boys and girls are much alike, they are not very different sexually, mentally, or physically; then they gradually develop sexually, and finally mentally; the boy comes to use his judgment and reasoning powers more and more, and the girl becomes more impulsive and emotional. This is not an abrupt change, but is only accomplished after the lapse of some years. The emotions of a girl up to her 21st year are not stable or deep-seated and are soon forgotten; her conversation only then becomes coherent, her actions womanly. A boy becomes manly at about his 24th year, commences then to become precise and settled and deliberate.

Inasmuch as this is the period when the mind develops, it follows that inherited mental characteristics would now show themselves, perhaps for the first time, or more strongly than before. This is, then, the time when we expect hysteria and hemicrania, epilepsy, innate immorality and arrested development, to show themselves. Clouston includes acne, ugliness, many forms of impaired vision, and perhaps phthisis and acute rheumatism as neuroses of this period, but why I do not see. Eccentricity and incompatibility of temper, sexual aversion and religious asceticism, decrease of volitional power, reveal themselves during this period. Many of the first convictions for crime are in those of the adolescent age.

Many diverse factors now come into play. The combat with the outer world begins in earnest; the ability for self-culture and self-responsibility increases; production replaces acquisition. The transition from childhood to this period in woman occurs with the interaction of certain periodical changes which strongly influence the mind. These may come on early or late. It is an unfavorable sign if they come on long after the development of the mind. The effects of an improper education, sexual desires, the emotional development with its alternate display of fear, hope, and disappointment, the indulgence in religious contemplation, the fostering of egotism and self-introspection, the exhaustion attendant upon the exacting duties of social life with its balls, theaters and parties, the daily tyrannizing of an overstrict and zealous father, with perhaps compulsory attendance at church and forced restraint in all daily actions, are the forces at work at this period. The onset of a hysteric attack can often be traced to the preparation for confirmation. In males this is the age when sexual abuse and alcoholism assert their sway and play havoc with the system. The strain of making up new functions is such a burden that it takes little more to upset the system.

The next period, that of adult life, including pregnancy, lactation and parturition in woman is a momentous one. This is a time of trial to a female, even though she is not congenitally predisposed to instability. Reproduction of the species, although it is the duty of women, is likewise a menace to her health. Pregnancy generally evokes mental depression, irresistible longings, irritability, foolish jealousy, anxiety, etc. Hysteric symptoms are also prone to occur at this time. Similar occurrences take place in childbirth and lactation. Chorea and hebephrenia are also common during this time. In the male, family cares, business worries; political, church and social duties; alcoholism and syphilis, and business speculation combine to keep up a ceaseless cerebral congestion. Neurasthenia is for this reason the nervous disease of adult manhood. We may find also eccentricities of character, curious habits, recurrent attacks of depression or of forced gaiety, and in luetic individuals the syphilitic nervous diseases.

Suppression of the menses in females causes many nervous symptoms, particularly stupor, listlessness and headache. Illicit intercourse generally produces pathologic mental changes in woman and if children are begotten the shame and distress often suffice to produce a transient mania.

With the cessation of the power for reproduction, vital energy is lessened. Unstable nervous systems are just as apt to be upset by the process of decadence as they were in their development. The body loses in weight, the circulation slows up, the lymphatic and arterial systems commence to degenerate, the emotions quiet down, the imaginative power disappears, the mental processes alter, etc. These changes do not take place quickly, but cover some years. In woman the disappearance of menses is not coincident with the climacteric. We may find in females at this period, supersensitiveness, sleeplessness, depression of spirits, different phobias and general apathy, and in both sexes, various trophic disturbances. In men the climacteric is not as definite or as complete and occurs later and more gradually than in women. The mental alterations are therefore rarely as pronounced, irritability and a transient depression of spirits are all that is noticed. This is the time of life when cerebral hemorrhage and encephalomalacia are prone to occur.

Physiologic senility is not only slow and insidious in its onset, but has no set time for its occurrence. In general we may say that it commences when atheroma and arcus senilis comes on. Boy-Tessir well says that "the coefficient of the organic faculties varies for each individual. Each by reason of his lessened organic resistance carries from birth a certain predisposition to disease, that is to say, a special grouping of lessened organic resistance upon which depend the time of the appearance of senescence." All functions suffer except that of reproduction, which answers to laws of its own. The springy step, the elastic frame, the lustrous hair, the quick mind become things of the past. The process of thought, though still deliberate and accurate, becomes less rapid, and the association paths seem to become less responsive to the will. The organs become sluggish in action and more susceptible to disease; co-ordinated movements are more difficult; all thoughts, tastes, habits approach again those of youth.

Senility becomes abnormal, according to Clouston, if hereditary cerebral weakness exists, if the brain has been overtaxed, or if its blood-vessels become diseased. Motor impairment is characteristic of this period, revealing itself in paralysis agitans and similar disorders. The melancholia which is often observed is not a "conscious sensitive mental pain, but an automatic motor misery." In others again we find a transient mania due to sudden alterations of the cerebral circulation and to vasomotor paralysis.

Senile abnormalities are however, when not so pronounced as these three types, difficult to distinguish from the physiologic occurrences of senility, because the latter themselves consist in mental and motor changes which at other times of life would be considered abnormal. The senile speech so characteristic of this period, the loss of ideation and of affection, the lessened memory and concentration of thought which are found in physiologic senility, render it difficult to draw appropriate conclusions. But in general, when excessive volubility, desire for unfit marriages, peculiar perversities of temper, wandering tendencies and restlessness—the normal senile always desires rest—indifference, carelessness in habits and hypochondriacal ideas are found, we can regard senescence as having exceeded its physiologic limits.

DISCUSSION.

Dr. Gregg, Hollins, Va.—I wish to express my own peculiar views in regard to what was said in connection with the evolution of nervous disease from its mental aspect. I have never believed in mental evolution. I can conceive of no evolution of mind, but only of organic evolution. I can conceive of nervous evolution. I can understand brain development; improvement of the various centers of the brain. I understand improvement in the intellectual centers of the brain, the psychic centers; but I can not understand any evolution, or impairment or advancement in mind, and I believe we often confound mental and cerebral functions. I can understand how machinery can be perfected for the application of the power of electricity, and a very ordinary machine can be converted into a very fine machine, but this would not be the evolution of electricity.

Dr. Edward E. Mayer—I confess my inability to exactly understand the gentleman; it seems to me that he is indulging in a play of words. I wish that he would exactly define what he means by mental functions and by cerebral functions. He assuredly has not in mind the old metaphysical views on this question. The mental functions must certainly develop with the development of the mind. The mind of a child is perfectly blank, and to a certain extent we can write on it what we wish. The older it becomes, the more developed its brain is; the more receptive is its mind. The doctor's comparison with a machine is rather inappropriate in our estimation. We are not dealing with material actions or products, but with chemic and vital forces. At the present day, metaphysical abstractions are certainly not in place among a body of physicians.

ANASTOMOSIS OF THE URETERS WITH THE INTESTINE.

A HISTORICAL AND EXPERIMENTAL RESEARCH.*

REUBEN PETERSON, M.D.

Professor of Gynecology Post-Graduate Medical School; Assistant Clinical Professor of Gynecology, Rush Medical College; President of the Chicago Gynecological Society.

CHICAGO.

The experimental work forming the basis of this article was undertaken with the view of studying the changes resulting from anastomosing the ureters with the intestinal tract, and of determining whether the procedure could with safety be employed in human beings. The labors of other experimenters in this field have abundantly demonstrated that in dogs, at least, the large bowel can be employed as a receptacle for urine and the animal have good control over its anal sphincter, and liquid feces be evacuated at regular intervals without resulting proctitis. But the more important and far-reaching changes in the kidneys and ureters, resulting from the bacterial invasion from the septic cavity into which the ureteral orifices open, has not been satisfactorily studied.

Will infection of the kidney invariably follow its ureteral union with the intestine? If this be true, can perfection of operative technique reduce this infection to a minimum, so that the kidney can recover and remain a useful organ? To the thoughtful, conscientious surgeon these questions are paramount, and must be carefully answered before he decides to subject his patient to an operation from which, once performed, there is no retreat.

My work, as the title indicates, has been in two directions: First, I have carefully, and I trust exhaustively, gone over the literature of the subject. This was a task of considerable magnitude, as some of the cases were hidden away in transactions or obscure reports. In many instances the original had been quoted incorrectly and the error handed down from one writer to another. In most instances the abstracts have been made from the original sources, or, at least, the original has been gone over carefully to verify the abstract. I have endeavored to arrange the material in such a form as to be of service to future investigators.

The second portion of the article is devoted to my own experiments, from which, together with the work of others, my general conclusions are drawn.

From a historical standpoint Richardson's[83] case merits the first consideration, since it is the only one of its kind on record. The case was reported in the "Philosophical Transactions" in the year 1713, and is as follows:

"One John Woosnape, of North Bierly, a poor boy, lived till he was 17 years of age and never made water, and yet was very healthy, vigorous, and active. He had constantly diarrhea on him, but without much uneasiness. The obstruction must have been in the kidneys, for he never had any inclination to make water. The serous part of the blood, which should have been thrown off by the urine, was discharged by the celiac and mesenteric arteries by the mediation of the glands into the guts. He died of a fever."

It is certainly difficult to decide from this report whether the author actually saw or only heard of the case. At any rate, from a scientific standpoint it is practically useless, and certainly does not warrant the deduction that the human being can live seventeen years with a blending of the urinary and intestinal tracts. Yet, after a mention of the cloaca in certain animals, and deducing from this that the same condition may be produced in man and be compatible with life, certain writers have endeavored to clinch the argument by referring to Richardson's case. That some of them have never read the original is apparent, from the fact that the reference is incorrectly given.

ANIMAL EXPERIMENTS IN URETERO-INTESTINAL ANASTOMOSIS.

Can the results of animal experimentation with uretero-intestinal anastomosis be used to advantage in establishing the place of the operation in human surgery?

In a general way this query can be answered in the affirmative. In spite of the technical difficulties of the operation in an animal, such as the dog, it is possible to so perfect the technique as to greatly reduce the primary mortality, and the same may be said of the operation in man. Gross errors in technique should not be counted in determining the value of the operation either in animals or human beings. While it may be true, as claimed by some, that the human kidney is a more highly developed organ than is that of the dog, it is true only to a limited extent that its power of resisting infection is thereby greater.

Various objections to animal experimentation as a test of the value of uretero-intestinal implantation in man have been raised, but they can not be said to be upheld by facts. Certainly the upright or prone position can have absolutely no influence on the action of the colon bacillus in producing an ascending pyelonephritis. A septic cavity, such as the rectum, is filled with myriads of these bacteria, and no action of gravity or the mere flushing out of this cavity can make it aseptic to any appreciable degree. Nor is it at all probable that the colon bacillus in the dog's rectum is any more virulent than the same germ in the human intestine.

Yet all these theories have been advanced to explain the cause of the failures on the experimenter's part. A careful study of the literature of the subject as well as the results of my own experimental work have con-ed me that identical changes take place in both ani- s and man when the ureters are anastomosed with intestinal tract. Hence, I have by means of brief racts placed the work of other experimenters in this d in such a form as to be readily available to the dent of the subject.

---

* Read before the American Gynecological Society, Washington, D. C., May 1, 1900.

LÜCK AND ZELLER,[7] 1881. *Four dogs; both ureters in um; death from peritonitis from giving way of sutures.* retero-intestinal anastomosis in animals dates from the at-mpts of these experimenters to implant the ureters in the tum after removal of the bladder in dogs. Different thods of disposal of the ureters were studied. They succeeded in saving a number of animals where the ureters, either alone or with the trigonum, were fastened in the abdominal incision, but the attempts to anastomose the ureters with the rectum were complete failures. In these last experiments, after removal of the bladder and careful hemostasis, the rectum was incised for 3 or 4 cm. and both ureters secured in the incision by a row of Lembert's sutures. In all four dogs operated on the sutures gave way, with resulting peritonitis and urinary infiltration. In the case of one dog, which lived four days, it is noted that the evacuations were thin and mixed with the urine.

BARDENHAUER,[1] 1886. *Single ureter implanted extraperitoneally in five dogs, with three recoveries; uretero-intestinal stenosis; dilatation of ureters, hydronephrosis, pyelitis, and pyonephrosis.* Bardenhauer experimented on five dogs by exposing extraperitoneally the ascending and descending colon and corresponding ureters. The ureter was then divided and drawn over a curved needle. The needle was made to penetrate the posterior wall of the colon and brought out again 1.5 cm. below the point of entrance. The bowel was invaginated at the site of the puncture and the ureter held in place by sutures, which united the borders of the invaginated portion. The end of the ureters which presented at the deeper opening was cut off and slipped back into the lumen of the bowel and the second opening closed by suture. The operation is mentioned as difficult, owing to the thinness of the ureteral walls, yet in three cases was successful. Two of the surviving animals were killed after four weeks. The union of the ureter with the rectum was perfect, but at the site of the operation there was cicatricial contraction, together with dilatation of the ureters and hydronephrosis. The third dog was allowed to live a year. Toward the last the animal's stools were copious and bloody. The post-mortem showed pyelitis and pyonephrosis.

NOVARO,[16] 1887. *Three dogs, one recovery; both ureters in rectum; one killed at end of four months; ureteral orifices patent; one kidney normal; other dilated from stenosis.* Novaro reported the pathological findings in a dog in which the ureters had been implanted in the rectum four months previously. Two other dogs failed to survive the operation. The animal passed all his urine by the rectum, was continent, and remained well up to the time of his death. The bladder had shrunk to the size of a hazlenut and the ureteral orifices were patent. The right ureter and kidney were normal; the left ureter and corresponding kidney were dilated, probably from a stenosis of the uretero-rectal opening. The rectal wall showed no changes except muscular hypertrophy. From these findings Novaro recommended the operation, and emphasized the fact that it would be much less formidable in man on account of the larger caliber of the ureters and the possibility of employing more stringent antisepsis.

I have been unable to consult Novaro's original article. Van Hook, in speaking of the paper, says that "a microscopic examination of the kidneys was made. The testimony of the pathologist who made the examination is not absolutely unequivocal as to the inflammatory changes, and no bacteriologic examination of the mucous membrane of the pelves of the kidneys and the mucous membrane of the ureters was recorded."

TUFFIER,[23] 1880. *Two dogs; single ureter in rectum; death in four days from peritonitis; uretero-rectal stenosis.* Tuffier endeavored to implant the ureters into the rectum in two dogs. Under the strictest antiseptic precautions the abdomen was opened and 2 cm. of the inferior third of the ureter was isolated, care being taken to preserve the fatty and peritoneal coverings. An elastic ligature was applied about the ureter to prevent the escape of urine. Two strands of fine catgut were passed 1 cm. above the severed end. The intestine was opened by a small incision and the ureter carried into the bowel cavity 1 cm., where it was left freely hanging. The ureter was then carefully sutured to the intestinal wall and the incision closed with a Lembert suture. The animal lived but three days. The autopsy showed an intestinal fistula at the level of the suture and a general peritonitis. The ureter was partially stenosed at the rectal opening, and was already filled with a purulent fluid. The same experiment in another dog resulted in death on the fifth day, and the ureter was again found filled with pus.

TIZZONI AND POZZI,[22] 1888. *Two dogs, one recovery; both ureters implanted into loop of isolated bowel, and latter sutured to neck of bladder.* These experimenters isolated a piece of the small intestine, 7 cm. long, and united its ends, as well as the ends of the remaining bowel tract. A month later the ureters were implanted into this isolated portion of the intestine and the loop sutured to the neck of the bladder. At first the animal was incontinent, but after a while continence was established. The post-mortem two years after the operation showed the isolated loop of bowel empty and a new bladder formed from the neck of the bladder. An attempt to do the operation in one stage was a failure, the dog dying eight days after the operation.

These experiments have been included here, although, strictly speaking, the ureters were not implanted into the intestinal tract. The survival of the animal for such a long period of time shows what would result could the septic nature of the cavity into which the ureters are implanted be dispensed with.

PAOLI AND BUSACHI,[17] 1888. *Four dogs, one recovery; both ureters implanted; stenosis; pyelonephritis.* In four experiments made on dogs the ureters were sutured into the intestine. In nearly every case a constriction developed at the point of exit of the ureter. Two of the dogs died—one of a pyelonephritis, the other of infiltration of the urine; the third presented a dilatation of the intestine with anemia of the corresponding kidney. The fourth animal made a good recovery.

REED,[19] 1892. *Nine dogs; three recoveries; pyelonephritis; hydronephrosis; one kidney normal.* Reed succeeded in implanting one ureter in the rectum in three dogs, but six animals in which a bilateral implantation was attempted died. In the three dogs that survived the ureter was passed through a small slit in the rectum six inches above the anus and held in place by sutures passed through the sero-muscular edges of the bowel and the peritoneum, which had been dissected away with the ureter. The first dog lived ten weeks, but the specimen was lost. The kidney of the second dog was congested and showed evidences of acute nephritis and hydronephrosis. There was a perfect union of ureter and rectum. The third dog was killed twenty-five days after the operation. The left kidney was normal and there was no renal congestion or hydronephrosis. The uretero-rectal opening was patent.

In the six bilateral uretero-rectal anastomoses the ureters were inserted into the bowel three-quarters of an inch. The remainder of the operation was as described above. All the animals died in a few days of peritonitis or nephritis. Post-mortems showed in most instances hydronephrosis. From these experiments Reed concludes that the implantation of one ureter into the rectum is a possible and practical procedure, but that the simultaneous implantation of both ureters is still a questionable surgical procedure.

RÓSCISZEWSKI,[20] 1892. *Six dogs; one recovery; autopsy after three months; ureter thickened; hydronephrosis.* Rósciszewski implanted a single ureter into the rectum in six dogs, of which five died in three to five days of peritonitis due to giving way of the sutures. One dog survived three months. Death resulted from peritonitis following implantation of the other ureter. The post-mortem showed that the uretero-rectal union in the first operation was complete, and that a probe could be passed into the ureteral orifice quite easily. The rectal mucosa was normal. The ureter itself was thickened, and the pelvis of the kidney, which contained a purulent fluid, was considerably dilated. The kidney substance showed evidences of the interstitial changes. Rósciszewski ascribes the failure of the operation to imperfect technique.

(To be continued.)

Doses in German Pharmacopeia.—In the new edition of the Pharmacopeia Germanica patent-protected names are avoided as much as possible and the scientific term used. Salol, for instance, is recorded as phenyl salicylate, etc. The new names introduced in this class are: dermatol as basic bismuth gallate. trional as methyl sulphonal and salipyrin as phenyldimethyl-pyrazolon salicylate. The *Berliner klin. Woch.* quotes some of the new maximal doses with an exclamation point after each. Among them are bromoform, .5 to 1.5; hydrargyrum salicylicum, .02; the single dose of creosote has been changed from .2 to .5. The daily dose of tincture of strychnin is given as 1 to 2; of folia digitalis .2 to 1, and of the tincture, 1.5 to 5.

HEREDITY AS A FACTOR IN THE ETIOLOGY OF PULMONARY TUBERCULOSIS.

Conflicting opinions have at different times existed as to the importance of heredity in the etiology of pulmonary tuberculosis. It is, however, scarcely maintained any longer that the disease itself is so transmitted, but rather that it is some vice of tissue—and therefore some aberration of function—that is thus conveyed from parent to child. Rarely tuberculosis is congenital, but even then the disease is not inherited, but merely acquired by the fetus *in utero* from the mother through the placenta. There can be no tuberculosis without tubercle bacilli, and these bacilli can not be inherited, although the susceptibility to their invasion can be and is. Some interesting data bearing on this subject are presented in a lecture delivered recently by Thomas Oliver.[1] From the statistics of the Mutual Life Insurance Company, of New York, it appears that a family history of tuberculosis indicates a liability to the disease on the part of an applicant for life insurance, and that the amount of this increased liability may be estimated at 30 per cent. This liability is naturally the greater when there is a history of two or more tuberculous persons in a family, and also when the disease occurs in a parent than when it occurs in a brother or sister.

By some it is believed that, of the parents, the mother is more likely than the father to transmit the liability if she herself or her family be tuberculous. The statistics of the Mutual Life Insurance Company, however, indicate the reverse, showing that the percentage of liability to pulmonary tuberculosis between 20 and 29 years is 43.3, when the father, and 36.5 when the mother has died from that disease; between 30 and 39 years the figures are 16.1 and 17.1 respectively; between 40 and 49 years, 10.4 and 7.5 respectively; and above 50 years, 9.6 and 4.6 respectively. In the experience of the Scottish Widows Fund, however, undoubted pulmonary tuberculosis is more frequently transmitted by the mother than by the father, the ratio being 6.29 on the side of the latter, as against 8.97 per cent. on the part of the former.

Tuberculous patients are below the normal in weight. It is an accepted fact that the highest mortality-percentage from tuberculosis and the highest proportion of underweights are encountered before middle age, and the lowest mortality-percentage and the highest proportion of overweights after middle age. In persons with no history of pulmonary tuberculosis in the family twice as many deaths occur among those below as among those above the average weight, while in families with such a history the percentage is greater—a circumstance that indicates that poor physique and enfeebled nutrition play some part in the etiology of the disease. In the experience of the Scottish Widows Fund, 80 per cent. of sufferers from pulmonary tuberculosis fall short of the average weight for height. Light weight and especially losing weight are precursors of pulmonary tuberculosis. Robust bodily development, on the other hand, while not without a favorable influence, does not prevent pulmonary tuberculosis, for the strongest athlete with a splendid physical frame, if a member of a tuberculous family, may succumb to the inherited disease. Neither does robust physical development, even in the absence of a tuberculous family history, insure against the danger of the disease. All are liable, but unequally so.

A study of all the cases admitted into Brompton Hospital for Consumptives, from 1855 to 1880, shows that when there is a family history of pulmonary tuberculosis, the members of that family who become tuberculous do so at an earlier age than do those of a family free from the disease who acquire it; also that when there is a history of tuberculosis in both parents, there is not only greater liability to the disease, but it develops at a still earlier age than when there is but a single inheritance. Among 3000 cases, 38 per cent. occurred in males and 58 per cent. in females who gave a family history of pulmonary tuberculosis. In 80 cases of well-marked family tuberculosis there was a history of paternal inheritance in 24, of maternal inheritance in 30, of double heredity in 24, and of atavism in 12. In these 80 families 385 children were born, 203 males and 182 females. In these tuberculosis appeared in 98 males and 96 females; and there died from this disease in childhood, 21 males and 16 females, while 84 males and 70 females remained apparently healthy. From these figures the conclusion is reached that the effect of paternal inheritance on males is to cause pulmonary tuberculosis to appear at an earlier age than in the parent and to reduce the constitutional resistance of the individual to the disease, while in females also it causes an earlier manifestation of the disease, but if anything, increases their resistance to it. The influence of tuberculous mothers, on the other hand, on their male offspring, is to increase the tendency to rather copious bleedings from the lungs, a circumstance that is not noticeable in females.

THE ETIOLOGY OF YELLOW FEVER.

The belief is growing that insects are important, even essential factors in the etiology of certain diseases. That malaria is inseparably connected with a mosquito that acts as an intermediate agent in the dissemination of the disease, has been proved definitely by suitable experiments, and the mosquito theory of malaria is in accord with the epidemiologic facts of the disease. Certain observations in the American typhoid camps of the Spanish-American War have brought the fly to the fore as a probable and dangerous carrier of typhoid fever. For some time past great interest has been taken in the etiology of yellow fever, and since the recent studies of Reed, Carroll and Agramonte on the rôle of the mosquito in this disease,[1] additional data have been awaited with much eagerness. Important additional evidence of the etiologic importance of mosquitoes—Culex fasciatus, Fabr.—in yellow fever is given in the paper presented by these investigators at the recent Pan-American Medical Congress in Havana, and published in this issue of THE JOURNAL. A few comments on this important paper may be ventured. At first thought one might be tempted to characterize the experiments carried out on the human beings as unwarrantable, but as we are assured that everything was done with the full consent and full knowledge of the nature of the experiments on the part of the non-immunes who placed themselves at the disposal of the experimenters, there can be no adequate reason for complaint on this score. Whatever the opinion concerning this phase of the experiments, it in no way modifies the scientific value of the results. The non-immunes that allowed themselves to be bitten by mosquitoes that previously had sucked the blood of yellow fever patients, as well as the persons who slept in the "Infected Clothing and Bedding Building," seem to have submitted themselves unreservedly to the requirements of the experiments. There are examples here of unselfish devotion to the cause of humanity and of science.

---

[1] Lancet, Nov. 10, 1900, p. 1335.

The results of the experiments support the mosquito theory of yellow fever. The data are as yet rather scanty for the establishment of absolute conclusions with regard to all phases of the etiology of this disease, the specific cause of which is unknown. It seems well settled, however, that mosquitoes that have fed on the blood of yellow fever patients may transmit the disease to non-immunes. No one will doubt the far-reaching importance of this demonstration! Some evidence is also brought forward to show that exclusion of the intermediate host for the parasite of yellow fever renders the disease intransmissible. The results of experiments with infected clothing and bedding must be viewed in this light. The statement that "disinfection of articles of clothing, bedding, or merchandise, supposedly contaminated by contact with those sick with this disease—yellow fever—is unnecessary," seems to go a little further than the facts warrant; for it has not yet been shown that the intermediate host might not pick up, as it were, the parasite of the disease from these contaminated materials. In the future it is possible that the prevention of yellow fever may be reduced to the protection of both sick and well from the bites of Culex fasciatus, and to the destruction of this mosquito, should it be found to be the only intermediate host capable of transmission of the disease.

THE PATHOLOGY OF AKROMEGALY.

Lesions of the pituitary body have been found in so large a proportion of cases of akromegaly in which post-mortem examination has been made that, according to the prevailing view, the symptoms of the disease are to be attributed to such lesions, the pituitary body being believed to exercise some influence—of an inhibitory nature—on the growth and development of the skeleton, and the removal of which permits of hypertrophy of the bones. Some enlargement of the pituitary body has been observed also in cases of myxedema and cretinism; while, on the other hand, tumors of the pituitary body are sometimes unattended with symptoms of akromegaly and, as has been indicated, no change in the pituitary body has been noted in some cases of akromegaly, this body having been entirely wanting in at least one case. In many, further, the thyroid gland has been enlarged; and the thymus has been persistent in some. Enlargement of the spleen, hypertrophy of the breast, and changes in the pancreas and the ovaries—together with menstrual derangement—have also been occasionally observed. In view of the facts, therefore, the question can reasonably be asked whether the change in the pituitary body may not be merely one part of the morbid anatomy, in turn giving rise to certain symptoms peculiar to itself, and, together with the other changes due to some as yet undiscovered underlying common cause.

To the growing list of cases of akromegaly presenting lesions of the pituitary body, Mendel[1] adds another, in which this gland was the seat of a sarcoma. The patient was a woman, 29 years old, in whom characteristic symptoms had been present for six years. In addition to the typical changes in the skeleton—the hyperplasia of the supraorbital margins, the malar arches, the lower jaw, the hands and feet—there was temporal hemianopsia, with enlargement of the thyroid gland, abolition of the knee-jerks, and amenorrhea. Subsequently there developed also intense frontal and occipital headache, and severe and at times incoercible vomiting. Remissions occurred from time to time, but these were attended with polyphagia and polydipsia. The breasts were enlarged, notwithstanding the general emaciation. Treatment with a preparation of pituitary gland was without avail. Death occurred suddenly in an attack of pain. On post-mortem examination a tumor rather larger than a walnut was found at the base of the brain, in the region of the optic chiasm. The growth measured 6.5 cm. in its greatest width, and 3.5 cm. in its greatest thickness, and it was of soft, spongy consistence and grayish-red in color. On histologic examination, it proved to be a large, round-cell sarcoma, with connective-tissue septa in places, in part in process of myxomatous transformation. The tumor extended forward into the substance of the orbital temporal convolutions. On section, it was found that posteriorly it virtually occupied the third ventricle, extending symmetrically from below and the middle line into the greatly dilated lateral ventricles. The head of the caudate nucleus, a large part of the fibers of the knee of the corpus callosum, as well as both optic thalami, and the substance of the orbital temporal convolutions, were involved in the growth. The optic tracts were reduced to fine threads and were displaced by the tumor. The chiasm was represented by a thin band, resembling connective tissue. The sella turcica was excavated and enlarged in all directions. Its walls were thinned anteriorly as well as posteriorly, but the bone was not invaded by the new-growth. There was no trace of the normal structure of the pituitary body. The thyroid gland was greatly enlarged from the presence of colloid material; the thymus gland was persistent; the spleen was enlarged and softened; the right ovary was cystic; the mammary glands were excessively developed. Apart from uniform increase in size, the bones of the skeleton presented no abnormality; and the heart, lungs, liver and kidneys also were normal.

NEW FIELD FOR TRAINED NURSES.

From an editorial paragraph in a British contemporary[1] we learn that one of the latest fads over there is having trained nurses for pet dogs. We have heard of women nursing dogs before, but this is the first notice of that function of trained nurses. There is so much said nowadays of the high ideal, etc., of the nursing profession that it is something of a shock when this evidence comes to hand that, to some extent at least in Great Britain, it is literally "going to the dogs." So far as known this bestial fad has not appeared as yet in this country, though a combination of zoophile and anglomaniac possibly exists that may introduce it.

DIPLOMA-MILL GRADUATES IN MICHIGAN.

The Armstrong diploma-mill products located in Michigan are making a fight for their professional existence, and are unscrupulously using all means to that end. As an example of their zeal a circular explaining itself as "an appeal to the medical profession of the state" has been sent out seeking signers for a petition to the governor and legislature asking that the law be amended in their behalf. One argument used by them is that the present law will be declared unconstitutional by the U. S. Supreme Court. "Having a knowledge of all this," says their spokesman, "we do not think it wise or prudent to open up Michigan once more as a dumping ground for quacks." Whatever the judicial opinion may be on technical points of the law, the anxiety of these fellows whose medical qualifications were derived from the convicted fraud Armstrong and his quack manufactories to keep Michigan from being a "dumping ground" is sufficiently peculiar and conspicuous to be noteworthy.

EXPERIMENTAL TRANSPLANTATION OF INTESTINE INTO THE STOMACH.

Experimental operations on the gastro-intestinal tract have been long, a favorite field for the investigator. The contributions to experimental intestinal surgery by Senn have exercised a marked stimulus on the workers in this field. The purpose of these investigations is an exceedingly practical one, namely, to lay a sound foundation for the complicated and difficult surgical measures necessary to meet the numerous and varying indications presented in curative abdominal surgery. Recently Reerink[1] undertook to demonstrate whether large defects in the anterior wall of the stomach could be filled satisfactorily with implanted pieces of the intestine. For this purpose he excised a segment of the colon in dogs, reunited the divided ends of the colon, and sutured the piece of intestine, after laying it open, into a corresponding defect in the anterior wall of the stomach. After the first two or three mishaps he succeeded in securing firm fibrous union of the implanted intestine to the walls of the stomach. The final fate of the implanted piece has still to be determined by new experiments. Contingencies are easily imagined in which this procedure may be of advantage in human surgery—after excision of tumors and of ulcers of the stomach, for instance. In few fields is the ingenuity of the experimenter more quickly rewarded by increased facilities for expansion of surgical intervention than in experimental surgery of the abdomen.

MEMBRANOUS ANGINA DUE TO OTHER MICRO-ORGANISMS THAN DIPHTHERIA BACILLI.

It is by no means always safe to make a diagnosis of diphtheria from the presence of so-called false membrane in the throat or upon any other mucous or epithelial surface, as it is perfectly well known clinically, and has been demonstrated bacteriologically, that such a condition may be due also to the activity of other micro-organisms than diphtheria bacilli, and even without the intermediation of bacteria; for instance, as a result of the action of hot liquids or corrosive poisons or vapors. Thus, it has been shown that the angina of scarlet fever is not dependent on the activity of diphtheria bacilli, but is probably due to that of streptococci, and the oidium albicans is capable of giving rise to depositions of thrush that may cause some doubt in diagnosis. In addition to these, it is pointed out by Dr. W. G. Bissell[2] that the micrococcus of sputum-septicemia may cause the formation of a membranous deposit in the throat indistinguishable clinically from that of diphtheria. In the experience of the Bureau of Bacteriology of the Buffalo Department of Health there has been no fatal case of membranous angina due to the oidium albicans, although several cases of this character, due to streptococci and the micrococci of sputum-septicemia, have been observed. It is thought that these disorders, if at all communicable, are less so than diphtheria. These facts emphasize the necessity, already appreciated, of submitting to bacteriologic examination material from diseased throats, and governing the stringency of isolation in accordance with the identity of the microorganisms present.

MARRIAGE LEGISLATION.

In no less than three states at the present time enactments regulating marriage are before the legislatures, and apparently with some prospects of success. They are alike in their general provisions, prohibiting the union when one or the other of the candidates for matrimony is not physically sound, is subject to insanity, epilepsy, tuberculosis or other hereditary disease. In one state the proposed law apparently prohibits marriage if one or both the parties are members of a family tainted with these disorders, and in one there is an age limit established for women at 45 years, according to the newspaper reports of the bill. This probably is the same provision as is contained in a similar enactment in an eastern state in which marriage was permitted after the presumed reproductive period had been passed, and not a prohibition of marriage after that age. The difficulty with these and any similar laws is the impossibility of executing them; there may be a heavy penalty for the forbidden marriage in one state, but the ceremony can be legally performed a few miles away in another, and then the relations must be recognized as legal everywhere within the United States. So long as there is any part of the country where such laws do not prevail, they can be rendered ineffective. There is still another objection—if legal marriage is made difficult, illegal births become more frequent and illegitimacy may be added to degeneracy in a considerable portion of the population, a result certainly not to be desired. It would be an excellent thing could we prevent the propagation of diseased heredity. The sum of human happiness would be increased if fewer people were almost inevitably predestined from birth to suffering and disease, but the question is how far can we prevent it by law with our present social and political institutions. The experiment seems likely to be tried, possibly on an extensive scale, and the results will be of interest.

USE AND PRESCRIPTION OF ALCOHOL.

The Woman's Christian Temperance Union has issued a circular to physicians asking their aid "in the efforts being made to remove as far as possible all tendencies and temptations toward the formation of the drink habit." It particularly requests physicians to warn patients against the home prescription of alcohol and the use of proprietary medicines containing alcohol and other narcotic drugs. The circular would, however, be more effective with the medical profession generally did it not imply in other statements it contains, that alcohol has no value under any conditions as a medicine. There are, we know, physicians of acknowledged reputation who hold this view, but there is a much larger number, most of them, we believe, in full sympathy with the objects of the Woman's Christian Temperance Union, who maintain that it has its uses and that in certain morbid conditions nothing can well supply its place. These views are honestly held by, we believe, the great majority of the medical profession, and are perfectly compatible with the strictest temperance principles. A conscientious physician, holding that alcohol is a poison, but like many other poisons useful as a medicine under certain circumstances, would employ it as he would other poisons with all precautions against arousing appetite; he might even consider the dangers of alcohol to contraindicate its use in certain cases, notwithstanding its therapeutic value. The W. C. T. U. would have done better, we think, to have recognized the possible value of alcohol as a medicine, or at least the difference of opinion in regard to it, while not abating in any way the general condemnation of its indiscriminate prescription for ailments when it is not needed, and they would have then had the unqualified support of a vast majority of the medical profession.

SERUM TREATMENT OF MALIGNANT TUMORS.

Wlaeff immunized geese with blastomycetic organisms obtained from malignant tumors by Curtis, Plimmer and Sanfelice. He then subjected some 26 patients with carcinomas and other tumors to treatment with the serum of the immune geese.[1] The results are reported to show that the serum, which for some reason not stated is called anti-cellular. is quite harmless and free from danger; there forms a swelling at the seat of injection; the tumor itself swells up; later it diminishes in size, and eventually after repeated injections it may become encapsulated; regional lymphatic glands return to their normal size in case they are the seat of inflammatory enlargements, and those that are invaded by metastases diminish in volume. In favorable cases it is claimed that the serum may cause diminution in the size of the tumor and arrest of its evolution. Some abatement follows serum injections, also in advanced cases with ulceration and metastases. Among the general effects of the serum are noted: Some rise in temperature, shooting pains in the tumor, increase in strength and weight, return of sleep and appetite, marked leucocytosis, and occasionally an urticarial eruption. Seven to twelve cubic centimeters are injected subcutaneously in the thigh, the injections being repeated every 5 to 8 days. Wlaeff regards this treatment as the most valuable we now have. Whether a complete cure is obtainable by his method remains to be seen. At present he is working with asses, hoping to thus obtain a more efficacious serum. It is safe to say that this method as yet rests on a rather insufficient scientific basis. It is true that Curtis, Plimmer, and Sanfelice isolated blastomycetes from human tumors; and Wlaeff as well as Sanfelice claim they have produced true tumors in animals by injection of some of these organisms; but this claim has not been generally accepted, the common opinion being that the resulting growths are of inflammatory origin. In some of Wlaeff's experiments, however, epithelial proliferations with much similarity to adenoma are recorded, concerning the nature of which, whether inflammatory or truly neoplastic, there seems to be room for well-founded doubt. Wlaeff says that his serum cures infected animals, whereas the controls die from "tumors" and cachexia. It is also rather singular that serums produced by injections of different organisms from different kinds of tumors should have similar action on various tumors in human patients. The "anti-cellular" serum lacks the specificness, which is expected from analogy with other sorts of anti-serum. Naturally, the results here referred to must be confirmed by others before they may be accepted as at all decisive. They show, however, the direction in which the blastomycetic theory of malignant tumors is leading investigation.

---

CALIFORNIA'S PLAGUE LEGISLATION.

The Journal has already editorially noticed some extraordinary recommendations in the recent message of the Governor of California. These have since borne fruit in a bill offered in the state legislature which makes it a felony for any person "to publish by any writing or printing that Asiatic cholera or bubonic plague exists or has recently existed within the state unless the State Board of Health thereof has first determined such to be the fact and has entered a record of such determination upon the minutes of such board." This proposed law would therefore require a physician recognizing one of these diseases to suppress the fact until the State Board of Health chooses to investigate the matter and have the diagnosis regularly entered on its minutes, a procedure that would be eminently incompatible with the interests of the public as regards precautions against the spread of the disease. It is hard to understand how any rational legislator can fail to see this aspect of the case, and should the measure pass it can only be ascribed to a wave of acute imbecility involving the legislature. The bill as it stands is, as a California paper expresses it, "An act to make perjurers out of reputable physicians under penalty of being felons if they tell the truth." It is satisfactory to see that some newspapers in that state take a sensible course in regard to the matter, in spite of the apparent unreasoning craze that seems to have taken possession of the authorities. Unless the people of California come to their senses about the plague they may find themselves more seriously involved than they expect. The San Francisco Board of Health is undoubtedly doing what it can to check the spread of the plague, and so far with much apparent success, but there can be no assured confidence that it will be entirely stamped out as long as the state authorities adopt the ostrich policy of denying its existence, and the presumption exists that their action is in accordance. Such legislation as is proposed and the course of Governor Gage and the San Francisco press will do the state much more harm than good. What this country and other countries wish to know is that the California authorities are doing what they can to eradicate the pest. So far they have apparently done nothing but protest, and that altogether too much.

THE RELATION OF MALARIA TO THE GEOGRAPHIC DISTRIBUTION OF THE MALARIA-BEARING MOSQUITO.

Grassi asserts that the geographic distribution of the genus Anopheles, the mosquito of malaria, in Italy coincides with that of malaria. He thinks that a like coincidence will be found the world over. In the first number of the *Journal of Hygiene*, a new publication from Cambridge, England, founded for the purpose of the publishing in the English language of original work in hygiene, Nuttall, Cobbett and Strangeways-Pigg show quite clearly that Grassi's claim has no general application; for they have found Anopheles in many parts of England "where there is no record of malaria having previously existed, and where there is certainly no malaria to-day." Celli also has found Anopheles in healthy places in Italy in which there has never been malaria. The disappearance of malaria from Great Britain consequently does not depend upon the extinction of mosquitoes capable of harboring the parasites of malaria. The English investigators mentioned found Anopheles most numerously in low-lying land with stagnant water, in every way suitable for their habitat, and corresponding to former malarious districts. The disappearance of malaria is therefore attributed to several causes other than extinction of Anopheles, such as reduction of the numbers of this mosquito due to drainage of the land, reduction of the population by emigration, and possibly the use of quinin. Emigration would reduce the number of infected persons and thus lessen the source of infection of Anopheles, and the same result would follow the use of quinin, which checks the development of parasites in the blood. Probably drainage was the most efficient cause; at all events the older authors largely ascribed to it the disappearance of ague. As the geographic distribution of Anopheles is wider than that of malaria, it would seem as if an essential factor in the etiology of malaria is the number of Anopheles in any one place. The occurrence of Anopheles in non-malarious districts explains the occasional development of malaria in unexpected places without refuge to the assumption that malaria-bearing mosquitoes have been imported, as a malarious patient might well infect the local insects. Investigators studying malaria in various parts ought to follow the lines laid down in this report and search as carefully for Anopheles in non-malarious as in malarious regions. Only by such work is definite knowledge obtainable in regard to this phase of malaria and whether other blood-sucking insects may be the hosts of the malarial parasites.

THE DISSEMINATION OF THE TUBERCLE BACILLI FROM COWS IN COUGHING.

Inasmuch as the lungs are the most common seat of tuberculosis, and infection occurs through the dissemination of the discharges of the morbid lesions, the sputum constitutes the most frequent medium of communication. It has been shown that the milk of tuberculous animals may assume this rôle, even when the mammary gland and the nipples are not the seat of the disease; and occasionally infected flesh used as food, and imperfectly cooked, may act in a similar way. Human beings, however, are considered the worst offenders in this connection, by reason of the pernicious practice of promiscuous spitting, although it has been shown that tubercle bacilli may be contained in the fine particles ejected in the act of coughing. While the lower animals can not be charged with the offense of spitting, they do, however, cough; and it has, perhaps, not been sufficiently appreciated that in this way they may additionally aid in the spread of tuberculosis. That such a mode of dissemination is at least possible is demonstrated by some experimental observations made by Dr. M. R. Ravenel,[1] in the laboratory of the State Live-Stock Sanitary Board of Pennsylvania, which illustrate, besides, one of the beneficent objects to which intelligently administered boards of this character can devote themselves. By means of an ordinary nose-bag, near the bottom of which was arranged a shelf of sterilized soft pine wood, and kept in place for varying periods of time, the smallest particles ejected by tuberculous cows in the act of coughing were caught, then removed with a platinum needle to a cover-slip and examined microscopically. In this way it was possible to invariably demonstrate tubercle bacilli in the bronchial secretion from five tuberculous cows—twenty times in thirty-four examinations. In some instances, in which microscopic demonstration failed, inoculation experiments yielded positive results. As is pointed out, the danger to human beings from such atomized sputum is confined to those who come into contact with the animals, but it is much more constant and more pronounced for other animals in the same stable.

Medical News.

CALIFORNIA.

Dr. Luther M. Powers was re-elected health officer of Los Angeles, January 29.

Dr. Myrtle Aplin, East Highlands, formerly house physician at the Lane Hospital, San Francisco, has been appointed resident physician at the State Insane Asylum at Napa.

COLORADO.

New Medical Bill.—Dr. Benjamin F. Jefferson, Steamboat Springs, senator from Routt County, has introduced a bill into the senate which places the practice of medicine in the state entirely under the control of the State Board of Medical Examiners, which consists of five regulars, three homeopaths and one eclectic, to be named by the governor.

A Glenwood Springs physician set at defiance orders issued by the mayor to report to the municipal authorities all cases of contagious disease, and treated five cases of smallpox, reporting later to the secretary of the State Board of Health that he had the patients under supervision. The local board of health has instituted legal proceedings against him.

Prize Essay on the Dangers from Quackery.—The Colorado State Medical Society offers a prize of $25 for the best essay, deemed worthy of the prize, pointing out the dangers to public health and morals, especially to young persons, from quackery as promulgated by public advertisements. The competition is open to all. Essays must be type-written, in English, and submitted before May 15. Each essay must be designated by a motto, and accompanied by a sealed envelope, bearing the same motto, and enclosing the name and address of the author. The essay receiving the prize will become the property of the Society for publication. Others will be returned on application. Essays should be sent to the Literary Committee. room 315, McPhee Building, Denver, Colo.

ILLINOIS.

The Use of the Title "M.D.," or "Dr." by those who have not first obtained a license to practice medicine under the laws of the state is prohibited in a bill introduced by Representative Jones, of Cook County, February 6.

Medical Legislation.—If Senator Stubblefield's amendment which provides that nothing in the act shall be construed to apply to any person who ministers to or treats the sick or suffering by massage or by mental or spiritual means without the use of any drug or material remedy prevails, the new medical bill will be detrimental to all. The word "massage" will let down the bars to a great horde of quacks and charlatans who will work the gravest injury to public health and demoralize the medical profession. A committee has been appointed by the Illinois State Medical Society to combat the amendment, and is now conducting a most active campaign against the proposed measure. The co-operation of the sixty medical societies throughout the state has been invited and physicians all over the state are enlisted in the cause and are using all endeavor to defeat the bill.

Chicago.

Dr. William H. German will continue the work of the late Dr. Charles W. Purdy, of which he has been in charge for some months past.

Medical Students in parties of ten are being taken three times a week, by health department officials, to the Isolation Hospital to learn more of smallpox by actual observation of patients in that institution.

Wesley Hospital has received two donations of $5000 and $1000 from donors whose names are not to be announced until the dedicatory exercises of the new hospital, in May. The donations thus far received by the hospital amount to $101,000.

Hospitals benefit to the extent of $50,000 each by the generosity of the late Albert A. Munger. The institutions named are the Women's and Children's Hospital, the Chicago Foundlings' Home, the Chicago Nursery and Half-Orphan Asylum and the Home for Incurables.

A Hindu victim of the "International Medical College" has made an appeal to the world to prove his genuineness as a physician. He paid for his diploma, but his practice suffered when the president of the "college" was convicted of fraud. He supplements his appeal by testimonials, protests and other documents signed by high officials of India.

Health Conditions.—In every respect, except as to influenza, public health conditions continue to be satisfactory. The weekly bulletin of the health department announces that the threatening indications of the first three weeks of the year, during which the death-rate was 16.5 per 1000, as against 16.1 during the corresponding period of 1900, have subsided during the last three weeks, in which there were 125 fewer deaths than last year and a change in death-rates from 15.5 per 1000 in 1900 to 14.2 this year. Typhoid fever, diphtheria, scarlet fever, bronchitis and pneumonia death-rates are unusually low for the season of the year and remarkably so in the presence of influenza.

Scarcity of Ripe Vaccin.—Subsidence of the smallpox outbreak is especially fortunate in view of the scarcity of ripe vaccin. This scarcity has led producers to furnish lymph that has not been exposed to the action of the glycerin long enough to sterilize it properly. Such lymph produces very severe symptoms and the old-time "sore arms" of the vaccine "point." So serious had this become that school vaccination was suspended temporarily by the commissioner of health on February 8. It is expected to resume in a short time—as soon as the daily examinations in the laboratory show that the lymph is in proper condition. The emergency is not deemed grave enough to warrant the use of lymph which causes so much useless suffering and disability. Added severity of vaccination adds nothing to its protective power against smallpox; it is simply an evidence of impurity in the lymph—impurity which is removed by the action of the glycerin in from fifty to sixty days.

INDIANA.

Dr. Joseph L. Bell, Richmond, has been appointed assistant-surgeon in the army, and is ordered to report at Fort Crook, Neb.

An anonymous benefactor has added $10,000 to the $4000 already subscribed for the projected Union Hospital at Crawfordsville. This donation will assure the establishment of the hospital.

Hospital for Inebriates.—The committee on inebriety, of the State Board of Medical Registration, met at Indianapolis, February 1, and prepared a bill asking for an appropriation of $100,000 to found a state hospital for inebriates.

"Christian Science."—Senator Wood, of Lafayette, is making a fight in the legislature against "Christian Science." His bill makes it a felony for one having the care of a dependent person to withhold medical attention from such person on account of "Christian Science," death resulting from such withholding.

IOWA.

Smallpox is reported in more than forty localities in the state.

Dr. Benjamin W. Searle has been appointed pension examiner at Ottumwa.

Dr. Benjamin F. Campbell, Burlington, has been appointed physician of Des Moines County, vice Dr. Albert C. Zaiser, resigned.

---

[1] Proceedings of Path. Soc. of Phila., N. S., iv, No. 2, p. 26.

The new coroner for Clinton County, to fill the position made vacant by the death of Dr. Charles Osborn, for the unexpired term, is Dr. Schuyler C. Hamilton, of Lyons.

Dr. Charles R. Russell, Ottumwa, has been reappointed physician of Wapello County, and Dr. E. A. Shaafe, also of Ottumwa, physician for three townships in the county.

Dr. Joseph A. Scroggs, Keokuk, has retired from the State Board of Health and the State Board of Medical Examiners, February 1, after serving for seven years, the latter part of the time as president.

MARYLAND.

Dr. William Osler, Baltimore, has given $1000 to the endowment fund of the library of the Maryland Medical and Chirurgical Faculty.

Dr. Lindsay Peters, formerly an assistant to Dr. Howard Kelly, has been made one of the resident staff of the insane department of Bayview Hospital, Baltimore.

Dr. William Whitridge, Baltimore, was elected president of the Maryland Society for the Prevention of Cruelty to Animals, at the twenty-eighth annual meeting, held January 19.

Dr. Thomas B. Owings, health officer of Howard County, recently discovered three cases of smallpox at Hanover Switch, near Elkridge. Many persons had been exposed and the cases had not been reported. A general outbreak is feared.

MICHIGAN.

An unlicensed Practitioner, of New Troy, has been arrested at the instance of the officers of the Berrien County Medical Society, for practicing in violation of the state law.

Dissection material in quantity sufficient to supply the needs of the students of the University of Michigan is difficult to secure, as the number of students has increased disproportionally with the number of unclaimed bodies of those who die in public institutions.

January Health of Michigan.—The report of the secretary of the State Board of Health shows that in the month of January, compared with the average in the ten years preceding, typhoid fever and smallpox were much more prevalent, and diarrhea, intermittent fever, erysipelas, remittent fever, measles, cerebrospinal meningitis and whooping-cough were less prevalent than usual.

New Medical Registration Board.—The governor appointed, on January 31, a new state board of medical registration, the appointments of the previous board having never been confirmed. As the board now stands, only four of the ten members hold over. It is composed of the following: Drs. Joseph B. Griswold, Grand Rapids; George E. Ranney, Lansing; Walter H. Sawyer, Hillsdale; Austin W. Alvord, Battle Creek; Henry B. Landon, Bay City, and five from other schools of medicine.

MINNESOTA.

Dr. David N. Jones, Gaylord, has been appointed a trustee for the state hospitals for the insane.

State Medical Examiners.—The governor has appointed Dr. Albert G. Stoddard, Fairfax; Dr. William Davis, St. Paul, and Dr. Albert F. Groves, Brainerd, members of the board.

Sanatarium for Consumptives.—A bill was introduced in the senate February 2 providing for a state sanitarium in the pine woods, for the treatment and cure of consumptives. It carries an appropriation of $150,000, with an annual appropriation of $50,000 for maintenance.

Osteopathic License.—A bill was introduced in the senate, February 2, providing that graduates of any legally incorporated school of osteopathy, may, on presentation of their diplomas and the payment of a fee of $2 to the secretary of state, secure a certificate authorizing them to practice osteopathy in the state. A penalty of from $50 to $100 is provided for practicing without such license, or obtaining one by fraud. Osteopathy is declared not to be the practice of medicine within the meaning of the state medical law.

MISSOURI.

Non-resident physicians are prohibited from practicing medicine in the state by proxy, by a bill passed by the state senate, February 5.

A State Hospital is proposed for the benefit of the sick poor of Missouri who now are sent to St. Louis for treatment, thus imposing a disproportionate burden on the municipal finances.

Under the new law Dr. James K. Graham, St. Joseph, has been appointed physician for the newly organized county board of health, and Dr. Carl Bitter, St. Charles, for that of St. Charles County.

The Smallpox Bill.—This, the first bill passed by the state legislature, provides for the creation of a county board of health in each county, which shall appoint a reputable physician. These county boards shall have the same powers and authority as are already given to the State Board of Health, within their respective limits, exclusive of incorporated cities and towns, regarding quarantine regulations and the prevention of the spread of communicable diseases therein.

NEW YORK.

Dr. Eugene J. Hanratta, Watervliet, has been reappointed city physician.

Dr. John C. Brown, Albany, has been appointed penitentiary physician, vice Dr. Charles H. Richardson, resigned.

A Smallpox Expert.—The State Board of Health has sent a smallpox expert to tour the state as an inspector, visiting the various places where smallpox has developed, and giving such advice to the local health authorities as may be needed.

Consumptive Hospital.—A bill has been introduced in the senate appropriating $100,000 to apply on the construction of the State Hospital for Incipient Consumptives. An appropriation was made some time ago, and if this bill passes, there will be enough money available to build a hospital with accommodations for 100 patients.

A Practitioner of Medicine.—According to an amendment to the Bell bill, approved by the state and New York City and County Medical associations a practitioner of medicine is one "who shall give treatment to any other person by the use of any remedy, agent, or method whatsoever, whether with or without the use of any medicine or instruments, or other appliances for the relief or cure of any wound or fracture, bodily injury or infirmity, physical or mental disease."

Buffalo.

Dr. Harry Mead has tendered his resignation as captain and assistant-surgeon of the Sixty-fifth regiment, N. G., N. Y.

Dr. Frederick W. Barrows, professor of histology and biology, at the University of Buffalo, was elected president of the New York State Association of Science Teachers at its recent meeting held at Rochester.

Dr. Eugene Wasdin, U. S. Marine-Hospital Service, now stationed at Buffalo, has been tendered by the Italian government the cross of officer of S. S. Maurizio et Lazzaro in recognition of his services in verifying and confirming the Italian studies and discoveries regarding the nature of yellow fever.

Charges Against Fitch Hospital.—Recently one of the daily papers made sensational charges against the superintendent and house physicians of the Fifth Accident Hospital. The hospital committee of the institution has found the charges without foundation, but the trustees of the Charity Organization Society of which the hospital was a branch, by resolution, welcome an inquiry by any responsible public authority, and charge and instruct all committees and employees of the society to give every facility for the full discovery of the facts and to render all assistance in their power.

New York City.

Home for Male Cancer Patients.—The Dominican sisters, who have in charge the recently established St. Rose's Free Home for Incurable Cancer Sufferers, have taken steps toward raising $40,000 to establish a similar home for such male patients.

Insanity Laws.—The New York Neurological Society and the State Charities Aid Association have each passed resolutions condemning any amendment to the state insanity laws, which would do away with the provision that the medical member of the commission shall have had five years' actual experience in the care and treatment of the insane.

Testimonial to Prof. Quinlan.—A complimentary dinner was tendered to Dr. Francis J. Quinlan, January 31, at which a loving-cup suitably inscribed was presented to him. Many distinguished members of the profession were present, and representatives from the various hospitals and medical schools. The dinner was given under the auspices of the New York Celtic Society.

Bellevue Hospital Abuses.—The report of the medical board to Commissioner Keller, shows that during 1900 24,300 patients were admitted to the hospital, 11,370 of which were ambulance cases. The five other principal hospitals of New York City cared for 2300 less patients than Bellevue Hospital alone. The report recommends that the insane be placed in charge of two well-qualified, salaried physicians who shall be held responsible for the condition of every one of their patients. Pupil nurses are not considered fitted for work in the insane pavilion. Special stress is laid on the absence of proper discipline and of a system whereby all nurses are held strictly and directly accountable to the superintendent of the hospital. The present system of poorly-paid and poorly-housed helpers is found to be a source not only of discomfort but of actual disease.

OHIO.

Dr. Harry H. Hatcher, Dayton, has succeeded Dr. John C. Reeve, Jr., as district surgeon of the Erie Railway.

Dr. John C. Larkin, Hillsboro, has been appointed local surgeon for the Baltimore and Ohio Southwestern Railroad.

Dr. and Mrs. Samuel W. Kelley, Cleveland, sailed January 31 on the *Augusta-Victoria* for a seventy-day cruise of the Mediterranean.

Dr. Caroline B. Culver, Sandusky, has been appointed a member of the medical staff of the State Hospital for the Insane at Massillon.

Lakeside Hospital, Cleveland, has received $10,000 from Mr. L. C. Hanna, to complete the erection and equipment of a ward for communicable diseases.

PENNSYLVANIA.

New Insane Hospital.—Representative Calder, of Harrisburg, on recommendation of the State Board of Charities, has introduced a bill in the house appropriating $500,000 for the construction of a new Pennsylvania state lunatic hospital in Harrisburg. It is hoped that if the appropriation is made the building now located there will be torn down and other buildings erected, 2 for convalescents, and 2 for destructive and dangerous patients. The sum of $350,000 will be required to erect these buildings, while the remainder of the amount is required for additional buildings.

Philadelphia.

A gift of $1000 has been given the Episcopal Hospital.

Medical Inspection.—During January, the medical inspectors acted on 457 cases of diphtheria, 329 of scarlet fever, 352 of typhoid fever, 210 of tuberculosis, and 1 case of smallpox.

Friction at Germantown Hospital.—Owing to friction between the board of managers and the staff of regular physicians of the Children's Hospital of Germantown, the latter have withdrawn as a body and left matters in the hands of the homeopaths, who are in full control of the institution.

"Knockout Drops."—So common has it become to report deaths due to "knockout" drops and other poisons that Coroner Dugan has been urging the enforcement of the laws regarding the sale of poisonous drugs, and of preventing their sale unless on physicians' prescription.

Antivaccination Bill.—A special meeting of the board of health was held February 11, to protest against the antivaccination bill recently introduced in the legislature. The immunity from smallpox in this city at this time has been attributed largely to the enforcement of the existing laws on this subject. Only a few cases have been discovered during the year, and these ordinarily occurred among negroes who had come in contact with others from infected districts of the South.

TENNESSEE.

Dr. J. S. Dye, Chattanooga, has returned after several months spent in study in Vienna.

Chattanooga is to have an ambulance and an isolation hospital, the latter being accessible only by a special pest-boat.

Dr. Howard K. Edgerton, Lebanon, sustained a fracture of both legs, February 1, by a tree falling across his buggy while he was driving.

The Nashville Board of Health reorganized January 28 and elected Dr. William G. Ewing, president. Dr. William Bailey is the new member.

Dr. Walter S. Nash, who sued the City of Knoxville for more than $1000 for services in the treatment of smallpox, has had his claim disallowed by Chancellor Shields.

The House of Representatives has again refused to give the State Board of Health power to control contagious diseases, where county and city officials fail in their duty. Efforts were made to exempt the cities, and otherwise make the bill acceptable over the opposition, but without avail.

UTAH.

Dr. Harry N. Mayo has been appointed to succeed Dr. Hyrum A. Anderson as physician of Salt Lake County.

Efficacy of Vaccination.—The Salt Lake Board of Health statistics show that from October 1 to December 31 there were 314 cases of smallpox in Salt Lake City, of which 291 were persons who had never been vaccinated. Of the remaining 23 cases 14 had not been vaccinated for more than twenty years.

Anti-vaccinationist Victory.—A bill introduced into the house of representatives, making it unlawful for any board of health or other board, having police powers or otherwise, to compel vaccination, or to make it precedent to the attendance of public or private schools recently passed by a vote of 37 to 6

The State Board of Medical Examiners, in the biennial report, states that during the two years ended Dec. 31, 1900, 42 persons were examined, 38 of whom received licenses to practice. The suggestion is made that the act of the legislature regulating the practice of medicine be so amended that the board can issue certificates from other recognized state boards of medical examiners, who would accept the state board's certificates in the spirit of reciprocity.

The medical men of Ogden have entered into a combination against irregular practitioners. At a joint meeting of the two medical societies, January 18, resolutions were passed stating that the members will sign no death certificates where the dead person was treated by a non-graduate or an irregular practitioner. No specific class is mentioned, but it is understood that the doctors intended the resolutions to apply to christian scientists, faith healers and similar practitioners.

VIRGINIA.

Protest Against License.—The physicians of the state have inaugurated a movement having for its object the abolition of the special license fee for physicians in the state. At present the physician pays a license fee to the city and another to the state, graded to the extent of his practice. In addition, he pays registration fees, income tax, etc.

Physician Indicted.—A practitioner, who, it is claimed, has never taken the state examination, although he has practiced in Newport News for several years, has been indicted by the grand jury for practicing as a physician and surgeon without securing a certificate from the State Board of Medical Examiners.

WISCONSIN.

Dr. John Madden, professor of physiology, Milwaukee Medical College, has resigned.

Dr. John Phillips has been appointed special physician in charge of smallpox patients in Stevens Point, at a salary of $15 a day.

Dr. William B. Lyman, superintendent of the State Hospital for the Insane, at Mendota, has resigned and will return to practice in Eau Claire.

Dr. Arthur L. Payne, Eau Claire, has been awarded damages of $5300 against parties who claimed that the plaintiff had been guilty of fraud and deception in his treatment and report of a case.

CANADA.

Leprosy in New Brunswick.—According to the annual report of the Minister of Agriculture of the Dominion Government, at the Lazaretto at Tracadie, N. B., there were 4 deaths during the year among the lepers, and 3 new admissions. At the present time there are 20 lepers in the institution, 13 males and 7 females.

Counter Prescribing.—This has been a much-talked-of subject among the druggists of Toronto during the past week or two. Over a dozen have recently been in the police court, at the instance of the detective of the Ontario Medical Council, and those of them whose cases have been heard have been fined $25 and costs or thirty days in jail without hard labor. This has been due to violations of the medical act, and is commonly called "counter prescribing."

Amalgamation of Medical Colleges.—The subcommittee for arranging a plan for amalgamation between Trinity and Toronto Medical Schools has placed its report in the hands of the general committee. It represents the labors of the subcommittee for the past twelve months. Dr. Irving Cameron was chairman of the sub-committee for Toronto while Dr. Charles Sheard acted in a similar capacity for Trinity. This report will now be sent on to the faculties of the two bodies concerned, when, after being confidentially considered by them, it will become the property of the public.

Ontario's Health.—The Ontario Provincial Board of Health held its quarterly meeting in Toronto last week, under the presidency of Dr. E. H. Vaux, of Hamilton. In his annual address, the chairman referred to the outbreaks of smallpox in several American states, and in other places in Canada. In Ontario, smallpox has broken out during the past year in twenty districts, but the department, through prompt measures of Dr. Bryce, has succeeded in completely stamping it out in each district. Regarding diphtheria, this had shown a falling off during the year, with the single exception of Toronto, where the disease had been very prevalent for some time past, and where the deaths from it alone reached 149 during the past year. This number was remarkable, when it was known that the total death-rate from diphtheria in Ontario was 486. In the month of January there were 21 deaths from it in Toronto. Tuberculosis caused an increase in the death-rate during the year. An important item dealt with by the board was that in reference to consumptives traveling in Pullman cars, and their proper disinfection thereafter. In this connection, the board will seek to co-operate with the railway companies.

FOREIGN.

The French minister of war has ordered that lectures be delivered at army posts on the dangers of drunkenness.

In Budapesth compulsory disinfection of the residence after the death of a tuberculous person is now enforced under penalty.

Dr. G. Holzknecht has been appointed Roentgen-ray expert in Vienna, the courts having created that office on account of the frequency of legal proceedings in which the rays play a part.

Physicians' Tour.—The Paris *Presse Médicale* has organized a "tour of the universities" for a party of forty physicians, to leave May 1. The route includes Lille, Liége, Cologne, Bonn, Heidelberg, Strasburg and Paris.

Serumtherapy.—Three medico-surgical societies of Paris have arranged for a joint meeting March 7, to discuss the question of serums in therapeutics. An address on the subject is to be distributed to all the members ten days before. Similar sessions are to be held from time to time.

Supervision of Medical Journals.—A bureau of medical literature has been organized by the German minister of public instruction as a supplementary measure to his recent decree prohibiting therapeutic or other experiments similar to those for which Neisser was condemned. A complete oversight of all the medical periodicals in the country is the task of the bureau. Our German exchanges have not mentioned this innovation, but it is described in a dispatch to the Paris *Semaine Méd.*, January 30.

Tetanus from Antidiphtheria Serum.—Dispatches to the *Semaine Méd.*, dated January 19, in regard to the cases of tetanus that followed the injection of antidiphtheria serum from the Milan Institute, noted in last week's JOURNAL (p. 391), state that the deaths now number twenty. A portion of the institute building was being demolished at the time the serum was prepared, and contamination may have occurred in this way. The officials of the institute have decided that henceforth the departments in which the various serums are prepared must be entirely separate and remote from each other, and the vials are also fused instead of corked as heretofore. The *British Med. Jour.*, February 2, states that four cases of tetanus following injections of hemostatic gelatin in typhoid fever have also recently occurred in the large hospital at Rome. It was found that the gelatin was prepared in a private pharmacy. An order has since been issued by the board of health that only gelatin prepared in laboratories of recognized scientific standing is to be used.

Vaccination Difficulties in Yucatan.—The surgeon-general of the Marine-Hospital Service has received an interesting report from the United States consul at Progresso, Yucatan, regarding the smallpox in that city and vicinity, and the difficulties encountered in enforcing vaccination. He states that a portion of the population consists of half-breeds known as Mestizoes and full-blooded Maya Indians. Regarding the opposition to vaccination, he writes as follows: "In their old pagan religion the great god 'Kak' was the god of fire and of smallpox, and as God-given the disease was not only to be received without question but to a certain extent courted. Young children were sometimes actually carried to the sick one's bedside to receive the divine fire. This old belief, while not now expressed in words still holds place in their inherent superstition, hence their indifference to the vaccination and the cases of smallpox that, despite all efforts, they will conceal amid the huts. Only when death occurs and the secret can not be hid is the case made public. Fines and remonstrances are in vain with such people. They pay the one and listen to the other with equal impassivity. Compulsory isolation in a public pest-house was tried, but this seemed to turn the passive into open menacing resistance and it was deemed best to modify the decree."

LONDON.

Report of the South African Hospitals Commission.

The report of the commission appointed to investigate the condition of the South African military hospitals, after the publication of Mr. Burdett-Coutts' serious charges, has been issued. The forecast already ventured in THE JOURNAL, that the army medical corps had well performed their duties, but that the red tape of a more or less obsolete war office was at fault, has been verified. It may be remembered that the commission first met in London on July 23 and held six sittings in London, and one at the great hospital and army school of Netley. They then sailed for Cape Town and proceeded up the country, inspecting all the hospitals on the line of route of the troops and taking evidence. They visited Bloemfontein, Kroonstadt, Pretoria and Johannesburg. They then went into Natal and examined the hospitals on their way down to Durban. A difficulty was experienced in getting the evidence of private soldiers, because they were slow in making complaints, more from a feeling of loyalty to their cloth than from being punished by their superiors. But in the hospital they were no doubt deterred by fear of the consequences. Except in certain instances, the complaints against the administration of the army medical corps, against individual hospitals, and against individual officers were found to be somewhat exaggerated, and were based on an insufficient understanding of the peculiar difficulties of the campaign. But there were very serious defects in the medical organization, for which a number of thorough-going reforms are suggested. These reforms are in the main those advocated by Mr. Burdett-Coutts in his letters to the *Times* which produced such a profound sensation.

Inadequacy of the Medical Staff.—The general inadequacy of the medical staff for a war of such unexpected magnitude is insisted on, but this is only part of the inadequacy of the whole military system. The medical corps was insufficient in both staff and equipment, and means were not provided by which its staff could be enlarged or its deficiencies promptly made good. This was not the fault of the medical director general and his staff, because a considerable time before the outbreak they urged upon the military authorities the necessity of an increase of the corps, but for the most part without avail.

Obsolete Ambulance Wagons.—The ambulance wagons were almost universally condemned. They were very heavy, requiring a large number of mules, and were very jolty and uncomfortable. The type used appears not to have been materially changed or improved upon for many years. The commission recommended they should be supplanted by a better type.

Lack of Transport in the General Hospitals.—The fixed general hospitals were generally not furnished with their own transport for the purpose of conveying patients between railway and other stations and the hospital. The transport was ordinarily supplied by requisition on the army service corps. This occasionally led to delay in patients being conveyed to and from the hospital, especially when convoys with sick and wounded arrived unexpectedly at railway stations. The delay was unavoidable because the hospitals had not their own means of transport at hand.

General Efficiency of the Medical Corps, but Need of Reforms.—The report does not endorse the many sweeping charges which have been leveled at the medical corps, and declares that as a whole they deserve great praise for their devotion and capacity and regrets the large number who have died in the discharge of their duty. But it admits that a feeling against the corps exists and that there is need for improvement. Many military officers distrust the skill and professional experience of the army doctors as compared with civil doctors. To a great extent the commission believes that this mistrust is unfounded. That it is not wholly unfounded is explained by the difficulties under which these army doctors work. Even in peace the corps is undermanned and overworked. The majority of the doctors have not sufficient holidays or leave of absence and no adequate opportunities of studying or keeping abreast of recent advances in medicine and surgery. In consequence there is some difficulty in obtaining men of good professional standing to join the corps. Again, the practice of appointing men to important posts by mere seniority is too rigidly followed. The commission recommend that: 1, the staff be permanently enlarged; 2, inducements be offered to ensure a supply of men of good professional attainment; 3, the men who have joined be kept, as a body, acquainted with the general progress of professional subjects.

Deficiency of Staff and Equipment for the War.—At the outbreak of the war there were available staff and equipment only two army corps. An army corps is approximately composed of three infantry divisions of 10,000 men each, and 6000 corps troops—cavalry, artillery, engineers, etc. Even the two army corps which were first employed were staffed and equipped with difficulty. When they were supplied there remained only a reserve equipment sufficient for one general and two stationary hospitals. The explanation for so small a reserve was that improvements were so often made in various articles that it was undesirable to keep a large stock of what might prove useless. For the other corps the deficiency was made up by private hospitals, civil doctors and untrained orderlies. The field-hospitals were ten short of their proper number, which caused a great strain throughout the campaign. At the time of greatest pressure—March, 1900—the total forces amounted to 207,000 men, for whom 800 medical officers—including civil doctors—6000 hospital subordinates, and 800 nurses were employed.

The State of Affairs at Bloemfontein in May.—The condition of the hospitals at Bloemfontein was the *pièce de résistance* of Mr. Coutts' charges. The commission finds that when the army began to advance toward Kroonstadt the field-hospitals had to be cleared in order to accompany the troops and the patients had to be discharged into the general hospitals. As the advance continued the sick and wounded were sent back toward Bloemfontein, with the result that there was great overcrowding of the hospitals. There were deficiencies in bedsteads, mattresses, commodes, bedpans, feeding cups and hospital clothing and an insufficient staff. But this condition was almost impossible to remedy, owing to the congested state of the single line of rail on which the whole army had to rely for food. In certain cases typhoid patients, but not very ill ones, had to attend to themselves.

Skiagraphy in Diseases of the Chest.

At the Medical Society of London, Dr. H. Walsham and Dr. Clifford Beale read an important paper on this subject. In order to obtain a satisfactory shadow, either on the fluorescent screen or the sensitive plate, a powerful coil, capable of yielding a 12 to 14-inch spark, is necessary. The patient should lie prone over the sensitive plate, with the tube two to three feet above the couch, the anticathode in the tube being placed exactly vertical to the part to be examined. Stereoscopic views can be obtained by Mr. Mackenzie Davidson's apparatus. An exposure of two minutes is, as a rule, sufficient. It is always advisable to examine with the screen at the back as well as the front, and useful information can be obtained by diagonal observations. There is no danger of dermatitis when the rays are passed only for a few minutes at a time. Cases of dermatitis have been reported, but the exposures have been excessive—one-half hour to two hours. To interpret morbid shadows, normal ones must be studied. Skiagraphs were thrown upon the screen clearly showing the shadows of the heart, diaphragm and mediastinal tissues, and in addition faint streaks by the left side of the heart shadow, and both sides of the mediastinal shadow. These have been shown by Dr. Walsham's and Dr. Beale's observations to be due to the pericardium and visceral pleura. The shadow of the scapula, the anterior axillary fold and in some cases the shadow of the nipple are easily identified by moving the arms. The very earliest deposit of tubercle does not yield any appreciable shadow. Cases were quoted showing that tuberculous shadows can be detected before there are abnormal physical signs. Cavities are indicated by light areas in dense shadows. Fibroid changes only give a shadow after they attain a definite density and their shadows differ considerably from those of tubercle. Empyema is indicated by exceptional translucency. In early dry pleurisy only a faint shadow can be detected. Serous effusion causes a faint blurring of the rib shadows, but does not obliterate them. Purulent effusion gives very dark shadows. Abscesses and caseating nodules give dark shadows. By far the most important use of skiagraphy in chest disease is for the detection of aneurysms and morbid growths. It may give evidence far more precise and definite than that obtained by ordinary methods.

Uremic Convulsions Successfully Treated by Bleeding and Saline Transfusion.

At the Liverpool Medical Institution, Dr. R. T. Glynn recently related the case of a man, aged 31, who entered the hospital with acute nephritis, apparently of ten days' duration, and probably the result of alcoholism and a chill. The urine was scanty, of high specific gravity and very albuminous. The pulse was tense and the heart enlarged. Notwithstanding the administration of purgatives and diaphoretics, including the hypodermic injection of pilocarpin and the restriction of food to diluted milk, uremic symptoms developed four days after admission. One fit followed another, with coma, stertor, cyanosis and contracted pupils. The condition having lasted several hours, two pints of blood were removed and one of saline solution was injected into the connective tissue of the axilla and shortly afterward one-half pint into the rectum. The convulsions ceased and consciousness returned. He perspired freely for the first time and on the next day passed 46 ounces of urine, 20 ounces having been the maximum in the twenty-four hours previous. In the following ten days he passed on an average 70 ounces of urine in twenty-four hours. The albumin disappeared, the arterial tension decreased, the apex of the heart returned to its normal site, and he left the hospital in about a month, apparently quite well.

Correspondence.

Water in Typhoid Fever.

Saratoga Springs, N. Y., Jan. 29, 1901.

To the Editor:—In The Journal of January 24 there was an article by Dr. Anders, of Philadelphia, on the use of large quantities of water in typhoid fever, and I was particularly pleased that so eminent an individual as Dr. Anders endorsed the procedure in this manner and thought it worthy of attention at a meeting of the American Medical Association. In 1898 I read an article on the use of water in typhoid fever before our local society, emphasizing the great quantities required in some cases, the difficulties in teaching nurses to give the required amount, the very great influence it exercised over all the symptoms, that the patient's condition was not so critical with a very high temperature if plenty of water was given, that if a sufficient quantity were given tub-baths were not imperative, which in private practice will be appreciated by most of us, and lastly, that the guide to the quantity of water required in each individual case was the *tongue*—this member must be moist at all times regardless of the quantity consumed.

I sent this manuscript to a weekly medical journal for publication, and it was returned to me with the information—though I can not give the exact wording—that the article was too visionary. It was, however, promptly published by the *Albany Medical Annals*, and I am glad to have the commendation expressed by Dr. Anders' article for the thoughts expressed at that time.

I have been using quantities of water as suggested in my practice since 1895, with the greatest comfort to myself and benefit to my patient. In 1898 I had only treated nineteen consecutive patients without a death, now the number is something over fifty. Many of these have been most desperate cases, and we are sure that the use of water has been a factor in their recovery. Surely no one who has been in the habit of treating typhoid fever without quantities of water internally can realize what it means to see the patient going through such an illness with the high temperature, nervous manifestations, sordes, dry tongue, and, practically, all the complications mitigated or absent. I find that patients require much larger quantities of water than mentioned by Dr. Anders. He speaks of 5 or 6 quarts as being often required in twenty-four hours, but I find that it is often necessary to use very much more, and I frequently note that the patient has taken from 8 to 16 quarts in twenty-four hours. To one who has not used this quantity the administration would seem almost impossible. It requires determination on the part of the physician, with a consciousness that it is the proper treatment, to insist that the nurse does as directed, and this is the particular thing which seems very difficult for them to understand, appreciate or execute.

The guide to the amount of water required is a very important one, and is not mentioned by Dr. Anders, or others, so far as I know, at all; that is, that the tongue must be moist at all times. This will necessitate the patient's being disturbed at least every half hour, perhaps oftener, to be given from 4 to 8 ounces of water, but unless this is done no conclusions can be deduced concerning its value in these cases. Yours truly,

511 Broadway.

D. C. Moriarta, M.D.

The New Method of Inducing Sleep Without Drugs: One-Hundred-Dollar Prize.

NORTHAMPTON, MASS., Jan. 30, 1901.

To the Editor:—The one grand step in scientific medicine during the centuries has been that just accomplished at the close of the nineteenth. Tuberculosis is now to be cured by sunshine, open-air exercise and plain food. Drugs, predigested foods and the poisonous inhalations of the closed wards are recognized as causes rather than cures of tuberculosis.

A revolution of no less importance is in process to liberate the non-sleeping, hypnotic, drug-taking brain-workers now on duty in all the great centers of this country. Drug unconsciousness is causative, not curative, of insomnia. By well-trained will power we may command quiet in the workshop of the brain, as we may in the mill. It is all a matter of turning on and off the belts.

"The New Method of Inducing Sleep Without Drugs" consists in bringing under control two functions of organic life at the retiring hour. The organs of respiration and circulation respond at once to our bidding, and automatic brain activity is rendered impossible. To "stop thinking" is to begin sleeping. Normal sleep is reparative. Drug unconsciousness is destructive.

Believing the medical profession has power to turn the attention of suffering humanity from the chimerical and damaging drug agents they now resort to and depend on, and that it is our duty to shed light rather than darkness, I offer a prize of $100 for an essay describing any method that will equal or surpass the one above referred to.

Judges of the merits of essays offered will be representative men of scientific medicine. The time allotted for preparing the essay is the first half of the year 1901, the essay not to exceed four thousand words. Only type-written or printed matter will be examined. All names will be withheld until the award is given. J. B. LEARNED, M.D.

Married.

JAMES S. DAWSON, M.D., Perry, N.Y., to Miss Verdi Dennison, of Canisteo, January 30.

PETER E. HYRUP-PEDERSON, M.D., to Miss Marie Louise Alsop, both of Laramie, Wyo., January 24.

MOLLIE V. LEWIS, M.D., Madison, Ind., to Mr. John Sarran, of Indianapolis, at Vevay, Ind., January 30.

Deaths and Obituaries.

Abraham Bettman, M.D., an old resident of Cincinnati, Ohio, who settled there in 1846, and with the exception of three years spent in Chicago, lived afterward in that city, died after an illness of a week, from kidney disease, at his home in Cincinnati, January 14, at the age of 95. He studied medicine in the universities of Wurtzburg, Erlangen, Heidelberg and Munich, and graduated from the latter in 1842. He then took a post-graduate course in Vienna under Professor Skoda. He retired from active practice in 1880. In 1892 the University of Munich, in honor of the fiftieth anniversary of his graduation, sent him an honorary diploma.

William W. Lane, M.D., New York University, 1855, died at Wilmington, N. C., from cirrhosis of the liver, February 4, aged 69. After his graduation, Dr. Lane studied two years in Paris, and then settled in Vicksburg, Miss., and on the outbreak of the Civil War, served on the Confederate side. 1870 he moved to Wilmington and was put in charge of the U. S. Marine-Hospital in that city. In 1881 he was placed in charge of the City Hospital, a position which he filled until his death.

Benjamin Franklin, M.D., New York University, 1868, died at his home in Newark, N. J., from la grippe on February 6. During the Civil War he was a prisoner for seven months at Andersonville and he also served with the Cuban patriot army in the ten-years war. He was a member of THE AMERICAN MEDICAL ASSOCIATION.

Emery A. Merrifield, M.D., Albany Medical College, Albany, N. Y., 1853, of Macon, Mo., died at the Baptist Hospital, St. Louis, December 7, aged 74. He practiced in Herkimer county, New York, until 1860, when he went into the service as surgeon of the 58th Illinois Volunteers and served throughout the war.

Michael Royston Pigott, M.D., University of Virginia, Passed-Asst. Surgeon, U. S. Navy, died suddenly at the Naval Academy, Annapolis, Md., January 31, aged 35. He was a native of Massachusetts and instructor in physiology and hygiene at the Naval Academy.

Newton J. Wedgewood, M.D., Medical School of Maine, Brunswick, 1870, of Lewiston, Me., and a member of the Androscoggin, Maine Medical, and THE AMERICAN MEDICAL ASSOCIATIONS, died at his home in Lewiston, February 5, from Bright's disease, aged 54.

Walter Myers, M.D.—The Liverpool School of Tropical Medicine announces, with deep regret, the death, from yellow fever, of Dr. Walter Myers, one of the members of the yellow fever expedition of that school, who lost his life in the cause of humanity and science.

Henry F. Baxter, M.D., University of Pennsylvania, 1864, a member of the County Medical Society and of THE AMERICAN MEDICAL ASSOCIATION, died at his home in Philadelphia, February 1, after a prolonged illness, at the age of 57 years.

John M. Hundley, M.D., Jefferson Medical College, Philadelphia, 1849, at one time a prominent physician of Essex County, Va., died after an illness of three years from paralysis, at his home in Montague, January 30, aged 75.

Lincoln Johnson, M.D., Columbian University, Washington, D.C., 1894, died January 2 from yellow fever, at Bocas del Toro, Colombia, South America, where he had gone to engage in practice. He was 32 years old.

Clayton A. Cowgill, M.D., Pennsylvania Medical College, Philadelphia, 1846, who retired six years ago after nearly half a century of practice in Dover, Del., died at his residence in Philadelphia, February 2, aged 74.

Daniel W. Hazelton, M.D., Vermont Medical College, Woodstock, 1848, of Springfield, Vt., the oldest practicing physician in the locality, died in Bellows Falls, Vt., January 31, from pneumonia, aged 76.

David N. De Tar, M.D., University of Michigan, Ann Arbor, 1880, died January 31, at his home in Boone, Iowa, from cerebral hemorrhage, following an attack of cholelithiasis. He was 48 years of age.

William H. Scott, M.D., Meharry Medical College, Nashville, Tenn., 1886, a colored physician of Houston, Texas, died at his home in that city, February 1, after a prolonged illness.

Ira Doan, M.D., Medical College of Indiana, Indianapolis, 1880, of North Bend, Neb., a member of THE AMERICAN MEDICAL ASSOCIATION, died suddenly at Fremont, Neb., February 6.

Charles Osborn, M.D., Rush Medical College, Chicago, 1890, of Lyons, Iowa, coroner of Clinton County, died February 2 from apoplexy, at Mercy Hospital, Dubuque, Iowa, aged 35.

Jacob H. Putnam, M.D., Long Island College Hospital, Brooklyn, N. Y., 1867, of Rutland, Vt., died from pneumonia at the Buffalo General Hospital, January 28, aged 61.

Rosier Middleton, M.D., Columbian University, Washington, D. C., 1889, died from consumption after a long illness at the Columbian University Hospital, January 31.

Lewis Buffett, M.D., who went to Maryland from Cleveland, Ohio, in 1891, died at his home near Easton, Md., January 27, from carcinoma of the stomach.

Samuel H. Cade, M.D., Medical College of Alabama, Mobile, 1874, died at Negreet, La., where he had resided for the past twenty-five years, February 7.

Augustine Shurtleff, M.D., Harvard University Medical School, Boston, 1849, died at his home in Brookline, Mass., January 27, aged 74.

John E. Garner, M.D., College of Physicians and Surgeons, Baltimore, Md., 1876, died suddenly at his home near Union, S. C., February 3.

Wiley W. Bloodworth, M.D., Jefferson Medical College, Philadelphia, 1850, died at his home in Pratt City, Ala., January 28.

J. B. Darling, M.D., Starling Medical College, Columbus, Ohio, 1857, died at Austin, Ill., February 2.

James Harty Kennedy, M.D., McGill University, Montreal, died recently at Michipicoten, Ontario.

Henry C. Hill, M.D., University of Michigan, 1859, died at Lockport, N. Y., February 8, aged 60.

Samuel C. Busey, M.D., of Washington, D. C., died February 12. His obituary will appear next week.

Book Notices.

MALARIA ACCORDING TO THE NEW RESEARCHES. By Prof. Angelo Celli, Director of the Institute of Hygiene, University of Rome. Translated from the Second Italian Edition, by John Joseph Eyre, M.R.C.P., L.R.C.S. Ire., D.P.H. Cambridge. With an Introduction by Dr. Patrick Manson, Medical Adviser to the Colonial Office. With Maps and Illustrations. Cloth. Pp. 275. Price $3.00. London, New York, and Bombay: Longmans, Green & Co. 1900.

"We owe to the Italians not only the name but also much of our knowledge of malaria." Thus Dr. Patrick Manson begins his *Introduction* to the work, and one of the most eminent of these Italian students of the epidemiology of paludism is Professor Celli. Dr. Manson further says: "I saw the peasants whose sordid lives he describes so graphically, and I saw in operation the economic system which, together with malaria, has reduced these wretched people to what is practically a position of slavery."

In the chapter on the history of malaria the author dwells upon the drainage system, the cloacæ and aqueducts of the early Romans, and shows how they had maintained a sanitary city, although surrounded by a deadly malarial zone. Many passages from the ancient Latin writers—Horace, Pliny, etc.—are quoted, and show the dread with which the surrounding Campagna was regarded at that time. Later, foreign invasions and civil strife destroyed the work already done and nullified the efforts of the popes to drain the Agro Romano, and thus reduced it to an uninhabited waste.

The scientific consideration of malaria is fully taken up by the author, and numerous illustrations render the text clear. The book affords instructive and interesting reading.

MANUAL OF THE DISEASES OF THE EYE. For Students and General Practitioners. With 243 Original Illustrations including 12 Colored Figures. By Charles H. May, M.D., Chief of Clinic and Instructor in Ophthalmology, College of Physicians and Surgeons, New York. Cloth. Pp. 406. Price, $2.00. New York: William Wood & Co. 1900.

This concise and useful little manual is intended for the student and general practitioner. The text is elucidated by numerous illustrations both of ocular diseases and the instruments in general use by the ophthalmologist. There are several colored plates of the normal and pathologic fundus. Errors of refraction are fully explained and the different methods of their recognition and correction made clear. We confidently recommend the work.

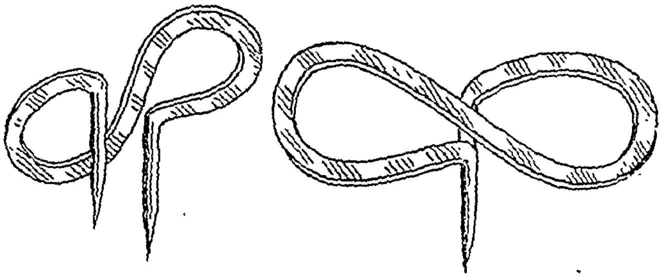
New Instruments.

New Bandage Pin.

GEORGE D. McLEAN.

NASHVILLE, TENN.

I present illustrations of a bandage-pin recently devised by me. The pin is made as follows: A figure-of-eight piece of wire having the two ends turned at right angles to the plane of base and the ends sharpened. The base is flattened and the two prongs extend one-half to five-eighths of an inch up from the base, perpendicular to it and parallel to each other. These two are about one-fourth of an inch apart. In applying a bandage, say a recurrent of the scalp, after making one turn around the head to fix the bandage place one pin on the inion and one just above the sinciput; this will enable the surgeon, by pressing the bandage down over the extending prongs, and returning over them, to apply this bandage alone and with a single-headed roller bandage. After enough has been put on, separate the prongs and turn down against the head, making, if desired, one turn around to hold them down and protect the points. This pin will work in any spica, figure of eight, or recurrent, as of a stump, absolutely preventing slipping at the point of application. The device is simple, and it is strange that it is not already in use; but I have been unable to find any one who has heard of one used by surgeons. The pin has been commended by many of the physicians of Nashville, and will, I think, meet the approval of all who have to use bandages.

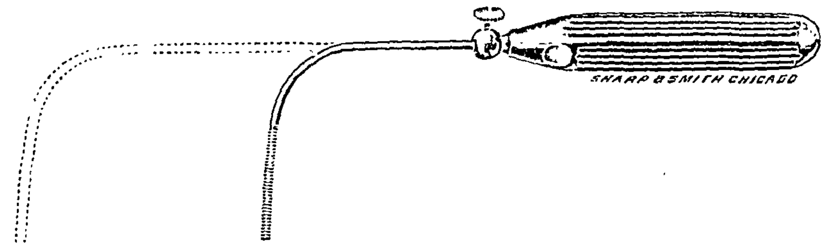


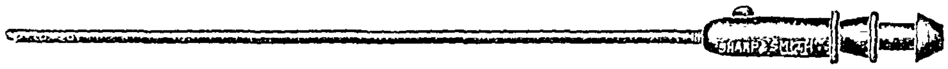
A Nasal Irrigator, Intratracheal Spray and Laryngeal Applicator.

OTTO T. FREER, M.D.

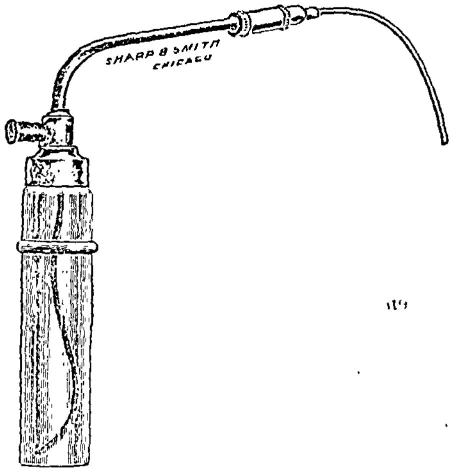
CHICAGO.

The instruments here described have grown out of the needs of practice and have all seen lengthy service in my hands. To avoid the danger of fluid penetrating the middle ear, incident to the use of the nasal douche or syringe, I have devised the little irrigating tube shown in the cut. It is made of hard rubber, hence has some elasticity, and is perforated near its end by three minute holes, 1/64 inch in diameter. The tube is connected to a fountain syringe by the usual coupling for Eustachian catheters, and emits three tiny but forcible jets that are not large enough to flood the nose or nasopharynx, but undermine and wash adherent pus or crusts from these regions. I give the tube to the patient to use at home, and during many years of its employment have never had any complaint of ear symptoms, while the patients, even in marked cases of ozena, keep the nose and nasopharynx clean. In aggravated cases I aid the use of the tube by means of oily applications to soften the crusts. The advantage of the instrument over the postnasal syringe is that during the use of the latter the patient is apt to raise the soft palate and so diminish or entirely obliterate the postnasal space, thus preventing irrigating fluids from reaching the parts to be cleansed. By rotation of the tube the streams can be made to reach any part of the nasal fossæ from the roof to the floor. More than three holes were found to unduly diminish the force of the streams and to emit too great an amount of fluid. Metal tubes are too stiff and cause pain.





The second instrument shown is a spray tube that I have designed for intratracheal applications in chronic tracheitis, especially the dry form with crusts. The appliance screws on to the regular Davidson atomizer with nasal tip, and its end can be easily passed between the vocal cords, by aid of the mirror. In sensitive larynges local anesthesia of slight degree is needed. The instrument emits a coarse spray within the trachea. It has been suggested that a laryngeal syringe passed into the trachea would do equal service. The advantages of a spray are that minute amounts of concentrated solutions can be evenly applied to a large surface while the irritation caused by the necessarily large amounts of fluids of the same strength used in a syringe would be intolerable. Even in large quantity the fluid so injected would not apply itself as uniformly as if sprayed. For certain cases the tubes need to be of extra length to reach far enough down to enter the trachea.



The third instrument is a strong laryngeal applicator with a heavy handle through which the shank of the applicator passes so that it can be adjusted in length. The end of the instrument is fitted with a screw thread. It is quite impossible for cotton swabs wound on this to become detached. I devised the instrument as I found that the ordinary light laryngeal applicators with small handles were apt to rotate in the hand if the extremity touched any part of the pharynx or the epiglottis. The weight and firmness of the instrument fits it especially for vigorous applications of lactic acid to the tubercular larynx, or for massage of thickened laryngeal mucous membrane.

288 E. Huron Street.

Miscellany.

The Duration of Life.—The question is often raised whether the great advances in the arts and sciences have, after all, contributed to the prolongation of life. Such evidence as is accessible would seem to point in the affirmative. Thus, in England and Wales, during the period of 1841 to 1850, the death-rate among males of all ages was 23.1 and among females 21.6 per 1000, while during the years from 1886 to 1889, the death-rate was 20 per 1000 for males and 17.8 for females. It therefore appears that within fifty years there has been a clear gain of more than three lives in every thousand. The birth-rate in England has, however, declined during the corresponding period, having been, in 1842, 32.6 per million of population, while from 1886 to 1890 it was 31.4.

The Postural Treatment of Bronchial Affections.—The physician often has reason to doubt the efficacy of his treatment of bronchial affections, particularly when these have become chronic, and some suggestions made by Jacobson (*Berliner Klin. Woch.*, 1900, No. 41, p. 904) in a recent communication, may prove of practical utility in this connection. It is pointed out that the first indication in the treatment of all bronchitic disorders consists in removal of the morbid bronchial secretion. This is especially attended with difficulty in the presence of chronic processes, when the sensitiveness of the mucous membrane to irritation is diminished. Under such circumstances it is customary to replace the physiologic irritation resulting from the contact of the secretion with normal mucous membrane by chemical irritants—so-called expectorants. The resulting effect is general and not local, and stimulates increased production of secretion. Bronchiectatic processes, however, do not yield to such treatment; nor is the outlook for surgical intervention hopeful, inasmuch as the lesions are often multiple and bilateral. Quincke has proposed the removal of the accumulated secretion by gravitation, placing the patient in a prone position, with the head below the level of the body. In its gradual escape the secretion reaches healthy mucous membrane, which it irritates. It thus excites cough and expulsion, while at the same time air enters previously airless portions of lungs, respiration assumes more the costal type and the pressure of the abdominal organs upward on the diaphragm facilitates expiration. Besides, the expectoration can be regulated, so that it shall take place at stated intervals and not be continued throughout the day. Further, extension of the morbid process and the development by aspiration of bronchopneumonia and putrid decomposition are by this means prevented. The procedure is also applicable in the presence of fetid bronchitis. It is contraindicated when acute conditions or a single large abscess exists. Cylindrical bronchiectases are more favorably influenced than saccular. Pulmonary abscess and empyema are not well suited to this means of treatment. The patients are placed in the desired position for an hour morning and evening.

Therapeutics.

Renal Colic.

The following outline of treatment is given by Gould: For the acute attack hypodermic injections of morphin, gr. 1/4 combined with atropin, gr. 1/120 and repeated in two hours if necessary. Hot flannel cloths, stupes or poultices should be applied over the affected area. In recurrent attacks attention to elimination by the bowels, skin and kidneys should receive the proper notice. Rochelle salts ʒiv, Epsom salts ʒiv, or Carlsbad ʒi-ii for the bowels, and one of the following prescriptions to promote diuresis and render the urine alkaline:

R.	Lithii citratis	ʒi	4	
	Ext. hydrangeæ flu.	ʒiv	16	
	Infusi tritici q. s. ad	℥vi	192	

M. Sig.: One tablespoonful every four hours in water.

Hydrangea is an unofficial preparation, but is classified by Potter as of special importance in treatment of renal calculus by relieving the pain during the passage of renal concretions through the ureters or in promoting the removal of gravel from the bladder: or

R.	Lithii citratis	ʒi	4	
	Pot. citratis	ʒiss	6	
	Ext. zeæ fluidi	℥i	32	
	Infusi uvæ ursi q. s. ad	℥vi	192	

M. Sig.: One tablespoonful every four hours.

As a Laxative for Children.

R.	Mannæ	℥ss	16	
	Magnesiæ—calcined			
	Sulphuris loti, āā	℥iss	48	
	Mellis despumati q. s. ad	℥iv	128	

M. Sig.: A tablespoonful to be taken in a cup of hot milk. The dose can be increased if necessary.

Follicular Tonsillitis.

℞.	Creosòti	m. x		65
	Tinct. myrrhæ			
	Glycerini, āā	℥i	32	
	Aquæ q. s. ad	℥iv	128	

M. Sig.: Use as a gargle or spray four or five times daily.

ACUTE FOLLICULAR TONSILLITIS.

Dr. D. R. Brower has always derived splendid results from the use of the following combination, having first administered a mercurial or saline purgative:

R.	Potassii chloratis	ʒss	2	
	Acidi hydrochlor. dil	ʒii	8	
	Tinct. ferri chloridi	ʒiii	12	
	Glycerini	℥i	32	
	Syr. tolutani q. s. ad	℥iii	96	

M. Sig.: One teaspoonful in water every two hours.

ABORTMENT OF FOLLICULAR TONSILLITIS.

The *Medical Council* states that follicular tonsillitis, if seen early, may be checked by swabbing the throat with the following:

℞.	Potassii chloratis	gr. xxx	2	
	Tinct. ferri chloridi			
	Glycerini, āā	ʒiiss	10	
	Aq. destil. q. s. ad	℥i	32	

M. Sig.: Swab the throat every two hours with this solution, alternating with a solution of peroxid of hydrogen, to be used in the same way.

After swabbing, a tablet of hydrargyri chloridum mite and sodium bicarbonate is to be dissolved in the mouth after each swabbing.

For the headache, soreness and other disturbances the following is recommended internally:

R.	Acetanilidi	gr. xxxv	2	33
	Camphoræ monobromatæ	gr. viii		5
	Sodii salicylatis	gr. xv	1	
	Extracti hyoscyami	gr. ii		12

M. Ft. capsulæ No. xv. Sig.: One capsule every hour until relieved or until five have been taken.

For children the same treatment is recommended, except the mercurial tablets are stopped as soon as the bowels have moved freely and the last-mentioned capsules are proportionately reduced to the age of the child.

To Remove Tattoo Marks.

The "Clyclopedia of Med. Surgery" describes the method of Variot as follows: The skin is first covered with a concentrated solution of tannin, and retattooed with this in the parts to be cleared. Then an ordinary nitrate of silver crayon is rubbed over these parts, which become black by formation of tannate of silver in the superficial layer of the derma. Tannin powder is sprinkled on the surface several times a day for some days, to dry it. A dark crust forms, which loses color in three or four days, and in two weeks comes away, leaving a reddish scar, free of tattoo marks, which in a few months is but slightly noticeable. It is well to do the work in patches about the size of a dollar at a time. The person can thus go on with his usual occupation.

PAPAIN IN REMOVAL OF TATTOO MARKS.

Ohmann-Dumesnil recommends the following for removal of tattoo marks:

℞.	Papainæ	ʒiss	6	
	Acidi hydrochlorici dil	m. xv	1	
	Aquæ destil	℥i	32	
	Glycerini	℥iii	96	

M. Rub the papain in a mortar while adding the mixture of water and acid, allow the paste to stand an hour, add the glycerin and in three hours filter. Sig.: For local application three or four times daily.

Eczema Capitis.

In this form of eczema, Joseph Max, in *Med. News*, prescribes the following to destroy the pediculi when present:

R.	Hydrarg. chloridi corros.	gr. i		06
	Vinegar	℥i	32	

M. Sig.: Apply twice daily.

In a few days apply the following ointment:

R.	Hydrarg, oxidi rubri	gr. iv		25
	Sulphuris sublim.	gr. xx	1	33
	Ol. bergamotæ	gr. viii		5
	Vaselini q. s. ad	℥i	32	

M. Sig.: Apply locally once or twice daily.

Treatment of Diabetes.

The *Ther. Gazette* contains the following combination containing boric acid, which it is claimed has been of curative benefit in treatment of diabetes. The cases in which it was used were young persons:

℞.	Acidi borici	gr. xx	1	33
	Glycerini	ʒi	4	
	Liq. arsenici hydrochlor	m. v		33
	Liq. strych. hydrochlor	m. x		66
	Aquæ destil. q. s. ad	℥i	32	

M. Sig.: To be taken at one dose and repeated three times a day.

The arsenic and strychnin preparations are of one per cent. strength as contained in the British Pharm., and consequently the above dose of strychnin is on the border line of danger and probably should never be prescribed in such size doses. It should be prescribed in doses of three to five minims.

For the Neuralgic Pains in Tuberculosis.

The following liniment is prescribed by the *Monthly Encyc. of Pract. Medicine*:

℞.	Menthol.			
	Spts. chloroformi, āā	ʒiii	12	
	Chloralis hydratis	℥ss	16	
	Spts. camphoræ	ʒiii	12	
	Alcoholis q. s. ad	℥iv	128	

M. Sig.: To be applied locally and thoroughly rubbed in.

For the night sweats, the afternoon bath and friction, or the administration of atropin or argaracin, are usually sufficient: in persistent cases potassium tellurate in daily doses of one-half grain to be taken at night. For the irritating cough, unaccompanied by expectoration, heroin in doses of one-twelfth to one-sixth grain is valuable.

Headache from Eyestrain.

Dr. Casey A. Wood, in *Med. News*, states that this form of headache is most frequently encountered in strain of the ciliary muscles. He recommends very cold or very hot compresses, gently pressed over the closed eyes and forehead and advises them to be repeatedly changed for ten minutes. and repeated every hour while the headache lasts. For local application he recommends:

℞.	Spts. camphoræ	℥ss	16
	Spts. lavendulæ		
	Alcoholis, āā	℥iss	48

M. Sig.: Apply locally; or:

R.	Camphoræ		
	Tinct. aconiti		
	Ol. menthæ pip. āā	ʒi	4
	Chloroformi	℥ss	16
	Alcoholis q. s. ad	℥iii	96

M. Sig.: Shake well and apply every two or three hours.

He further states that relief may be obtained by applying the galvanic current to the eyes, using a current strength of three to five milliamperes, and placing the positive pole to the nucha, and the negative to the closed lids, for five or six minutes.

Ointment for Acute Eczema.

Wendle, in *Jour de Méd. de Paris*, recommends the following:

℞.	Acidi camphorici	ʒi	4
	Bismuthi subnitratis		
	Zinci carbonatis		
	Pulveris amyli		
	Vaselini		
	Lanolini (anhydrous) āā	ʒii	8

M. Sig.: Apply locally to the affected parts.

Ergot in Diseased Conditions of the Prostate.

E. R. Corson, in *Merck's Archives* recommends the following, which he finds useful, especially in congestion and inflammation caused by gonorrhea:

℞.	Tinct. aconiti	ʒi	4
	Tinct. gelsemii		
	Antipyrini, āā	ʒii	8
	Ergotol	℥i	32
	Aquæ destil. q. s. ad	℥iv	128

M. Sig.: One dessertspoonful in a wineglass of water every two or three hours.

He states that the action of ergot is aided by a combination with a potash salt, generally the bromid.

Ointment for Varicose Ulcers.

℞.	Acidi carbol	ʒss	2
	Acidi borici	ʒiiss	10
	Camphoræ	ʒii	8
	Ichthyol	ʒv	20
	Ol. amygdalæ dulc.	ʒiiss	10
	Ung. zinci oxidi	℥iiiss	112

M. Sig.: Apply externally night and morning.

Treatment of Epistaxis from Any Cause.

Dr. P. Chevallier, as quoted in *St. Paul Med. Jour.*, recommends injections of gelatinized serum prepared as follows:

℞.	Sodii chloridi	ʒii	8
	Aq. destil	Oii	1000

M. To this solution add gelatin in proportion of 10 parts to the 100 and sterilize. This becomes solid when cooled, but can be warmed in a waterbath when needed. As an astringent powder the following is recommended:

℞.	Acidi borici		
	Pulv. sacchari, āā	lxxv	5
	Antipyrini		
	Acidi tannici, āā	gr. xv	1

M. Sig.: To be blown upon the bleeding surfaces.

If it is not then checked, packing the nostril will have to be resorted to.

Treatment of Furuncles.

Philipson, as published in the "New Year-Book of Med.," recommends salicylic acid in 50 per cent. strength in treatment of well-formed furuncles. The following paste is applicable for such conditions:

℞.	Acidi salicylici	℥i	32
	Pulveris amyli	ʒi	4
	Lanolini	℥i	32

M. Sig.: Apply locally and change three or four times a day in order to hasten the necrotic process.

When the core has been eliminated, he advises treatment which will favor granulations. Minute furuncles may be checked by applying the following:

R.	Tincturæ benzoini	ʒi	4
	Alcoholis—puri—q. s. ad	℥iii	96

M. Sig.: Apply locally three times a day.

In generalized furunculosis the parts should receive a warm bath daily and then be rubbed with the following:

R.	Acidi salicylici	gr. xxv	1|66
	Vaselini q. s. ad	℥ii	64

M. Sig.: To be well rubbed in over the affected area.

Societies.

COMING MEETINGS.

Southwestern Iowa Medical Association, Creston, Ia., Feb. 21, 1901.

Tri-State Medical Association of the Carolinas and Virginia, Richmond, Va., Feb. 26, 1901.

Medical Society of the Missouri Valley, Omaha, Neb., March 21, 1901.

West Texas Medical Association.—At the meeting of this Association, held in San Antonio, January 3, resolutions passed opposing the unrestricted sale of morphin, cocain and other poisonous drugs and favoring legislation in that direction.

Calcasieu Parish (La.) Medical Society.—The physicians of St. Charles and of Calcasieu Parish organized this Society. February 4, and elected Dr. Erastus J. Lyons, St. Charles, president; Dr. V. A. Miller, Lake Arthur, vice-president, and Dr. C. Pearl Munday, West Lake, secretary and treasurer.

Cripple Creek District (Colo.) Medical Society.—At the semi-annual meeting of this Society, held at Cripple Creek, January 30, the following officers were elected: Dr. William J. Chambers, president; Dr. Harry S. Torrance, and Francis J. Crane and Marion A. Latimer, Victor, vice-presidents; Dr. Benjamin B. Frankle, secretary, and Dr. J. Ernest Meiere, treasurer.

Quarter-Century Medical Club.—This Society, whose membership is made up of those who have practiced medicine for five-and-twenty years or more in Detroit, Michigan, held its annual meeting and banquet, January 30. Dr. Eugene Smith was elected president; Dr. H. A. Cleland, vice-president; Dr. John G. Johnson, treasurer, and Dr. Robert A. Jamieson, secretary.

Northeastern District Medical Society of Michigan.—This Society held its forty-ninth annual meeting in Flint, January 31, and elected Dr. Philip A. Knight, Utica, president; Dr. George S. Ney, Port Huron, vice-president; and Dr. A. Henri Cole, Port Huron, secretary and treasurer. This is said to be the oldest medical society in Michigan and takes in St. Clair. Macomb, Lapeer, Genesee and Sanilac counties.

Shawnee County (Kan.) Medical Society.—The Topeka Academy of Medicine and Surgery has been disbanded and the Shawnee County Medical Society was organized in its place, at Topeka, February 4, in accordance with the plan of the committee of The American Medical Association. There were 24 charter members present, and the following officers were elected: Dr. Lewis Y. Grubbs, president; Dr. Herbert L. Alkire, vice-president; Dr. Josiah P. Lewis, treasurer, and Dr. William E. McVey, secretary.

Salt Lake Medical Society.—The last meeting of this Society was devoted to the steps to be taken to prevent the passage of the anticompulsory vaccination bill now pending in the legislature. A committee was appointed to guard the prerogatives of the health board against any invasion. This committee will go before the legislative committee that has the bill in hand and lay before it the reasons for their opposition to the bill.

Eastern Hampden (Mass.) Medical Association.—The twenty-first annual meeting of this Association was held at Springfield, January 31, when these officers were elected for the ensuing year: Dr. Walter R. Weiser, Springfield, president; Dr. George W. Rawson, Amherst, vice-president; Dr. Vincent J. Irwin, Springfield, secretary and treasurer; Dr. George L. Woods, Springfield, censor. Dr. J. M. Fay, Northampton, read a paper on "Etiology." Dr. Angelo O. Squier, Springfield, was toastmaster.

PAN-AMERICAN MEDICAL CONGRESS.

Held in Havana, Cuba, February 4.

The Third Pan-American Medical Congress can not be said to have been a success in every particular. The scientific program, as printed, made one anticipate a large amount of scientific work, an anticipation that was not realized. A large number of those whose names appeared on the program were not present, and while a few of these sent their papers, many did not. This was especially noticeable as regards those from the United States.

The number present was far from satisfactory, and as a result the sections were very poorly attended. The following was the registration according to countries: Mexico, 7; Guatemala, 2; Nicaragua, 1; Argentine Republic, 3; Porto Rico, 3, Peru, 2; Venezuela, 2; Brazil, 1; Cuba, 26; United States 77; Canada, 2; Honduras, 1. The Congress being divided into twenty-two sections, many of these did not materialize as far as was observed. The sections on gynecology and abdominal surgery, general medicine and ophthalmology, seemingly, were the most interesting and attractive, and the number in attendance on the first two mentioned was often as great as fifteen or twenty, but a half dozen to a dozen was a common average in most of the sections.

The general sessions, from the point of view of those who understand Spanish, were more or less successful, but to those who did not speak the language of the Cubans it could hardly be said that they were entirely satisfactory. The first general session, which was dignified by the appellation" Solemn Inaugural Session," was held on Monday evening at the "Gran Teatro de Tacon," the largest theater in Havana. The house was filled with the elite of the city, in all the glory of full dress and Spanish beauty. The meeting was presided over by Dr. Wood, the Governor-General, whose few choice words of welcome were the only ones spoken in the English language. The secretary-general made his report, and the president of the Congress, Dr. Fernandez, delivered an address of welcome occupying about twenty minutes. Then followed the principal address of the evening, an hour long, by Dr. Eusebio Hernandez, the subject being obstetrics, certainly not a very appropriate one for a mixed audience, that is, from the view point of an American. Thus the entire evening, with the exception of the five minutes by General Wood, was occupied by those speaking Spanish.

Etiology of Yellow Fever.

The most important scientific development of the Congress was the report made by Dr. Reed of his experiments on yellow fever. Major Reed's request to General Leonard Wood for $5000 for the purpose of hiring men to submit to these experiments and to the bite of the mosquito was granted on condition that the men should be apprised of their danger and sign papers to that effect: "that it should be of their own free will in every particular, and that, in case of Spaniards, the Spanish consul's permission should be obtained." They were paid $250 each. Major Reed's paper is printed in full in this issue of The Journal, p. 431, also an editorial comment, p. 446.

DISCUSSION.

Dr. Louis Perna, Cienfuegos, Cuba, in opening the discussion, said that it is sophism to believe that *post hoc ergo propter hoc*, that is to say, that as Carmona, Freire, Sanarelli and others have fallen to this error, we must not be too precipitate in accepting the result of statistics. The studies made of mosquitoes are very old. A French physician, who died about 1850, expressed the opinion that malaria, yellow fever and cholera w [illegible] mosquitoes. Dr. Perna also criticised the [illegible] by the Commission in making experiments on human beings and is entirely opposed to such experiments.

Dr. San Martin eloquently defended, and with strong arguments, the high scientific standard of the experiments as carried out by this Commission, and also brought out the point that it was not statistics but facts that this Commission presented.

Dr. H. B. Horlbeck, Charleston, S.C., expressed his opinion that the problem of 200 years was about to be solved, that the old quarantine regulations should be greatly modified. He also described the existence of a pine belt within a short distance of Charleston, S. C., in which yellow fever never developed as an epidemic, although the afflicted therewith would go there during the existence of the epidemic in Charleston, would die from the disease and yet it would not spread. Mosquitoes are not known in that region, and probably this is the true explanation of the above fact. He concluded by emphasizing the inestimable value of these experiments if they prove to be true.

Dr. Emilio Martinez, Havana, laid emphasis on Dr. San Martin's views. He took up the moral question and claimed that without these no truth could have been found.

Dr. Manuel Gutierrez, Mexico, who up to within a short time had been adverse to the theory of the transmission of this disease by mosquitoes, now accepted as incontrovertible the results of the experiments of the Commission. He followed with interest many of the experiments, and as a member of the Commission saw most of these cases, which he had no hesitation in pronouncing typical cases of yellow fever. A fact which impressed him forcibly was the absolute control of the epidemic by Dr. Reed. The cases would develop or not as he wished. He does not think that the mosquito should be called the Culex fasciatus. Giles' description of the Culex tiniads mosquito agrees more closely than with the Culex fasciatus. He describes the difference between them. He is inclined to consider them a genus apart because they lay different eggs.

Dr. C. Finlay, Havana, expressed his admiration for the work of the Commission. He believes that this session of the Congress will go down in history as of great importance, and that the differences between his opinion and that held by the Commission will disappear in the course of time. He states that they were based on the fact that he investigated with three varieties of mosquitoes, while the Commission has been restricted to one variety; that the board was placed upon better footing for obtaining satisfactory results; that the negative result obtained by the inoculation of mosquitoes of short infection should not induce the Commission or the board to make such hard and biased rules as are evidenced in its conclusions.

Dr. Reed, in conclusion, said he was profoundly impressed with the interest and attention given to these experiments. In regard to the moral aspect of the case, he did not think that any one appreciated the position in which he found himself—the difficulties that beset his path. The first experiment was made on a member of the board, Dr. Carroll. The senior member expected to take his bite in turn, but was unexpectedly called north. As no animal could be given the disease, and it was useless to follow the previous indefinite experiments, it was absolutely necessary to make these experiments on human subjects, or otherwise volumes could have been written and discussed and yet we would have been no nearer the truth than at first. No progress could have been made toward an exact knowledge of the disease unless human subjects had been used. All experiments were performed upon persons who had given their free consent.

In reference to the remarks of Dr. Holbeck, of Charleston, the disinfection of vessels should by no means be dispensed with, but only of such articles as bedding and clothing, though it is necessary to get rid of the mosquitoes, and this simplified the process of disinfection.

In regard to the remarks of Dr. Gutierrez, in reference to the name of the mosquito, Dr. Howard, of Baltimore, told him that Culex fasciatus is identical with Culex tiniads as described by Giles. Theobolt separates Culex tiniads from the genus Culex and places it in a new genus, Stegamina. These lay their eggs in a peculiar way, and there is also a difference in the anterior claws of the male insect from those of the other Culex. There is also a difference in the larva of the Culex fasciatus. It is very interesting also to note the fact that this is the very mosquito that Dr. Finlay used in his experiments, and that this particular mosquito does not belong to the genus Culex, therefore malaria has a genus of its own, Anopheles, and yellow fever the genus Stegamina.

Resolutions on Dr. Wm. Pepper.

A committee consisting of Drs. R. G. Curtin and Hudson Makuen, both of Philadelphia, was appointed to prepare resolutions on the death of Dr. Wm. Pepper. It reported the following, which was adopted:

It is with unfeigned sorrow that we mourn the death of our honored president, Dr. Wm. Pepper, who organized the Pan-American Medical Congress, and who so ably and successfully presided over the first two meetings. To his wise supervision is due much of the success of the Congress since its inception. At this time we especially feel the loss of his guiding hand and his executive ability to help us in achieving still greater success. In our grief we are not alone, for many and various enterprises are hampered by the absence of his painstaking care. Let his example of untiring industry and the memory of his useful life spur us on to carry out the important work planned by our beloved president, Dr. Wm. Pepper. May the crown of glory which he richly deserves be his, is the prayer of his associates of the Pan-American Medical Congress.

Officers for 1903.

The next place of meeting is Buenos Ayres, in 1903. The committee representing the United States consists of Drs. C. A. L. Reed, Cincinnati, Ohio, president; A. Vander Veer, Albany, N. Y., vice-president; Ramon Guiteras, New York City, secretary, and H. L. E. Johnson, Washington, D. C., treasurer.

Attendance from the U. S.

The following registered from the United States: E. W. Andrews, Chicago; T. E. Bamford, New York; T. J. Bennett, Austin, Tex.; C. E. Bruce, New York; H. T. Byford, Chicago; S. Carnes, Washington, D. C.; S. C. Carson, Greensboro, Ala.; H. D. W. Carvelle, Manchester, N. H.; William Chandler, South Orange, N. J.; T. D. Crothers, Hartford, Conn.; Roland C. Curtin, Philadelphia; W. E. B. Davis, Birmingham, Ala.; Thomas McDavitt, St. Paul, Minn.; Arthur B. Duel, New York City; W. H. Earles, Milwaukee, Wis.; D. S. Fairchild, Clinton, Ia.; W. H. Findley, Altoona, Pa.; J. S. Foote, Omaha, Neb.; Louis Frank, Milwaukee, Wis.; Mamel R. Gatell, New York City; Frank Greene, Chicago; Jefferson D. Griffith, Kansas City, Mo.; J. F. B. Guillet, Ocala, Fla.; Ramon Guiteras, New York City; Henry Hammond, Killingly, Conn.; J. D. C. Hoit, Elmwood, Ill.; J. W. Holiday, Burlington, Ia.; E. Hollinghead, of New Jersey; William Jepson, Sioux City, Ia.; H. L. E. Johnson, Washington, D. C.; H. A. Kornemann, Newark, N.J.; George N. Kreider, Springfield, Ill.; Frank Le Morque, West Virginia; Hudson Makuen, Philadelphia; W. P. Manton, Detroit; J. L. Medina, New York City; H. Mitchel, Asbury Park, N.J.; J. B. McGaughey, Winona, Minn.; L. H. Montgomery, Chicago; N. C. Morse, Eldora, Ia.; J. Mullen, Houston, Tex.; Henry Parker Newman, Chicago; Arthur H. Nichols, Boston; Wm. P. Nicholson, Atlanta, Ga.; George H. Noble, Atlanta, Ga.; A. M. Phelps, New York City; S. Pilcher, Brooklyn, N. Y.; Nestor Ponce de Leon, New York; J. Porter, Key West, Fla.; W. E. M. Ranchous, Columbus, Ohio; A. J. Read, Battle Creek, Mich.; C. Roberts, New York; Reginald Sayre, New York City; George H. Simmons, Chicago; A. G. Sprague, River Point, R. I.; Thomas L. Stedman, New York City; J. H. Stoddard, Pueblo, Colo.; C. B. Sweeting, Key West, Fla.; F. C. Valentine, New York City; W. A. K. Vance, Bristol, Tenn.; A. Vander Veer, Albany, N. Y.; E. Van Hood, Ocala, Fla.; B. T. Whitmore, New York City; M. C. Wyeth, U. S. A.; Walter Wyman, Washington, D. C.; Henry B. Young, Burlington, Ia.

(To be Continued.)

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

Section on Gynecology.

Meeting January 17.

John C. DaCosta, M. D., Chairman.

Cancer of the Cervix and Pelvis Following Supravaginal Hysterectomy.

Dr. Chas. P. Noble read a paper, on this topic. He said that one of the arguments used in favor of total as against supravaginal hysterectomy for fibroid tumors of the uterus or for extensive inflammatory disease of that organ and its appendages, was that in a definite percentage of cases the cervix, if left in the pelvis, subsequently becomes the seat of carcinoma. A few cases of this kind have been reported, and these are always referred to in papers written from this standpoint, so that it is made to appear that there is considerable risk of carcinoma if the supravaginal hysterectomy is employed instead of total hysterectomy. His own experience, which embraced more than 175 supravaginal hysterectomies for fibroid tumors, and a larger number for inflammatory diseases of the appendages, had not borne out this contention, but on the contrary indicates that carcinoma following supravaginal hysterectomy is an exceedingly rare occurrence. On March 7, 1895, the following case was operated on in his own service at the Kensington Hospital for Women. Mrs. D., aged 35, who had had three children and one miscarriage, had suffered from menorrhagia and had had numerous attacks of pelvic peritonitis. Abdominal section disclosed a fibroid tumor of the uterus the size of a cocoa-nut, a left ovarian cyst and a right hydrosalpinx. These structures were adherent in the pelvis and the tumors were edematous and infiltrated with inflammatory products. Supravaginal hysterectomy was performed, removing the ovarian tumor and appendages, the fibroid tumor and the corpus uteri. The atypical condition of the tumor was noted but attributed to the repeated attacks of peritonitis, from which the patient had suffered. She made a fairly good recovery, and was discharged from the hospital on April 7. Unfortunately no detailed study of the specimen was made and no microscopic sections were examined.

Four months after the operation the patient began to bleed irregularly from the vagina. Eight months after the operation Dr. Applebach made a pelvic examination and found that the pelvis, vagina and cervix were involved in an extended carcinoma. The patient died a few months later, about one year after the operation. As the specimens from this case were not examined it is impossible to say definitely which was the primary seed of the carcinoma, but in view of the history both before and after the operation there is good reason to believe that a carcinoma of the body of the uterus existed as a complication of the fibroid tumor at the time of the operation, and that this disease had already involved the broad ligament when the hysterectomy was performed. This case was reported not so much because of its value in itself as because of the negative value of his own experience with reference to the appearance of carcinoma in the cervix left after a supravaginal hysterectomy. This was the only one which he had made and in this there was every reason to believe that unrecognized carcinoma existed at the time of operation.

Ovarian Cyst: Suppuration: Hematocele.

Dr. Geo. Erety Shoemaker read a paper on this subject. D., married, aged 48, with eight children and no miscarriages, was a patient of Dr. Fries. She had been tapped several weeks before coming under observation, and ten quarts of thin chocolate-colored fluid removed, disclosing a remaining mass in the upper abdomen. The abdomen had rapidly become again distended on her admission to the Presbyterian Hospital, and then contained a large cystic tumor which was somewhat irregular on its upper surface and presented many of the characteristics of an ovarian cyst, except that a possible origin in the upper abdomen could not be disproved. Eighteen months before, when her last child was born, no tumor was felt. The patient was very stout, was jaundiced, and had a very irritable stomach, while a trace of albumin and a few hyaline casts appeared in the urine. At the operation the tumor was found to be a cyst of the left ovary and was removed. The ovary of the opposite side contained a small hematogenous cyst and was removed with the hydrosalpinx of the same size. The semi-solid contents of chocolate-colored fluid measured about 10 quarts. Adhesions were marked over the anterior surface of the tumor, probably owing to the tapping. There were considerable adhesions to the transverse and descending colon and a considerable stripping of the peritoneal cover occurred on the left side. Some uncertainty was felt as to the complete control of hemorrhage from an area in the mesocolon near the sigmoid flexure. There was some tendency to subperitoneal bleeding; as it did not appear to be persistent or definite after some hesitation irrigation with hot saline solution was used and the abdomen closed. There was much fatty deposit behind the peritoneum and about the large intestine, the patient being somewhat obese. She recovered slowly, after much vomiting for the first day or two, a symptom to which she had been subject for some time. The patient was most unruly and difficult to manage. The slight jaundice persisted. About a week after the operation a pelvic examination was made and there was found, distending the tissues around and between the rectum and the vagina, and on both sides of the uterus, a more or less indurated mass. This became quite hard, but about four weeks after the operation gradually softened and obscure fluctuation was obtained behind the cervix, the temperature being at this time irregular, with some sweating and a feeling of rectal pressure. The diagnosis of pelvic hematocele which was undergoing suppuration was made. The source of the blood was thought to have been the vessels in the mesocolon and in the neighborhood of the sigmoid which had been injured in the separation of the strong adhesions in this region. Incision immediately behind the cervix gave exit to several ounces of blood and of pus with small black clots. The cavity from which this came was shallow, very irregular in outline, and appeared to contain shreds of blood-clots which had not yet broken down. A drainage-tube was inserted and iodoform gauze packed in the vagina. Under careful irrigation the discharge became rapidly diminished and the patient's temperature became normal and remained so. Complete recovery followed. This collection of blood must have been subperitoneal, as it surrounded and more or less fixed the rectum. After it had become consolidated the pressure on the rectum was a source of great distress to the patient, who complained rather of pressure than of pain. She had considerable difficulty in having a stool, owing to the presence of this induration. The vaginal incision was made about five weeks after the laparotomy. The jaundice disappeared in about eight weeks. She was discharged in good condition.

Salpingitis: Obscure Localized Symptoms.

DR. SHOEMAKER also reported this case: H. H., 25 years old, single, colored, was admitted to the wards of the Presbyterian Hospital with a history as follows: Her previous health had been good. She menstruated normally. In August, 1900, three months before admission, she had an attack of abdominal inflammation characterized by vomiting, pain in the right abdomen opposite the umbilicus, slight jaundice, and irregular temperature—103 degrees. She slowly recovered, but afterward had more or less distress in the lower abdomen, referred to the region of the appendix. This distress was increased by lifting and working. Two days before her admission the patient, while menstruating, had gotten her feet wet washing a pavement. The next day she had chilliness, great pain all over the abdomen, vomiting, constipation and elevated temperature. She was admitted to the surgical ward with the supposed diagnosis of appendicitis. The doctor was asked to see her in consultation with the surgeon on duty. When seen by him she had been ill five days. The tongue was coated a dirty white, somewhat dry, and while vomiting had been severe it had ceased. There was slight jaundice, the face was anxious and the greatest pain complained of was in the region of the gall-bladder; the epigastric tenderness, however, was most marked on both sides, just above Poupart's ligament, and the muscular rigidity, while not marked, was present in the left abdominal quadrant, and the tenderness extended up over the region of the appendix. The tenderness being too great for a pelvic examination, ether was given for diagnosis, with the result that nothing could be felt in the upper abdomen and no mass in the region of the appendix. In Douglas's cul-de-sac were felt prolapsed coils of intestine which, when displaced, gave the sensation of the parting of very slight adhesions. Both tubes and ovaries were slightly enlarged and thickened; the uterus was restricted in mobility and forward.

The diagnosis of acute salpingitis was made, with the reservation of a possibility of a coincident involvement of the appendix. On this diagnosis the patient was transferred to the gynecological department, under his care. As the attack was five days old, the temperature range was improving, vomiting had ceased, and the pulse was good, ranging below 40. The expectant treatment was continued and ice was ordered over the lower abdomen. During the next week the point of greatest tenderness varied from the epigastrium to McBurney's point, and across the whole lower abdomen. At times palpation of the epigastrium was impossible. The muscular rigidity, however, disappeared in the lower abdomen, and the general condition gradually resumed its normal appearance, except for the slight pelvic tenderness. The patient was confined to bed and the attack allowed to subside, and, five weeks after the onset, abdominal section was performed. Owing to the slight jaundice, the persistent high location of pain and tenderness, and the rather slight situation of the inclination, it was supposed that the appendix would be found involved with the tubes. The incision was, therefore, made one inch to the right of the median line and through the right rectus muscle. The inflammatory disease was found to involve chiefly the uterus and adnexa, the appendix dipping down into the pelvis, however, and was slightly adherent by its tip to the enlarged right ovary, but its walls were not inflamed and there were no adhesions throughout its continuity. It was, therefore, not removed. There was capillary congestion and a roughening of the peritoneum over several coils of small intestine in the lower abdomen. The omentum was slightly adherent to the anterior pelvic brim. Both tubes and ovaries were buried in dense adhesions. The right tube was contorted and the uterine extremity normal for about an inch. The fimbriated extremity was completely destroyed by inflammation. Two pockets of inflammatory material occupied the lumen of the tube, the outer one containing yellowish pus in flakes, the inner one swollen rugæ covered with flakes of inflammatory lymph. The right ovary was buried with the tube and under the inflammatory exudate contained a cyst of 1½ inches in diameter. Its contents were thickened and bloody fluid. The tube and ovary were with some difficulty freed, tied off and removed. The left ovary, when freed from adhesions, was found to be nearly normal in size. The left tube was inflamed and three-fourths of an inch in diameter. After separation from its bed of adhesions, bloody, semipurulent material could be squeezed from its outer opening. There was free oozing from the fimbriæ and from the adhesions, even after irrigation and sponge pressure. The lifting of the tube was considered unsafe on account of the free oozing and the danger of infection from the tubal contents. It was, therefore, removed with a portion of the corresponding ovary, the remaining portion of the ovary being left with the hope of maintenance of some function. Irrigation with saline solution, careful peritoneal toilet of the wound by through-and-through silkworm gut sutures and catgut to the aponeurosis was followed by satisfactory recovery.

DR. C. P. NOBLE cited the case of a patient treated for salpingitis by an able medical man. She had had three recurrent attacks in his hands, when the speaker was called in consultation. Three physicians agreed that the patient had salpingitis, so he operated. The appendix was in the pelvis, was inflamed, and agglutinated in a mass of exudate was the appendix, the ovary and tube. Under these circumstances a correct diagnosis was impossible; the exudate was in the pelvis, where it would be found if the disease was salpingitis. In the appendicular region the parts felt normal on palpation. Under these circumstances it was impossible to make a diagnosis. In the case referred to by Dr. Shoemaker, where the tubes were lay their eggs in a peculiar way, and there is also a difference in the anterior claws of the male insect from those of the other Culex. There is also a difference in the larva of the Culex fasciatus. It is very interesting also to note the fact that this is the very mosquito that Dr. Finlay used in his experiments, and that this particular mosquito does not belong to the genus Culex, therefore malaria has a genus of its own, Anopheles, and yellow fever the genus Stegamina.

Resolutions on Dr. Wm. Pepper.

A committee consisting of Drs. R. G. Curtin and Hudson Makuen, both of Philadelphia, was appointed to prepare resolutions on the death of Dr. Wm. Pepper. It reported the following, which was adopted:

It is with unfeigned sorrow that we mourn the death of our honored president, Dr. Wm. Pepper, who organized the Pan-American Medical Congress, and who so ably and successfully presided over the first two meetings. To his wise supervision is due much of the success of the Congress since its inception. At this time we especially feel the loss of his guiding hand and his executive ability to help us in achieving still greater success. In our grief we are not alone, for many and various enterprises are hampered by the absence of his painstaking care. Let his example of untiring industry and the memory of his useful life spur us on to carry out the important work planned by our beloved president, Dr. Wm. Pepper. May the crown of glory which he richly deserves be his, is the prayer of his associates of the Pan-American Medical Congress.

Officers for 1903.

The next place of meeting is Buenos Ayres, in 1903. The committee representing the United States consists of Drs. C. A. L. Reed, Cincinnati, Ohio, president; A. Vander Veer, Albany, N. Y., vice-president; Ramon Guiteras, New York City, secretary, and H. L. E. Johnson, Washington, D. C., treasurer.

Attendance from the U. S.

The following registered from the United States: E. W. Andrews, Chicago; T. E. Bamford, New York; T. J. Bennett, Austin, Tex.; C. E. Bruce, New York; H. T. Byford, Chicago; S. Carnes, Washington, D. C.; S. C. Carson, Greensboro, Ala.; H. D. W. Carvelle, Manchester, N. H.; William Chandler, South Orange, N. J.; T. D. Crothers, Hartford, Conn.; Roland C. Curtin, Philadelphia; W. E. B. Davis, Birmingham, Ala.; Thomas McDavitt, St. Paul, Minn.; Arthur B. Duel, New York City; W. H. Earles, Milwaukee, Wis.; D. S. Fairchild, Clinton, Ia.; W. H. Findley, Altoona, Pa.; J. S. Foote, Omaha, Neb.; Louis Frank, Milwaukee, Wis.; Mamel R. Gatell, New York City; Frank Greene, Chicago; Jefferson D. Griffith, Kansas City, Mo.; J. F. B. Guillet, Ocala, Fla.; Ramon Guiteras, New York City; Henry Hammond, Killingly, Conn.; J. D. C. Hoit, Elmwood, Ill.; J. W. Holiday, Burlington, Ia.; E. Hollinghead, of New Jersey; William Jepson, Sioux City, Ia.; H. L. E. Johnson, Washington, D. C.; H. A. Kornemann, Newark, N.J.; George N. Kreider, Springfield, Ill.; Frank Le Morque, West Virginia; Hudson Makuen, Philadelphia; W. P. Manton, Detroit; J. L. Medina, New York City; H. Mitchel, Asbury Park, N.J.; J. B. McGaughey, Winona, Minn.; L. H. Montgomery, Chicago; N. C. Morse, Eldora, Ia.; J. Mullen, Houston, Tex.; Henry Parker Newman, Chicago; Arthur H. Nichols, Boston; Wm. P. Nicholson, Atlanta, Ga.; George H. Noble, Atlanta, Ga.; A. M. Phelps, New York City; S. Pilcher, Brooklyn, N. Y.; Nestor Ponce de Leon, New York; J. Porter, Key West, Fla.; W. E. M. Ranchous, Columbus, Ohio; A. J. Read, Battle Creek, Mich.; C. Roberts, New York; Reginald Sayre, New York City; George H. Simmons, Chicago; A. G. Sprague, River Point, R. I.; Thomas L. Stedman, New York City; J. H. Stoddard, Pueblo, Colo.; C. B. Sweeting, Key West, Fla.; F. C. Valentine, New York City; W. A. K. Vance, Bristol, Tenn.; A. Vander Veer, Albany, N. Y.; E. Van Hood, Ocala, Fla.; B. T. Whitmore, New York City; M. C. Wyeth, U. S. A.; Walter Wyman, Washington, D. C.; Henry B. Young, Burlington, Ia.

(To be Continued.)

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

Section on Gynecology.

Meeting January 17.

John C. DaCosta, M. D., Chairman.

Cancer of the Cervix and Pelvis Following Supravaginal Hysterectomy.

Dr. Chas. P. Noble read a paper, on this topic. He said that one of the arguments used in favor of total as against supravaginal hysterectomy for fibroid tumors of the uterus or for extensive inflammatory disease of that organ and its appendages, was that in a definite percentage of cases the cervix, if left in the pelvis, subsequently becomes the seat of carcinoma. A few cases of this kind have been reported, and these are always referred to in papers written from this standpoint, so that it is made to appear that there is considerable risk of carcinoma if the supravaginal hysterectomy is employed instead of total hysterectomy. His own experience, which embraced more than 175 supravaginal hysterectomies for fibroid tumors, and a larger number for inflammatory diseases of the appendages, had not borne out this contention, but on the contrary indicates that carcinoma following supravaginal hysterectomy is an exceedingly rare occurrence. On March 7, 1895, the following case was operated on in his own service at the Kensington Hospital for Women. Mrs. D., aged 35, who had had three children and one miscarriage, had suffered from menorrhagia and had had numerous attacks of pelvic peritonitis. Abdominal section disclosed a fibroid tumor of the uterus the size of a cocoa-nut, a left ovarian cyst and a right hydrosalpinx. These structures were adherent in the pelvis and the tumors were edematous and infiltrated with inflammatory products. Supravaginal hysterectomy was performed, removing the ovarian tumor and appendages, the fibroid tumor and the corpus uteri. The atypical condition of the tumor was noted but attributed to the repeated attacks of peritonitis, from which the patient had suffered. She made a fairly good recovery, and was discharged from the hospital on April 7. Unfortunately no detailed study of the specimen was made and no microscopic sections were examined.

Four months after the operation the patient began to bleed irregularly from the vagina. Eight months after the operation Dr. Applebach made a pelvic examination and found that the pelvis, vagina and cervix were involved in an extended carcinoma. The patient died a few months later, about one year after the operation. As the specimens from this case were not examined it is impossible to say definitely which was the primary seed of the carcinoma, but in view of the history both before and after the operation there is good reason to believe that a carcinoma of the body of the uterus existed as a complication of the fibroid tumor at the time of the operation, and that this disease had already involved the broad ligament when the hysterectomy was performed. This case was reported not so much because of its value in itself as because of the negative value of his own experience with reference to the appearance of carcinoma in the cervix left after a supravaginal hysterectomy. This was the only one which he had made and in this there was every reason to believe that unrecognized carcinoma existed at the time of operation.

Ovarian Cyst: Suppuration: Hematocele.

Dr. Geo. Erety Shoemaker read a paper on this subject. D., married, aged 48, with eight children and no miscarriages, was a patient of Dr. Fries. She had been tapped several weeks before coming under observation, and ten quarts of thin chocolate-colored fluid removed, disclosing a remaining mass in the upper abdomen. The abdomen had rapidly become again distended on her admission to the Presbyterian Hospital, and then contained a large cystic tumor which was somewhat irregular on its upper surface and presented many of the characteristics of an ovarian cyst, except that a possible origin in the upper abdomen could not be disproved. Eighteen months before, when her last child was born, no tumor was felt. The patient was very stout, was jaundiced, and had a very irritable stomach, while a trace of albumin and a few hyaline casts appeared in the urine. At the operation the tumor was found to be a cyst of the left ovary and was removed. The ovary of the opposite side contained a small hematogenous cyst and was removed with the hydrosalpinx of the same size. The semisolid contents of chocolate-colored fluid measured about 10 quarts. Adhesions were marked over the anterior surface of the tumor, probably owing to the tapping. There were considerable adhesions to the transverse and descending colon and a considerable stripping of the peritoneal cover occurred on the left side. Some uncertainty was felt as to the complete control of hemorrhage from an area in the mesocolon near the sigmoid flexure. There was some tendency to subperitoneal bleeding; as it did not appear to be persistent or definite after some hesitation irrigation with hot saline solution was used and the abdomen closed. There was much fatty deposit behind the peritoneum and about the large intestine, the patient being somewhat obese. She recovered slowly, after much vomiting for the first day or two, a symptom to which she had been subject for some time. The patient was most unruly and difficult to manage. The slight jaundice persisted. About a week after the operation a pelvic examination was made and there was found, distending the tissues around and between the rectum and the vagina, and on both sides of the uterus, a more or less indurated mass. This became quite hard, but about four weeks after the operation gradually softened and obscure fluctuation was obtained behind the cervix, the temperature being at this time irregular, with some sweating and a feeling of rectal pressure. The diagnosis of pelvic hematocele which was undergoing suppuration was made. The source of the blood was thought to have been the vessels in the mesocolon and in the neighborhood of the sigmoid which had been injured in the separation of the strong adhesions in this region. Incision immediately behind the cervix gave exit to several ounces of blood and of pus with small black clots. The cavity from which this came was shallow, very irregular in outline, and appeared to contain shreds of blood-clots which had not yet broken down. A drainage-tube was inserted and iodoform gauze packed in the vagina. Under careful irrigation the discharge became rapidly diminished and the patient's temperature became normal and remained so. Complete recovery followed. This collection of blood must have been subperitoneal, as it surrounded and more or less fixed the rectum. After it had become consolidated the pressure on the rectum was a source of great distress to the patient, who complained rather of pressure than of pain. She had considerable difficulty in having a stool, owing to the presence of this induration. The vaginal incision was made about five weeks after the laparotomy. The jaundice disappeared in about eight weeks. She was discharged in good condition.

Salpingitis: Obscure Localized Symptoms.

Dr. Shoemaker also reported this case: H. H., 25 years old, single, colored, was admitted to the wards of the Presbyterian Hospital with a history as follows: Her previous health had been good. She menstruated normally. In August, 1900, three months before admission, she had an attack of abdominal inflammation characterized by vomiting, pain in the right abdomen opposite the umbilicus, slight jaundice, and irregular temperature—103 degrees. She slowly recovered, but afterward had more or less distress in the lower abdomen, referred to the region of the appendix. This distress was increased by lifting and working. Two days before her admission the patient, while menstruating, had gotten her feet wet washing a pavement. The next day she had chilliness, great pain all over the abdomen, vomiting, constipation and elevated temperature. She was admitted to the surgical ward with the supposed diagnosis of appendicitis. The doctor was asked to see her in consultation with the surgeon on duty. When seen by him she had been ill five days. The tongue was coated a dirty white, somewhat dry, and while vomiting had been severe it had ceased. There was slight jaundice, the face was anxious and the greatest pain complained of was in the region of the gallbladder; the epigastric tenderness, however, was most marked on both sides, just above Poupart's ligament, and the muscular rigidity, while not marked, was present in the left abdominal quadrant, and the tenderness extended up over the region of the appendix. The tenderness being too great for a pelvic examination, ether was given for diagnosis, with the result that nothing could be felt in the upper abdomen and no mass in the region of the appendix. In Douglas's cul-de-sac were felt prolapsed coils of intestine which, when displaced, gave the sensation of the parting of very slight adhesions. Both tubes and ovaries were slightly enlarged and thickened; the uterus was restricted in mobility and forward.

The diagnosis of acute salpingitis was made, with the reservation of a possibility of a coincident involvement of the appendix. On this diagnosis the patient was transferred to the gynecological department, under his care. As the attack was five days old, the temperature range was improving, vomiting had ceased, and the pulse was good, ranging below 40. The expectant treatment was continued and ice was ordered over the lower abdomen. During the next week the point of greatest tenderness varied from the epigastrium to McBurney's point, and across the whole lower abdomen. At times palpation of the epigastrium was impossible. The muscular rigidity, however, disappeared in the lower abdomen, and the general condition gradually resumed its normal appearance, except for the slight pelvic tenderness. The patient was confined to bed and the attack allowed to subside, and, five weeks after the onset, abdominal section was performed. Owing to the slight jaundice, the persistent high location of pain and tenderness, and the rather slight situation of the inclination, it was supposed that the appendix would be found involved with the tubes. The incision was, therefore, made one inch to the right of the median line and through the right rectus muscle. The inflammatory disease was found to involve chiefly the uterus and adnexa, the appendix dipping down into the pelvis, however, and was slightly adherent by its tip to the enlarged right ovary, but its walls were not inflamed and there were no adhesions throughout its continuity. It was, therefore, not removed. There was capillary congestion and a roughening of the peritoneum over several coils of small intestine in the lower abdomen. The omentum was slightly adherent to the anterior pelvic brim. Both tubes and ovaries were buried in dense adhesions. The right tube was contorted and the uterine extremity normal for about an inch. The fimbriated extremity was completely destroyed by inflammation. Two pockets of inflammatory material occupied the lumen of the tube, the outer one containing yellowish pus in flakes, the inner one swollen rugæ covered with flakes of inflammatory lymph. The right ovary was buried with the tube and under the inflammatory exudate contained a cyst of 1½ inches in diameter. Its contents were thickened and bloody fluid. The tube and ovary were with some difficulty freed, tied off and removed. The left ovary, when freed from adhesions, was found to be nearly normal in size. The left tube was inflamed and three-fourths of an inch in diameter. After separation from its bed of adhesions, bloody, semipurulent material could be squeezed from its outer opening. There was free oozing from the fimbriæ and from the adhesions, even after irrigation and sponge pressure. The lifting of the tube was considered unsafe on account of the free oozing and the danger of infection from the tubal contents. It was, therefore, removed with a portion of the corresponding ovary, the remaining portion of the ovary being left with the hope of maintenance of some function. Irrigation with saline solution, careful peritoneal toilet of the wound by through-and-through silkworm gut sutures and catgut to the aponeurosis was followed by satisfactory recovery.

Dr. C. P. Noble cited the case of a patient treated for salpingitis by an able medical man. She had had three recurrent attacks in his hands, when the speaker was called in consultation. Three physicians agreed that the patient had salpingitis, so he operated. The appendix was in the pelvis, was inflamed, and agglutinated in a mass of exudate was the appendix, the ovary and tube. Under these circumstances a correct diagnosis was impossible; the exudate was in the pelvis, where it would be found if the disease was salpingitis. In the appendicular region the parts felt normal on palpation. Under these circumstances it was impossible to make a diagnosis. In the case referred to by Dr. Shoemaker, where the tubes were thickened and could be definitey made out, he thought the diagnosis was much more simple.

Dr. Shoemaker, in closing the discussion, said, in regard to the post-operative hemorrhage that he thought it was subperitoneal for the probable reason that, on opening the collection, it was found occupying the median line, involving Douglas's pouch. In one case the mass was as large as a child's head, obliterating the vagina behind but not involving the sides of the uterus, vagina or rectum. In two other cases, occurring recently, the Douglas pouch had been opened and there the same definite location of the collection in the median line found. Subperitoneal hemorrhage is quite possible and is sometimes seen in operations where the vessel is low down, particularly in extrauterine pregnancy. Sometimes the whole floor of the pelvis has filled with blood and there is considerable difficulty in controlling the hemorrhage.

His second case was not reported as one of pelvic abscess due to appendicitis, but as a case of salpingitis with some few symptoms of appendicitis, probably reflex. He had been in the habit of examining the appendices and in 10 per cent. of all cases of abdominal section also removed the appendix.

The differential diagnosis can usually be made between appendicitis and salpingitis by the menstrual history being abnormal in the case of salpingitis; by the normal feeling of the tubes when examination is conducted under the influence of ether, bimanual examination demonstrating the normal condition of the tubes; by the lower situation of the inflammatory mass in case it is tubal—this is particularly demonstrable through the rectum; by the characteristic history of appendicitis, the short onset without the causes which would tend to produce salpingitis, the sharp onset of localized pain and muscular rigidity being alike in both conditions. Vomiting is not common in salpingitis as it is in the intestinal lesion, and the pain is referred to the epigastrium in appendicitis but not in salpingitis. In the case reported this symptom made the diagnosis more difficult.

CHICAGO SOCIETY OF INTERNAL MEDICINE.

Regular Meeting held January 15.

The President, Dr. John A. Robison, in the chair.

Chlorosis.

Dr. Gustav Fuetterer read a paper on "Chlorosis, Its Diagnosis and Treatment, and Its Relation to Tuberculosis and to Round Ulcer of the Stomach." This will be printed in The Journal.

The Blood in Anemia.

Dr. Joseph A. Capps followed with "A Preliminary Report on Some Observations of the Blood in Anemia." He said that, in order to fully understand the pathology of the various anemias, we must definitely determine whether the destruction of blood is general or selective in character; whether the blood loss takes place in the serum or corpuscles; whether the cell in giving up its hemoglobin also loses its protoplasm. The brunt of the attack is undoubtedly borne by the corpuscles, for however important a rôle the serum may play in its chemical functions, it undergoes relatively slight physical changes in either health or disease. No material alteration takes place in the specific gravity of the blood serum in most of the severe pathologic conditions, with the exception of hydremic and post-hemorrhagic states, while the influence of the physiologic taking in and execretion of liquids is slight (Schmaltz). The researches of Hammerschlag, V. Limbeck, and others have taught us that varations in specific gravity of red corpuscles, e. g., changes in their chemical affinity for iron, of the blood as a whole depend primarily on disturbances of the changes in their number and their size and changes in their ability to absorb or lose water.

A priori an increase or diminution of the hemoglobin might be explained entirely on the basis of chemical affinity without regard to the size of the cell body, and this view is held by many hematologists. From this standpoint we may consider that in anemia qualitative changes of a degenerative character lessen the power of the corpuscle to take up iron. On the other hand, there is much evidence to show that quantitative as well as qualitative changes take place in the cell and influence the hemoglobin content.

Several methods have been used to calculate the size of the red cells. Measurement of the cell diameter with a micrometer ruling has afforded fair results, but this gives one dimension only. The depth can be told roughly by the presence or absence of a central light area in the red corpuscle which takes a faint stain; or by observing the thickness of the disc when lying on edge in a fresh drop. These methods obviously are inaccurate and unreliable.

The centrifuge yields the only satisfactory results, taken in conjunction with a careful count of the red cells with a Thoma-Zeiss instrument. The percentage volume of the red cells as a whole, as obtained from the graduated capillary tube, is divided by the percentage number of red corpuscles, which gives the percentage volume of the individual corpuscle.

For this quotient he is aware of no term that has been employed; he therefore suggested the name of "Volume Index," which is self-explanatory and is easily associated with the familiar term "color index." Thus a reading of 45 on the tube=90 per cent.; the red cells number by count 3,750,000 or 75 per cent.; then 90/75=1.20 volume index or an increase of 20 per cent. above the normal in the volume of the average cell.

It is generally believed that the erythrocytes are smaller than normal in chlorosis and larger than normal in pernicious anemia, but very few observers have accurately measured these variations and studied their relations to the hemoglobin and blood as a whole.

Herz (*Virch. Archiv*) claims to have found acute swelling of the cells without a rise in the hemoglobin after hemorrhage and peritonitis. He says that the cells in chlorosis are swollen or normal, never small. A chronic hypertrophy was found by him in Hodgkin's disease and in cachexia, while an atrophy of cells occurred in certain secondary anemias. Von Limbeck observed enlargement of the cells by measurement of diameters in catarrhal jaundice.

Thus we see that in chlorosis and most secondary anemias we have a lowering not only of the color index, but of the volume index as well. Without doubt the color loss precedes in time the loss in size and is always much more pronounced. In one case the color index fell to .45, whereas the volume index never fell below 5.7. Mild cases, or those recovering, exhibit a normal volume index while the hemoglobin is still deficient.

The process of impoverishment seems very similar in chlorosis, and the so-called secondary anemias except for the tendency of the red corpuscles in chlorosis to resist more successfully a reduction in number. As a result of this fact recovery is more rapid in chlorosis. There are, however, many cases of chlorosis where the number of cells and the volume index are much lowered, and these patients get well slowly, resembling secondary anemias. Conversely we must bear in mind instances of secondary anemia that are poor in hemoglobin, but almost normal in the number of red cells. Many examples occur, therefore, where it is impossible to state from the blood examination whether they are chlorotic or of the secondary type, and lead us to believe that chlorosis is but one of the clinical varieties of secondary anemia.

In pernicious anemia, instead of a shriveling of the red cell, we have a hypertrophy to correspond with the heightened color index. This hypertrophy does not simply *keep up* with the high color index—it nearly always surpasses it by a safe margin. Since the most sweeping destruction of red corpuscles takes place in this disease, we may look upon this increased size of the remaining cells as a sort of compensatory hypertrophy that largely enhances their efficiency in carrying on the work of oxidation. The highest volume index was 1.93, which indicates an average cell capacity almost twice the normal. This makes it easier to understand how life can be maintained with 500,000 red corpuscles or less to the cubic millimeter.

Bearing on this idea of compensatory hypertrophy he has observed that a similar process tends to operate in *all forms* of anemia where the red cells have been depleted to 2,000,000 or less. As the count falls below this point we see more and more macrocytes, the volume index tends to increase, the color index rises until both the latter may be normal or above. Hence it is possible for a secondary anemia which has been characterized by a steady loss in cell size and color to reach such a low point that the cells must grow larger in order to sustain life.

There are many other conditions where a knowledge of the volume of the cells may be able to throw some light on pathology, such as jaundice, hydremias, cyanosis and hemorrhage, and these he hopes to study before completing his report.

A study of 14 cases of chlorosis shows that the red corpuscles in all cases have a smaller average diameter than in normal blood. The color index is constantly very low, while the volume index is decreased to a less degree.

The red cells in 24 cases of secondary anemia are also subnormal in diameters. The color index is not so low as in chlorosis. The volume index falls also, but never so much as the color.

The size of the corpuscles in 17 cases of leukemia and the relation of hemoglobin to volume is essentially the same as in secondary anemia. Thirty-one cases of pernicious anemia give a decided increase in the average diameter of the cells. The color index is high and the volume index still higher.

Hydriatics in the Treatment of Chlorosis.

Dr. G. W. McCaskey, Fort Wayne, Ind., read a paper on this subject. He especially disclaimed any intention of advocating hydrotherapy as an exclusive method of treatment, but urged its careful use in selected cases as a most valuable aid. The treatment, he maintained, should be based on a proper conception of the principal pathologic facts, among which were mentioned the oligochromemia, oligocythemia and oligemia. Especial stress was laid on the oligemia as not being fully recognized in dealing with chlorosis, and as indicating a great impairment of the hematogenic organs. Because of the marked decrease in the total mass of blood which undoubtedly exists the blood count may be normal with a serious degree of oligemia. The weakness of the heart with more or less dilatation; a general lowering of the blood pressure because of the heart conditions and vasomotor states; the resulting impairment of function of all the principal organs as a necessary result of the preceding conditions; and the retention of subcutaneous and intravisceral fat and hypoazaturia as a result of defective oxidation and lowered metabolism; and hypoplasia of cardiovascular and genital organs the common embryonic origin of which from the mesoblast was pointed out as a possibly significant fact, furnish the principal indications for therapeutic procedure.

While the administration of iron was advocated, the exceedingly small amount absorbed, coupled with the better therapeutic results claimed from tremendously large daily doses, points to an indirect action of the iron upon the alimentary tract.

The rest treatment in conjunction with iron, the importance of which most recent authorities emphasize, was pointed out as an important factor in permitting recuperation of cardiovascular tone, and in so doing improving the functions of the digestive organs and of the red bone-marrow upon which hematogenesis is absolutely dependent. Some recent writers report cases treated by rest alone, without iron, with favorable results. The writer believes that there is a radical fault in the organ concerned in making red blood cells—which in the human subject is the exclusive function of the red bone-marrow and that the treatment must be directed toward improving the functional activity of this important tissue. The quality of chlorotic blood is the same as that produced by overworked blood-making organs, the parallelism with the final stage of post-hemorrhagic anemia being especially striking. No single therapeutic measure can so directly influence the nutrition and functional activity of the bone-marrow as hydrotherapy. Its anatomical surroundings remove it from all but indirect methods, and after supplying abundance of iron with such a degree of rest as is indicated, forced feeding and special treatment of any organ that may need it, the indirect results of hydriatic measures can favorably modify the bone-marrow in accordance with well known physiologic laws. The observations of Schüller on the vessels of the pia mater after thermal stimulation of the skin; of Naumann, who demonstrated the partial reflex character of these phenomena, and of Winternitz, whose plethysmographic tracings demonstrated the increased volume and tension of blood in areas removed from the direct impress of cold and heat, were cited as a physiologic basis of hydriatic treatment, concerning the efficacy of which the writer has satisfied himself by a considerable personal experience, supporting the views of Struempell, Winternitz, Immermann, Baruch, and others.

Various methods are available, such as the full bath, spray, douche, etc., the guiding principles being to use that degree of stimulation from which the patient will show a healthy reaction, and to use cold very guardedly and as a rule preceding its application by a storage of heat which will permit of the stimulating and tonic influences of cold without resulting depression.

Chlorosis and Metabolism.

Dr. Fenton B. Turck followed with a paper in which he discussed metabolism and the advent of puberty at considerable length. He likewise dwelt on Herring's view of metabolism and its possible applications, and then passed on to a consideration of the relation of metabolism to function. The selective power of cells and the assimilation of inorganic compounds were mentioned. Relapses and failures of treatment by iron were largely due, in his opinion, to the non-recognition of the important rule of metabolism. He detailed his observations on methods of treatment based upon physiologic laws.

Dr. Frank Billings stated that chlorosis occurs in young women somewhere between 13 and 14 and 22 years of age, on the average. It also exists in young men at that age, but the majority of writers do not accept this. Men in whom chlorosis occurs are of a feminine type, and show it in their physique. Chlorosis occurs in girls where there is a large number in the family, though there are exceptions to this. Dr. Billings touched briefly on the different theories that have been advanced regarding chlorosis. If it is a question of metabolism, why does chlorosis select girls? It is a disease one finds in all climates and under all conditions of life. He has seen quite as many cases among servant girls as among others, and has had a large number of cases among the well-to-do. He does not think there is any hygienic basis for chlorosis. It is not due to impaired nutrition, because it occurs among the children of the rich as well as those of the poor. When he had charge of ward 24, in the Cook County Hospital, he had on an average one case of chlorosis in every fifty patients.

In the treatment, he mentioned beef juice. His objection to it is that patients soon disliked it. To take a pint of beef juice every day requires not only great moral force on the part of the patients, but considerable persuasion by the physician to get them to do it. More people can afford milk than the juice which comes from five pounds of beef. He has gone on year after year, until simply at sea, so to speak, as to whether one preparation of iron is any better than another. On the whole, however, he considers the old tincture of iron the best, because it contains hydrochloric acid. It can be given in good doses, say five or ten, or even fifteen or thirty minims. By diluting the iron with pure glycerin, the patients do not object to it, and they feel and do better on *tincture* of iron than upon any other preparation.

Dr. James B. Herrick said that there are many cases of chlorosis unrecognized, consequently untreated, and a great many, though recognized, are neglected by the patients themselves, or by the families, and allowed to go untreated. This is important, because untreated chlorosis may give rise to serious results. It is probable that a permanent impression is made on these patients that is never removed. Trousseau made the statement that when a patient had well-developed chlorosis, the impression made on her was never eradicated, and it was such a patient who, in later years, became nervous, neurasthenic or prematurely old, so that it was very important that the cases should be recognized early and properly and promptly treated. He emphasized the importance of watching patients for a long period of time. The greatest difficulty he has had in treating cases of chlorosis is to get them to return to him for observation for as long a period as he desires. As soon as these patients improve a little, and feel so much better, many of them believe themselves fully recovered, consequently the physician sees no more of them, even though the nature of the disease is fully explained to them.

He regrets the tendency that prevails, to look upon chlorosis as a secondary anemia. It can not be denied that the blood findings are those of secondary anemia. If chlorosis is to be considered as a secondary anemia, it is a class by itself, and it is a secondary anemia in the sense that pernicious anemia is secondary, but physicians do not know the cause of it, and until they do know the cause of pernicious anemia, and of chlorosis, they should look upon them as distinct entities, as the essential anemias, so-called. If physicians looked upon chlorosis and the secondary anemias as practically one and the same thing, the profession would be in great danger of making serious mistakes in diagnosis—at least, so far as the welfare of patients is concerned. He hesitates to make a diagnosis of chlorosis until he has excluded tuberculosis, and on his history sheets not infrequently there is written "Chlorosis," with a note, which reads: "Look out for tuberculosis." And whenever he has a patient with what he calls chlorosis, and has given to her iron in considerable quantity, and fails to see a primary response to the iron, he begins to think there is a mistake in diagnosis; just in the same way that when a diagnosis of late syphilis is made, and the iodid of potassium does not produce immediate response, he fears, perhaps, it is not syphilis; or when a diagnosis of malaria is made and quinin does not promptly relieve the fever, and that then, perhaps, some mistake in diagnosis was made.

Dr. Charles S. Bacon alluded to the habit of tight lacing among young girls during puberty or early adolescence, as a possible causal factor of chlorosis. Tight lacing, he thinks, interferes with respiration and with digestion, and by interfering with digestion it also interferes with the intestinal functions. As tight lacing had some influence in causing constipation, so it will have a bearing on the production of autointoxication, to which several observers have directed attention as being a probable important causal factor. In the hydrotherapeutics of chlorosis the impairment of respiration demands the removal or abandonment of tight lacing.

NEW YORK COUNTY MEDICAL ASSOCIATION.

Meeting held January 21.

Parker Syms, M. D., president.

Pathologic Condition of Houston's Valves.

Dr. James P. Tuttle, in presenting a specimen of this condition, stated that although seventy years had elapsed since Houston had first described these valves in the rectum there were some at the present day, notably Matthews, who even disputed their existence. The specimen, which had been taken from a man of 45, settled conclusively the question of their existence, and showed them in this instance to be markedly hypertrophied. The rectum was almost occluded by two folds of mucous membrane. It was supposed that they afforded additional support to the column of feces, and he is disposed to believe that in some cases at least they may be responsible for the occurrence of obstipation.

Lupus Treated with Galvanocautery.

Dr. W. S. Gottheil exhibited a young woman in whom a lupus of the face had been converted into nearly normal skin by the use of the galvanocautery.

Lupus Vulgaris Treated by Static Electricity and the X-Ray.

Dr. A. C. Geyser read a paper on this topic, and exhibited two patients. One of these, a young woman, had been treated unsuccessfully for considerable periods of time, at almost every dispensary in the city. The other was a man on one side of whose face the *x*-ray had been used, and on the other the static spray. The former was free from hair and smooth. The author said that many methods of treatment had been devised, but none had so nearly approached being a specific treatment as the Roentgen ray. His method consisted in placing between the patient and the *x*-ray tube a screen of lead, with a perforation opposite the diseased area. A "soft" tube should be employed, and daily exposures given at first. The worst case that he had treated by this method, one of nine years' duration, had required forty treatments, but others only eight or ten applications.

Dr. W. S. Gottheil said that some of those present had seen this woman's condition prior to this treatment, and did not hesitate to say that the result was very remarkable. It was certainly new to him, and while elaborate apparatus was required, it should certainly prove very useful for the more obstinate cases.

Exophthalmic Goiter of Syphilitic Origin.

Dr. R. Abrams reported three cases, giving a direct and undoubted history of syphilitic infection, and improving with significant rapidity under appropriate syphilitic treatment. The first had come under observation with an early syphilitic eruption. This had been dissipated by mercurial inunctions, and she had then been lost sight of for six months. On returning, there were mucous patches in the mouth, and a noticeable exophthalmic goiter, associated with dyspnea, tachycardia and great nervousness. This complication had not been benefited by the use of the ordinary remedies for this disorder, but on giving large doses of the iodid of sodium for the relief of nocturnal headache, the exophthalmic goiter had disappeared. The other two cases were quite similar.

Dr. C. W. Allen said that syphilis had often been mentioned as a predisposing cause of exophthalmic goiter, but it was new to ascribe to it such a prominent rôle in the etiology. Iodin and mercury have long been known to be of service in exophthalmic goiter, even when applied externally, yet he has never heard of any postmortem findings in this class of cases pointing to syphilis as a cause.

Dr. W. M. Leszynsky said that in a rather large experience he had not seen a single case of exophthalmic goiter which had seemed to him to have been caused by syphilis, though it was not improbable that the mental depression associated with syphilitic infection might act as a predisposing cause. The so-called therapeutic test should not be interpreted too rigidly, for it is well known that many non-syphilitic inflammatory exudates are dissipated by the use of iodid or mercury.

Cystoscopy in the Female by an Improved Method, with Demonstration on the Cadaver.

Dr. William R. Pryor read a paper on this subject and gave a demonstration of the method. His cystoscope consists of a main tube for inspection and a tube at the side for illumination. The latter extends beyond the inspection tube so that no rays can enter that one. It is important to remember that if the patient assumes the knee-chest position, as in Kelly's method, the very part of the bladder which it is most important to examine will be hidden from view unless certain special devices are used. To obviate this difficulty he recommended that the patient be placed in the lithotomy position and then the head of the table lowered to an angle of about 45 degrees. The refraction which the rays of light must necessarily undergo when the examination is made through water makes this method undesirable, and for other reasons it is apt to introduce other sources of error. With the patient in the position mentioned, on admitting air to the bladder, the latter assumes the shape of an equilateral triangle, and readily exposes to view even the pubic and peritoneal surfaces.

Dr. F. Tilden Brown said that the instrument presented was worthy of high praise, and most useful for purposes of class demonstration, as well as for the simultaneous collection of separate specimens of urine from the two ureters. He insisted that the results of such an examination and analysis are far more exact if the two specimens are collected simultaneously. For this purpose he preferred to use a double-barreled instrument.

Dr. Pryor said that with the double-barreled instrument if tubercle bacilli are found in both specimens it is no proof that both kidneys are tuberculous, and Harris's method is an absolute failure.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Meeting held Jan. 9.

President, Dr. J. H. Musser, in the chair.

Gunshot Wound of the Head.

Dr. W. L. Rodman presented a patient who had been wounded in the Philippines. He was 24 years of age and had, in October, 1899, received a gunshot wound in the parietal region, and point of exit was found in the upper part of the occipital. The patient had been under the impression that the wound was produced by a Mauser bullet, and stated that after the injury he became dazed, while afterward unconsciousness came on. The wound being on the left side of the head, there was slight paralysis on the right side. The man suffers from intense headache, and at times appears to be in a state of non compos. Skiagraphs have been taken, showing a foreign body imbedded in the brain substance, and located several inches from the point of entrance of the wound. The question to decide is whether to operate or not.

Dr. L. Webster Fox had made an examination of the eyeground of the man and found the veins and arteries normal. He believed, however, that an operation would prove beneficial.

Dr. F. Savary Pearce read a few notes of the case. The optic center had doubtless been injured to a certain degree, as had the internal capsule. He believed that an operation was indicated. Skiagraphs were then exhibited demonstrating the location of the foreign body.

Hemoglobinuria Complicating Typhoid Fever.

Drs. J. H. Musser and A. O. J. Kelly read a paper on this subject. The latter referred to the literature on the subject, and spoke of the infrequency of this complication. Many modern text-books do not mention it at all. Curschmann had seen two such cases, and Osler had reported one. The patient was a colored man, aged 23 years. The family history had been negative. On Aug. 27, 1900, he had complained of headache, anorexia and, later, fever set in. A typical attack of typhoid became manifest, with rose spots, diarrhea, etc. The Widal reaction had been positive, and tub baths had been used to control the fever. After a few days' treatment hemoglobinuria came on and lasted six or seven days.

Perforation and Perforative Peritonitis in Typhoid Fever.

Dr. William Osler, by invitation, read a paper on this topic, pointing out that until a comparatively recent date, when perforation in typhoid fever occurred, the physician could only fold his arms and await the inevitable consequence. But through the efforts of Leyden, of Germany, and J. C. Wilson, in this country, a change in opinion is apparent, and we can congratulate ourselves that the mortality in typhoid is lower than it was a quarter of a century ago. It is not the complications, such as hemorrhage and perforation, which produce death in the majority of cases, but it is the fatal toxemia. He had found that of 63 cases of typhoid treated at the Johns Hopkins Hospital during a certain period, only one-third had died of perforation. This same rate had not diminished by continuous observation, but there had been a reduction in the number of deaths from toxemia. Accidents of the former character may be divided into two stages: 1, the perforation, and 2, the peritonitis. The indications in such cases are to operate within the first twelve hours after a perforation has occurred. The speaker then detailed the history of 3 cases of typhoid, in order to demonstrate the symptoms and clinical signs of a perforation of the intestine.

In the best equipped hospitals a typhoid patient should not be left in the care of a resident physician, but a skilled man should be constantly in charge. He had drawn up a series of instructions to guide the residents at the Johns Hopkins Hospital: 1. Notify the house physician at once of any marked change in the patient's condition, or any evidences of collapse. 2. The house physician should note the onset of this change, whether intense pain, and whether relieved by ordinary measures, or whether it increased in severity. 3. The state of the abdomen, whether flat or scaphoid, or distended, the character of the respiration, sweating, muscular rigidity; the percussion note, and area of liver dulness. Auscultatory percussion may be of advantage. Examination should be made every three hours. 4. Whether there had been any change in the facial expression, or sudden drop in the temperature with sweating and acute pain. 5. A study of the leucocytes—whether increasing. The speaker stated that in some cases he had noted an increase, but not in all. The red cells should be counted and the hemoglobin estimated. A diminution of the last two might denote impending hemorrhage.

Comparing the results obtained in the treatment of cases of typhoid fever as observed in the war in South Africa, and in the Spanish-American War, it should be noted that in the former instance the mortality had reached 20 per cent., while in the latter it was 7.6 per cent. The speaker believed that the statistics furnished by the physicians composing the army board was the greatest indictment against the diagnostic ability of the members of the profession yet presented.

Of a large number of cases of typhoid operated on for perforation of the bowel, 42.5 per cent had recovered. At the Johns Hopkins, of 16 so treated, 6 recovered, and the speaker believed that when this complication was promptly recognized and treated we would have a means of saving 50 per cent. of the patients.

Dr. Mordecai Price, in discussing the paper, detailed a history of several cases of typhoid which he believed might have recovered had an operation been done. He was under the impression that it was best to operate in all cases of perforation.

Dr. Ernest Laplace thought that the lesson to be drawn was clear—the surgeon should stand in close relation to the physician in the treatment of typhoid. This relation might be the same as that in the treatment of appendicitis.

Dr. James Tyson believes that the main point in this condition was the difficulty of diagnosis. He detailed a case in which there had been sudden abdominal pain, great tympany and other evidences of perforation which had subsided within a short period, and he believes there had not been a perforation. Another important point in the treatment of this condition was the area of the bowel involved. He had also observed, in one instance, pain referred to the end of the penis, referred to by Dr. Osler.

Dr. Joseph Price was glad that a paper of this kind had been read by a physician and not by a surgeon. He had a series of 22 cases, with 10 recoveries. As to resection of the bowel in cases of typhoid, he believes that most die. He believes in an open wound and drainage in these cases.

Dr. G. G. Davis referred to the difficulty in finding a perforation during an operation for this condition. In one instance he had operated on a patient with typhoid under the impression that there was a perforation, but none could be found. In this instance he observed that the patient made an uneventful recovery and stood the operation well. Simple flushing out of the abdominal cavity seems to do good.

Dr. M. H. Fussell referred to a case in which there had been obliteration of the liver dulness. Four hours later all symptoms had disappeared. He did not know what the real condition was.

Dr. W. L. Rodman thought that if an operation was done at all it should be done early. He referred, however, to the reports of Treves and Sir William MacCormac, who had frequently detailed instances in which soldiers had been shot through the bowel, and in whom no operation had been done, and yet recovery had taken place.

Dr. Osler, in closing, stated that he could not recall one instance in his experience in which there had been a recovery from typhoid when a perforation existed. The first fifteen or twenty hours is the most important to the patient. In these cases, what if one should make a mistake when we have a means at hand which if employed might restore to health 50 per cent. of the patients?

AMERICAN.

1. **Inguinal Hernia.**—Phelps reviews the methods and history of the operative treatment of hernia and describes his own method of using the silver-wire mattress. He contrasts the Bassini and Halsted operations, pointing out their distinctive features, and claims as original in his own operation the reproduction of large masses of inflammatory material to restore the abdominal wall and the introduction of fine silver-wire filigree through the entire inguinal canal, over the transversalis fascia, adding to the strength of the weakened parts, and preventing stretching of the new material. The cutting off the hernial sac and retreating from the operation exactly as from an abdominal operation, and stitching of the peritoneum and transversalis fascia with a continued suture of fine silver wire, and also the use of fine silver wire with continued suture are claimed as original. He sterilizes this by thorough boiling and steaming, and by putting it in pure carbolic acid a few minutes before operation, after which he dips it into alcohol, holds it over an alcohol flame and thus thoroughly sterilizes it. Drainage should be avoided if possible.

3. **Drainage of Lachrymal Sac.**—The operation described is devised for the free drainage of the lachrymal sac, relieving epiphora and obviating any danger of abscess in one operation. Probing, Pond finds, has been unsatisfactory. The operation is very simple; a long silver probe, with one end blunt and the other with an eyelet large enough to carry a coarse silk string, is threaded and passed through the canal into the nose, where the end is seized with a pair of forceps and drawn out through the nostrils. The probe is then unthreaded and the string left in position with the ends tied together. The string is worn about one week, being drawn through the nose two or three times a day. In tying he makes quite a knot which, when pulled through the canal, makes an opening. He has used this operation for the past four years with good results. The canaliculus may be slit or not as deemed advisable. Most of the operations have been under cocain, but in some he has used ether. There is no pain after the first operation and the string can be drawn without causing any harm. In abscess of the sac the string gives good drainage. Three cases are reported which were severe and of long duration, but were promptly and permanently relieved.

6. **Infantile Scurvy.**—Crozer Griffith reports sixteen cases of infantile scurvy in which the symptoms illustrate the likeness which the title of his article indicates. In all the cases it was evident that a dietetic fault was at work, but just which one was not always clear. He believes that the use of commercial infant foods may have causal relation to the condition in children, and there are cases on record in which sterilized milk seemed to be the cause. He thinks this, however, is overrated; still it is to be considered. The earliest symptom is usually pain in the legs, and disorders of the gums naturally can not be found in children who have no teeth. They may occasionally have scurvy without pain, and failure to make the diagnosis is not to be regarded as a reproach to any physician. The treatment of the disease is simple. The use of fresh fruit juice has worked almost miraculous cures.

7. **Whey Cream.**—White and Ladd summarize the results of their studies on the effect of whey-cream modifications in infant feeding as follows: By the use of whey as a diluent of cream of various strengths they are able to modify the proportion of caseinogen and whey proteids of the cow's milk closely to the proportion of human milk. The best temperature for destroying the rennet enzymes is 65.5 C. Whey or whey mixtures should not be heated above 69.3 C. to avoid coagulation of the whey proteids. The percentage of whey proteids obtained by them was 1 per cent., while in the analysis of the whole milk, approximately three-fourths of the total proteid was caseinogen and one-fourth whey proteid. On the basis of this analysis they were able to obtain whey-cream mixture with a maximum of .9 per cent. and a minimum of .25 per cent. of whey proteid with percentages of caseinogen varying from .25 to 1 per cent., fats from 1 to 4 per cent., milk-sugar from 4 to 7 per cent. The emulsions of fat in whey, barley-water, gravity cream, and centrifugal cream mixtures were the same, both in their macroscopic and microscopic appearances. The combination of heat and transportation which may act together in hot weather, partly destroys the emulsion in all forms of modified milk, but this can be prevented by keeping the mi[illegible] cool during delivery. Whey-cream mixtures yield a much finer, less bulky and more digestible coagulum than plain modified mixture with the same total proteids; the coagulum is equalled in fineness only by that of barley-water mixtures. The coagulum from gravity cream mixture and centrifugal cream mixtures is the same in character.

8. **Proper Methods of Handling Milk.**—Palmer describes the methods in the Gurler farm, at De Kalb, Ill., the results of which seem to be very successful.

9. **Milk Modification.**—Whitridge pleads for instruction, in medical schools, on the methods of modification of milk for prescription feeding. He thinks that especially in the South there is a deficiency in this respect, but more or less in all parts of the country.

11. **Urgent Conditions in the Newborn.**—The conditions mentioned by Wolfe are those of premature births, plural births, pressure on the umbilical cord, on the head, and on the thorax, and toxic states of the fetal blood incident to parturition, as well as certain conditions which seem to be inherent in the germ. He gives directions as to reviving asphyxiated infants, maintaining that the method first adopted should be carried out as far as possible uniformly and the after-treatment of the child be given careful attention. He advises clean lard inunctions over the whole body, afterward rubbed off in the first cleansing of the child, and in the case of a weakened child we should always have enough absorbent cotton on hand to make a cotton envelope for the infant. He calls attention to the necessity of sometimes using stimulants, of which he advocates atropia or nitroglycerin made up from the ordinary hypodermic tablets, a teaspoonful of the solution containing from 1/2000 to 1/3000 of a grain of atropin, while the trinitrin solution should contain a similar fraction of a drop of the 10 per cent. solution. A dose of either may be given and the effects watched, and ordinarily repeated from two to six times in twenty-four hours as a stimulant to circulation and respiration.

12.—See abstract in The Journal, xxxv, p 51.

13. **Mastoid Disease.**—Oppenheimer reviews the symptoms and authorities in mastoid disease and its more serious complications.

14. **Ear Disease in General Medicine.**—The relation of ear disease to various disorders, mumps, influenza, nasal and nasopharyngeal affections, lung disorders, diseases of the alimentary tract, typhoid fever, syphilis, rheumatism, neuritis, cardiac disorders, kidney disease, gastro-intestinal diseases, eye diseases and drugs are all noted

15. **Colic.**—This disorder is an irregular peristalsis of the small intestines, a contraction of the various muscular coats of the intestinal tract accomplished with such violence that the nerve filaments are unduly compressed and pain produced. The causes of infantile colic are enumerated: 1. Flatulence, which may be due to some congenital deformity of the child itself, in its defective development, etc., or it may be the fault of the mother either in her diet or attention to the bowels. Drugs, emotional disorders, etc., on the part of the mother, may have their effect, and it may be due to overfeeding or to improper quality of the food, and sometimes underfeeding may be the cause of colic. Refrigeration, leaving the child lie too long in a wet condition, may be the cause. Illoway does not think swallowing of air has any special effect in this way. It is possible that malarial influence may be at work. The symptoms are discussed in detail, with special reference to the cause, which is an important matter of treatment. For immediate relief the aromatics or carminatives have been employed from time immemorial, and several prescriptions are given. At first, in his early practice, he employed opium, but has found that certain simple remedies were as efficient. He has found nothing superior to milk of asafetida, which is taken readily by most infants and is innocuous. One of the principal things, however, is removal of the cause. When it lies in the infant there is not much to be done except to relieve as far as possible the pain and give attention to the bowels. The diet in the mother and child should be given careful attention.

16. **Speech and Its Defects.**—Makuen discusses the defects of speech due to various causes, to defective hearing and to defective psychic apparatus. In the development of the child attention should be given to this last point, and babbling and prattling should be encouraged in a quiet way. Early examination of the organs of speech should be made whenever there is any sign of defects, and hypertrophied tonsils and all irregularities be looked after. Stammering is not due to arrest of development, but to certain defects of the nervous system. He describes his plan of treatment in these cases. The approximate cause of stammering is a functional derangement of the nervous mechanism of speech causing an incoordinated action of the hitherto automatic peripheral apparatus. There is only one rational way and scientific method of producing normal action, that is physiologic exercise, the patient conscientiously endeavoring to gain control over the entire muscular system with especial attention to those parts immediately concerned with the processes of speech. Some ingenuity may be necessary sometimes to determine just what particular exercise is best suited to each individual case, and great care and perseverence may be needed.

17. **Summer Colds.**—Flick gives his experience and that of his family with summer colds, which he attributes to the use of a swimming bath. There is very little doubt in his mind that the infection was conveyed in this way, directly through the water. He regrets that he was unable to give a bacteriologic study, but at the time his attention was called to the facts and the material was available he had not the opportunity.

18. **Lateral Ventricles.**—Spitzka gives diagrams, taken from life, of the position of the ventricles, with special reference to the surgical procedure of tapping, which he assumes has a future. The diagrams are very instructive. He calls attention to the sources of uncertainty that will have to be taken into account, such as variability in relation to portions of the brain, that is, of the external surfaces of the cranium. The condition differs in different individuals. For the purpose of effecting an entrance into the cavity of the ventricles, the safest road would seem to be the one which is directed into the trigonum, the roomiest part of the ventricle and the least variable. The article is most intelligible in connection with the illustrations.

20. **Milk Sterilization.**—The effects of heat on the bacterial flora of milk are described by Blackader, who sums up his results by saying that milk, in sterilization by heat, is altered to an extent varying according to the elevation and duration of the temperature used. The proteids are modified and rendered apparently less digestible, though our knowledge is yet imperfect in this regard. The combination of saline ingredients is probably more or less broken and the salts assume conditions in which they are less readily absorbed. The natural ferments, whose presence in milk it may be inferred is to assist digestion in the infant's stomach, are destroyed. An alteration takes place in the emulsion, which may also have a distinct effect in lessening the digestibility of cow's milk by the infant. He also points out that it is very important that the milk, after sterilization, must be kept at a low temperature, and this, used for many days, is not free from danger. He therefore thinks it very desirable in infant feeding, to use fresh milk drawn with careful precautions against contamination, and in which the lactic-acid-producing bacteria are present in such small numbers as to induce no important alteration. Such milk had better not be sterilized, but since we can not always obtain it, the lesser of two evils is to have the milk sterilized at the lowest efficient temperature, viz., 60 C. maintained for fifteen minutes.

21. **Gall-Stones.**—Ricketts protests against dependence upon the internal use of drugs and methods of poulticing in cases of pus formations, and favors cholecystotomy with drainage. The latter, through the abdomen and gall-bladder, must be maintained until we are confident that no stones remain in any biliary space that can be explored by a probe. He thoroughly washes out the bladder after removal of the calculi, and frequently finds others brought away. He thinks that if cholecystotomy is the primary operation for removal of the gall-stones, the few cases in which there may be recurrence can be dealt with more successfully by a secondary cholecystotomy if need be, than by any one of the other procedures named for their primary removal. As regards surgical intervention, he objects to two tempo operations, which he thinks are to be condemned.

22. **Appendicitis in Females.**—McRae reports several cases of appendicitis in women, and thinks that the disease is frequently overlooked in the female. Diagnosis is much more difficult. It usually occurs at or about the menstrual time, and is often attributed to genital troubles. The pain of appendicitis, he says, is more sudden in its onset and more acute than that of pelvic disease. It is frequently combined with nausea and vomiting. Muscular spasm is marked; while practically absent in pelvic disease, disturbance is very much greater and progress more rapid. An intact hymen argues strongly for appendicitis. When in doubt and the symptoms are aggressive it is safer to make a diagnosis of appendicitis and operate than to delay until the case is hopeless.

23. **Adenoids.**—The conclusions of Kerrison's article are that pharyngeal adenoids are much more common than generally supposed in children; that cases of moderate development are often not recognized; that growths of moderate size, though not necessarily accompanied by marked symptoms at the time of their development, are often responsible for grave conditions during adolescence or in adult life; that unless removed, in nearly all cases they are accompanied by more or less impairment of hearing; that the presence of adenoids does not greatly add to the gravity of the intercurrent disease and makes the patient more susceptible to tubercular and diphtheric infection; that the *periodic examination in children* for this should become a routine measure; that moderate cases, no less than the extreme ones, demand surgical treatment; that the treatment should aim at complete ablation and removal of the growth and is best done under general anesthesia.

24. **Fatty Degeneration of the Heart.**—According to Satterthwaite, this is a common affection, though it is not to be classed as a disease *sui generis*, but rather as a metamorphosis or process attending on loss of compensation and valvular disease and nearly as often in non-valvular. It is caused by fevers, toxemias, dyscrasias, disorders of nutrition, and mechanical injuries. It may also be a physiologic process, as in senility or after parturition. For practical purposes he divides it into three stages: 1. Early, in which the prognosis is best for a complete recovery. 2. Intermediate, in which the arrest of fatty processes *in toto* is hardly probable, but the affection may be so improved that the patient need not be seriously disabled. In this we may have a physiologic if not a pathologic cure. 3. In the final stage, marked by such profound implication of internal viscera that their functions are in abeyance, the prognosis is always bad and the end will hardly be delayed beyond a few months.

26. **Galveston Storm.**—West gives his experiences and observations in connection with the recent Galveston storm, and notices the unsanitary conditions of overcrowding and filth and general impairment of sanitation that followed the disaster, together with the excessive high temperature, increase of disease-bearing insects and temporary failure of the water-supply. There seems to have been an increase of malaria in the place since the storm, and gastro-intestinal catarrh and dysentery were prevalent for a while. Typhoid fever also made its appearance and scarlet fever, diphtheria, epidemic influenza and dengue occurred, though thus far not epidemic. Many cases of mixed infection were noted. The city is still far from a sanitary condition, as there is no proper system of sewage.

28. **Heart Disease.**—Heffron thinks the treatment of the later stages of heart disease should be guided: 1. By the condition of the heart, that is, when compensation fails, it should be relieved of all extra work, and absolute rest in bed is what he recommends for this purpose. 2. The volume of the blood should be diminished as much as possible, and mainly by the use of such hydragogue cathartics as least disturb the general conditions. The remedies he advocates, in order of their importance, are elaterium, calomel and salines, but at the same time the diminution of ingested fluids must be insisted on. 3. The nervousness of the patient which increases the work of the heart must be controlled. For this he recommends ice-bags for temporary relief, but medicines that act upon the nerve centers have to be relied upon. The alkaloids of opium, codein and morphin are first, and he thinks heroin is a fraud. In some cases where the nervousness is not extreme, he has good results from the use of the abstract of cannabis indica made by the late Dr. William Manlius Smith, which is uniform and efficacious. He uses this first as a rule, often adding the others. The next point is the diet, which must be managed so as to be nutritious, not very bulky, and easily digested. When dropsy comes on he recommends hot-air cabinet baths together with a purgative. The use of cardiac stimulants is also noticed as affecting the muscles of the heart, and also the Schott treatment, and general exercises under the direction of a physician. If compensation can be restored, as it often can, the patient should still be kept under observation and avoid excessive demands on his powers.

32. **Inspection of the Rectum.**—Johnstone describes the instruments, protoscope and anoscope, used in examining the rectum, and the technique of their employment, also a table specially adapted for this purpose. He considers, in conclusion, Houston's valves, noticing particularly Mathews' opinion that they do not exist. He is as certain that they do exist as that the soft palate does, though whether they should be called valves he does not venture to say. In fact, he thinks they are comparable to the soft palate to some extent in efficiency and function.

33. **Some Medical Questions.**—Under the heading, "Some Theories for Which I Should Like to See the Profession Try," Owen notices the lay management of hospitals, which he thinks should give way to medical administration, the discipline of irregular and non-ethical practitioners, etc. He does not think, however, that a physician should be prevented from patenting a valuable medicine or appliance. The principal point is that the physicians should try to obtain control of hospitals and all their details, also of boards of health, and should insist that all men who are allowed to practice medicine should at least be qualified by education. He thinks there should be a branch of the judiciary whose sole function should be the control of public health matters, and all practitioners of medicine should be within that court's jurisdiction.

52. **Brush Massage.**—Fry recommends the use of a dry bristle brush for the purpose of massaging, and claims it has many advantages over the ordinary methods. It is easily learned and can be taught to the ordinary nurse. As he employs it, it consists in kneading all exposed portions of the body with the brush, keeping it in contact with the skin and manipulating with a circumductory and creeping movement with varying rapidity and pressure. The dry brush adheres to the skin, bringing with it the superficial structures in a way that can hardly be described, but can be appreciated on trial. Specially constructed brushes are not necessary. From a good assortment of flesh brushes, one can always select a suitable one for the purpose. He claims that it has an excellent effect on tics, tabes, neuralgia, neurasthenia, hysteric and neurasthenic aches and pains, especially on the neck and back paresthesias.

54. **Uterine Arteriosclerosis.**—This condition has not been much mentioned in English literature though its existence is not questioned. Findley reports several cases and discusses the literature of the subject. He thinks that the finding of arteriosclerosis in the uterine arteries is what should be expected in advanced life and it is not surprising that the clinical picture, pain in the hypogastrium, uterine hemorrhage, anemia and impairment in a woman 70 years of age should be mistaken for carcinoma of the uterus. He thinks that while it must be proven that it is responsible for uncontrollable uterine hemorrhage, there are many cases in which it is overlooked, as in senility; hemorrhagic metritis of the menopause may be in reality hemorrhagic infarction of the uterus based on arteriosclerosis and calcareous degeneration of the uterine vessels. So long as the condition does not rest upon a toxic basis, but rather on senile conditions, the control of the hemorrhage is all that we can expect. If the patient is dependent upon her labor for a livelihood, and the hemorrhages are taking her strength, then vaginal hysterectomy will be indicated. If it is possible for the patient to refrain from

work during hemorrhage, Findley advises rest and the use of ergot, styptics and tamponing. If, however, this is ineffective and the patient's general condition demands it, vaginal hysterectomy must be resorted to.

56.—See abstract in The Journal of January 12, p. 128.

63. **Gastroenterostomy.**—Meriwether discusses the use of the Murphy button in malignant strictures of the pylorus; even in benign strictures the trend of opinion is growing more and more favorable to the use of the button. The saving of time it offers is valuable, and since in suture operations the statistics give the same mortality the button operation should be preferred. The suture operations have usually been performed in selected cases, while the button cases have frequently been in very bad shape. The technique is given in detail. The author advises that the longer half of the button should be used in the stomach; possibly this is not in accordance with others' experience. He advises gastroenterostomy in all cases of malignant disease of the pylorus when the ordinary operation can not be done, even if the patient is weakened and the case far advanced; the Murphy button is to be used in preference to sutures as being equally as good in results and requiring much less time.

64. **Anteflexion.**—Among the causes of anteflexion aside from corsets, overstudy during the period of puberty and other things, Kingman suggests that excessive dancing and bicycle riding are important factors in many cases. The operation he seems to favor is the Dudley, which he has come to use of late with increasing frequency and great satisfaction. He also insists on the importance of cutting the posterior ligaments, which he thinks is a distinct step in advance.

65. **Appendicitis.**—After reporting a series of cases, Currier remarks that two classes in which he would think it wise to avoid surgery are: 1. Those who promise with great certainty to get well, provided they can be watched and operation performed later is necessary. 2. Those in which there is absolutely no hope. In all others operation is advisable. He does not think it well to give up drainage and irrigation where there has been much suppuration nor gauze packing in cases where hemorrhage is likely to occur, though he admits that it may do much damage in its adhesion to tissue. He is firmly convinced that it is good routine practice to open the bowels with calomel twenty-four hours after operation, unless shock is still continuous.

67. **Drum Perforation.**—Spear's article is a protest against the ordinary idea held by many, even in the profession, that perforation or rupture of the drum is necessarily serious in its consequences to hearing, etc. In certain diseases of the middle ear the intact drum is a positive hindrance to cure. While under ordinary circumstances it serves a useful purpose of protection and tends to perfect reproduction of all sounds, in some cases excellent hearing can be secured without it, and in others it is itself a hindrance to hearing, yet perforations or ruptures in it can be made with indifference and its tendency to heal is emphasized.

72. **Middle Ear Tuberculosis.**—The special features of middle ear tuberculosis, according to Bruck, are absence of pain, slight reaction on surrounding parts and its tendency to cause in a short time excessive destruction in the most cases. There are, however, cases where the progress is slower, suppuration diminished, and even spontaneous cure may take place. In some instances the cases simulate an acute purulent otitis media, but in middle ear suppuration no tubercular patient is to be considered as tubercular with absolute certainty until the bacillus can be demonstrated. The prognosis is nearly always bad; complete healing is rare. The general condition of the patient must be looked after and careful local treatment given to the ear. Boiled water douches one to two times daily, followed by loose tamponing with sterilized gauze, are advised. In cases of fetid suppuration, Bruck uses formalin solution, 4 to 6 drops to the quart of luke-warm boiled water. Where the defect in the drum membrane is great, the powder treatment may be employed, the powder containing europhen and boric acid, applied after first syringing and wiping the ear carefully, softening tough masses of secretion with carbo-glycerin, etc. For small granulations absolute alcohol diluted with water, using gradually less until pure alcohol can be used. Larger granulations should be cauterized. Surgical treatment should largely depend on the patient's general condition.

74. **Iodol in Treatment of Tuberculosis.**—Tyson has been using inunctions of iodol for the last two years in cases of consumption, with marked improvement in the symptoms. This was only temporary in advanced cases, though in incipient ones it continued as long as they were under observation. The cough and expectoration sometimes disappeared entirely, or in every case diminished gradually, and the abnormal breathing signs became decidedly diminished in intensity. The weight was increased, expectoration decreased, strength and appetite improved. In addition to the iodol inunctions, the patient received 1/25 gr. of strychnia three times a day, with good nourishing food and proper outdoor exercise. The inunctions contained 20 gr. to an ounce of olive-oil. The quantity rubbed in was ʒi three times daily, increased gradually to ℥ss, say about ʒi a week, and requiring about ten minutes for the patient to rub it on.

83. **Spinal Cocainization.**—Kammerer gives his experience with spinal cocainization, in all 39 cases. Among these there were 10 unsatisfactory results, 6 in which it was impossible to obtain the cerebral fluid by puncture and 4 in which analgesia failed to appear. As regards the causes of failure in the 6 cases, there is no explanation. It is hardly possible that the needle was misdirected; there may have been some peculiar condition existing. As regards dosage, he uses, on an average, 10 or 11 drops of a 2 per cent. solution of cocain, sometimes exceeding this a little. He has seen anesthesia come late, even after thirty or forty minutes, and yet be very complete. In 4 of his cases there was more or less pronounced analgesia of the upper extremities, and in 1 it extended so far over the whole body that the lips, forehead and scalp could be pricked without pain. The patient was a strong, powerful man of 30, and only ¼ grain of cocain was employed. In the great majority, however, analgesia only extended to the ensiform process, and there were no unpleasant by-effects, excepting in a few instances. He concludes that they are more pronounced where the anesthesia is most perfect. They were not observed in the 4 where the analgesia failed. In 2 gastroenterostomies there was a certain amount of discomfort complained of on tension of the abdominal wall and manipulation of the stomach and bowel; in others there was more or less sensibility remaining. He thinks that at present we can only use the method in operations on the lower extremities and the pelvis; the higher we operate the more likely we are to have unpleasant accompaniments and defective analgesia.

85. **Aspirin.**—Toepfer has employed aspirin for its analgesic effects in acute rheumatism and other rheumatic disturbances, measles, malaria, intestinal colic, ovarialgia and other neuralgias, hemicrania, lumbago, sciatica, spinal irritation, arthritis deformans and uterine carcinoma. He finds it more or less effective in these conditions and quite satisfactory in some. It should not be employed with alkalis, like carbonate of soda. It is insoluble and must be given as a dry powder or shaken up in a cold watery mixture with neutral reaction. It is usually only a palliative. Only very rarely did he find any unpleasant effects, such as tinnitus, vertigo and headache, from its use.

87. **Rheumatic Fever in Throat Affections.**—According to Thomson and other authorities, there is a general acceptance of the view that there is an undoubted association between rheumatism and the tonsil, which is expressed from two points of view. One is that the rheumatic poison enters the system through the tonsil, the inflammation of which is the first sign of disease. The other is that tonsillitis in certain cases is one of the manifestations of the rheumatic diathesis. Both of these views are supported by observation. He thinks the various theories that have been propounded are somewhat premature. It is safer to await further pathologic investigation. We also want to know more about rheumatism itself and the

various causes and forms of tonsillitis associated with it. Thus far peritonsillar abscess or quinsy is one form which is not accepted as being rheumatic. The present state of our knowledge in relation to tonsillar affections may be summarized as follows: 1. Undoubtedly a certain number of cases of rheumatism are preceded by angina, a proportion varying from 30 to 80 per cent. Both rheumatism and angina have many etiologic points in common, seasons of wet, cold, fatigue, depression, vitiated air, etc. The connection of angina and rheumatism, though undoubted, is not yet clearly established. The tonsil may be the point of entrance of the rheumatic virus, though showing no indications of being affected. The particular affection of the throat associated with rheumatism is not clear. Peritonsillar inflammation does not seem to be arrested by antirheumatic remedies. Many cases, however, of parenchymatous and lacunar tonsillitis are considerably benefited by salicin and salicylate of soda. It does not follow that this proves the rheumatic nature of the disease. The question requires further research in two directions: 1. In differentiating the various forms of angina and settling the one which is connected with rheumatism. 2. In discovering the true nature of rheumatism itself. The relations of the pharynx and larnyx to rheumatism are also noticed.

88. **Spongyfying of Labyrinth.**—Holinger attempts to show that this condition, associated with gradually "progressive deafness," forms a clinical picture which he thinks is best impressed by the name given above. The diagnosis can be made in the living in a comparatively early stage, from history and the trio of functional tests: 1. Short or negative Rinné. 2. Increase in hearing of low sounds (A) by bone conduction. 3. A large part, one to seven octaves, of the lowest sounds can not be heard by air conduction. 4. The prognosis as to life is good: as to recovery of hearing bad. 5. The treatment must be very judicious. We can judge and compare of its effects in a given disease only when we are able to make an absolute diagnosis. The patients who have been treated from the start are often in a worse condition after years than those who have been left alone.

92.—See abstract in The Journal, xxxv, p. 1425.

102. **Spondylolisthesis.**—This condition, consisting of a sliding of the body of one of the lower lumbar vertebræ, is noticed by Lord, who describes a case which apparently followed typhoid fever. So far as he is aware this has not been before mentioned as a cause of the condition.

103. **Obliterating Hyphema.**—This term seems to Weymann the best suited to describe the condition found in the cases here reported. It applies to contusions, copious enough to obviate all view of either of the anterior chamber or the fundus. The impossibility of intraglobular inspection, puzzling surface signs and complete loss of sight, the absolute necessity of constitutional prognosis and the uniform measures of treatment until clot-absorption, make the subject worthy of some attention. He offers the following deductions: 1. Contusion of the eyeball resulting in obliterating hyphema may, or may not, be complicated with deeper lesions, but uncomplicated cases are in the minority. 2. They are apt to be followed by glaucoma, the chief cause of the suffering. 3. In the absence of infection acute iritis is rare. 4. When the contusing force at the same time secures non-infected drainage from the anterior chamber the immediate reaction, though perhaps very severe, subsides within six to twelve hours, glaucomatous tension not being able to appear. 5. The stippling of the anterior epithelium and the parenchymatous haze are due chiefly to profound shock to the local lymph system, for clouding does not disappear with the reduction of intra ocular pressure. 6. Drawing off the effused blood is neither practicable nor desirable, for it clots in a few moments, and the fibrin binds the clots closely to the iris which tend to narrow the pupil. On the other hand it shuts off the light and serves as an iris splint, but a painless subacute iritis occurs, tending to cause synechiæ. 7. Atropia should always be instilled, not only for dilatation, but on account of its analgesic effect. 8. Glaucomatous tension should be at once relieved by passing a cataract knife into the anterior chamber parallel to the plane of the iris, making a valvular wound which may be made to drain at will. 9. For the inflammation he orders calomel, 6 gr., which has an excellent revulsive effect, and compresses as hot as can be borne, for thirty minutes out of every hour for twenty-four or forty-eight hours. 10. The prognosis should be guarded until the clot absorption is complete. 11. The commonest deeper complications are: luxation of lens, consecutive cataract, iridodialysis, fundus hemorrhage and retinal detachments.

108. **Pulmonary Hemorrhage.**—The treatment of pulmonary hemorrhage, according to Robinson, may be summarized as follows: 1. Relieve the patient's anxiety; unloosen or remove clothing, and place him in a semi-recumbent position. 2. Injection of 1/4 or 1/3 gr. of morphin with 1/120 to 1/60 of atropin. 3. A teaspoonful of common salt, dry on the tongue, or 20 to 60 minims of aromatic sulphuric acid in a small quantity of water may also be given. 4. Order an ice-bag on the chest. 5. If the above fails to check hemorrhage within a short time, cord the extremities, not too tight, but sufficiently to prevent return of venous blood. 6. Under no circumstances give ergot, alum, gallic and tannic acids or any other local astringents. These have no special effect on the lung and irritate the stomach and cause constipation. 7. Insist on absolute mental and physical rest with scanty, nutritious and chiefly a fruit diet, and relieve constipation either by Epsom salts or by enemata. 8. As a prophylaxis against further hemorrhage, have the patient consume large amounts of gelatin prepared in various forms. 9. Mild collapse can be left alone. In severe collapse administer camphor hypodermically and nitroglycerin, also strychnin, not digitalis. Apply hot water bottles to the lower extremities. 10. It sometimes becomes necessary to resort to enteroclysis and large amounts of saline solution or to give the latter subcutaneously or intravenously.

112. **Gastroptosis.**—After describing the conditions, its anatomy, symptoms, etc., Chambers says that the objects sought for in the treatment are: 1. Increase of intra-abdominal tension. 2. To correct any error of secretion or motility. He frequently commences by applying strips of adhesive plaster, which gives relief until the patient is able to obtain an abdominal bandage. This should be fitted carefully so it will press firmly upon the hypogastrium. As a rule it is not needed at night. Before applying it in the morning the intestines are forced up and the bandage laced from below upward. The strength and tone of the abdominal muscles are encouraged by massage, electricity, exercise, deep breathing, etc. The medicinal and dietetic treatment varies. In hyperacidity, acids, alcohol, fruits, etc., should be strictly prohibited. The diet should be nutritious and digestible. Liberal quantities should be given at least four times a day. In severe cases a more strict diet is necessary. The drugs which he has found most useful are those which are sedative to the stomach, and assist in the digestion of starches, correct acidity and relieve constipation. Irritating cathartics should be avoided. Mixtures of bismuth carbonate, extract of cascara sagrada, tincture of belladona and two teaspoonsful of calcined magnesia two hours after meals give good results in many cases. In some cases taka-diastase is useful. A number of cases are reported.

120. **The American Cigaret.**—Seymour maintains that the cigaret deserves its bad name even though it may not be found to contain harmful foreign substances other than tobacco. The toxins of tobacco are developed by combustion and carried directly to the mouth. The material of the cigaret is often refuse tobacco from old cigar stumps, and moistened by the maker's tongue, which may be syphilitic. He concludes that the prepared cigaret is too vile for any defense.

121. **Acute Opium Poisoning.**—Bullard prefers the stomach-tube in this condition, first washing out the stomach with boiled water and then the rectum and bladder. Hypodermic injections of salt solution, he thinks, might be rational, together with bleeding and forced artificial respiration. Atropia, though a functional antidote, must be used with great caution.

and the combination of the two poisons may not improve matters. Ether, camphor, strychnin, caffein, coffee and electricity are all used. Flagellation and rough attempts at rousing the patient are objectionable.

126.—See abstract in The Journal, xxxv, ¶39, p. 1659.

127. **Asthma.**—Dunn reports cases and discusses the etiology of this disease, maintaining the opinion that it is in most cases a reflex from irritation of the nasal mucosa due to retained products of tissue metabolism. This places asthma in the same class of disorders as gout and epilepsy, the difference in the focus of irritation causing the difference in the symptoms.

129. **Perineal Lacerations.**—Brownson finds that perineal tears are often unavoidable, but perineal support is useless and often dangerous. Pressure should be applied directly to the head when it seems to be advancing too rapidly for the safety of the perineum. Pressure on the head by the whole hand and not by the finger tips, with profound anesthesia in most cases, if assistance is at hand, and then if the head can not be delivered readily, slow, gradual and careful delivery by the forceps can be done. Such measures will save at least some of the perinea from laceration.

British Medical Journal, January 26.

Summary of Researches on the Propagation of Malaria in British Central Africa. C. W. Daniels.—Malaria prevails all through Central Africa at a height of 5000 feet near the equator, and up to at least 3200 feet at 15 degrees south latitude. It is more prevalent in some districts than in others. The estivo-autumnal is the only parasite that was found alike in Europeans, natives and Indians, with one exception, and in this case it was probably imported. The chief agent in the distribution of malaria in Central and South Africa is Anopheles funestus. Man appears to be the only intermediate host. Native children are generally infected, immunity occurring rather earlier apparently than in some other countries. The percentage of natives with enlarged spleen was decidedly marked between the ages of 2 and 4 years, while in adults this was seldom met with. As regards the prevention of malaria the author lays considerable stress on the value of drainage under proper methods. The habitual protection from mosquitoes would require irksome confinement, as the African Anopheles are less exclusively nocturnal than the Italian for example. Isolation from native settlements here may have some value, but no method is of general application to the exclusion of others. A combination of methods strictly in accordance with local conditions promises the best results. The author thinks the greatest difficulty in exterminating malaria will be to overcome the scepticism on the subject in the tropics, which he himself shared until within the last two years. We have not yet learned all the natural history of malaria-bearing mosquitoes and possibly much help may be obtained from important facts as yet unknown.

Notes on the Life History of "Anopheles Maculipennis" (Meigen). Louis W. Sambon.—This paper, with its illustrations, is a valuable contribution to the natural history of malaria, giving as it does a full account of the life history, so far as known, of Anopheles maculipennis, which the author thinks is identical with the American Anopheles quadrimaculatus and the Italian Anopheles claviger. The species is, therefore, very widely distributed; it seems to have followed man in his migrations and is usually found in connection with habitations. Observations were made on the spreading habits during a recent malarial outbreak at Ostia, in which Dr. Sambon shared. He found that it does not migrate far from its breeding ground, but is often carried by coaches and railway carriages for long distances. During strong winds this species always takes shelter in thick foliage, and there is not much danger of its thus disseminating. The water collections chosen by the Anopheles are not so likely to be dried up as those chosen by the culex, but this may happen in extreme drought. They can live, moreover, in moist ground for several days, and pupæ continue to develop perfectly well even when the mud is dried up entirely. The conditions at Ostia were not favorable for experiments with larvicides. The authors think that more may be hoped from filling up and draining or stocking with fish than from other measures.

Preliminary Note on an Unclassified Type of the West African Fever. S. D. Thompstone, R. A. Bennett and H. E. Annett.—The authors describe a new form of West African fever, generally ushered in by slight rise of temperature, followed by profuse perspiration, and a partial fall of temperature to about 99 degrees. After about a twenty-four hours' period of apyrexia the temperature again begins to rise, at first slowly, but when 105 is passed, with alarming rapidity. It may reach 107 on the second day. For fourteen or even thirty days there is absolutely no tendency for it to fall, the skin acts either very slightly or not at all and all antipyretic drugs fail. The tongue is at first furred on the dorsum and red on the edges, but later it becomes dry and shriveled. There is no enlargement of the liver and spleen. The bowels are regular or loose. The conjunctivæ are injected and pupils contracted. The mind remains reasonably clear in most cases, excepting at the highest temperature; great anxiety and restlessness are constant symptoms in the earliest stages. No plasmodia or pigmented leucocytes have been found in the blood. In two of the later cases the blood tended to coagulate the moment it was exposed to air, and satisfactory films were hard to obtain. The treatment of the condition is summed up in one word—baths. The cold bath is used until the temperature is brought down to 100 or 99 degrees. The patient usually sleeps for about an hour and then feels fairly comfortable, but the temperature usually tends to creep up, and in eighteen or twenty-four hours it is back to its old point. It was found, in one patient who recovered, that after the cold bath the temperature could be kept down by cold packs renewed at hourly intervals. If the patient is to recover, some change for the better is to be looked for at the end of the third week, the temperature falling and keeping down to a certain extent. Convalescence is gradual, and it may be six weeks after the onset before it becomes normal again. About 50 per cent. of the cases terminated fatally. In the addendum to the paper, by Dr. Annett, it is stated that examination of the blood gave nearly the normal number of red corpuscles, over 4,000,000, and there were 15,000 white, with 90 per cent. hemoglobin. No micro-organisms were cultivated. The disorder occurs during the dry season, when malaria is less prevalent. The onset, symptoms and course of the disease are atypical to malaria; no rigors or shivering, hot or cold stages, vomiting or enlarged spleen. The continued hyperpyrexia is characteristic, continuing over a long period, and then gradually declines. The resistance to drugs, absence of hemamebæ and pigmented leucocytes, the especial tendency of the blood to coagulation and its richness in red corpuscles and hemoglobin are also notable characteristics.

The Lancet, January 26.

Suggested Method of Preventing Water-Borne Enteric Fever Amongst Armies in the Field. Louis C. Parkes and Samuel Rideal.—The authors give the results of experiments for destroying the water-borne germ of enteric fever, and the remedy which they seem to find most effective is acid bisulphate of sodium, of which it was found that 1 gram will render a pint of water sterile in fifteen minutes, even if the water contains as many as 50,000 colonies of typhoid bacilli to the centimeter. They recommend the use of it in 5 gr. tabloids, put up in boxes containing about 350, enough to sterilize 100 pints of water. One of these boxes should be carried by every soldier, in his haversack, and supposing him to consume five pints a day, the box would last for three weeks. Instructions should be given by the medical officer to the rank and file, as to the use of the tabloid, especially as to the desirability of allowing it to remain for at least fifteen minutes in solution before the water is consumed. The bacillus typhosus is not by any means resistant to such acids. By this simple means the combating of infection has a future before it, especially under conditions where means of sterilizing by boiling and filtering are not readily available.

Gazette Med. Belge (Liege), January 17.

Technique of Cryoscopy. Bienfait.—About 15 c.c. of the serum or other fluid to be examined are placed in a large test-tube, which is set in a vessel containing salt and chopped ice. The temperature falls to two or three degrees below the freezing point, but the fluid does not freeze—there seems to be a sort of supersaturation by the cold. A minute piece of ice is then dropped into the fluid and at once it freezes solid. The temperature rises to .55 C., where it remains as the normal freezing-point of the serum of the blood. [Waldvogel attributes the higher freezing point for blood serum which he observed in typhoid fever, to the presence in the blood of the typhic antitoxin, mentioned in The Journal, Dec. 22, 1900, p. 1667. He consequently assumes that when the freezing-point is only slightly above normal, it demonstrates a defective production of the antitoxin and an unfavorable prognosis. Ed.]

Presse Medicale (Paris), January 9, 12 and 16.

Importance of Zymases in Infant Feeding. A. B. Marfan.—The presence of a zymase in human milk has been established, and Marfan has also found a lipase and an anaerooxydase. He believes that milk is not an inert fluid, but that it partakes of some of the properties of the tissues. It is possible that the ferments in it have a stimulating and regulating action on the nutrition until the organism has developed sufficiently to supply its own stimulating and regulating substances. Each kind of milk has probably its special ferments, and it may be a mistake to destroy them in sterilizing the milk. The aim in artificial feeding, therefore, should be to add to sterilized cow's milk the zymases peculiar to human milk.

Tests for Sugar in Children.—P. Nobecourt.—Very little information in respect to the functional activity of the intestinal mucosa can be derived from alimentary lactosuria and saccharosuria in children. Alimentary glycosuria, on the contrary, may afford considerable insight into the functional capacity of the liver and tissues. The childish organism in physiologic conditions is able to fix large amounts of glucose—as much as 5.9 gm. per kilogram in some cases.

Revue De Chirurgie (Paris), January.

Ectokelostomy for Hernia. J. Vitrac.—In operating for inguinal hernia, for instance, an incision is made in the abdominal wall above and the mobilized hernia sac is drawn up and out through this second incision. It is then trimmed close to the skin and fastened provisionally. The hernial wound is then sutured and a drain inserted in the marsupialized sac above. When this is removed in a few days the secondary wound is sutured. The chief advantages of this method are its simplicity, rapidity, freedom from danger to the viscera and the possibility of dispensing with general narcosis. The results were most satisfactory in the two cases in which Vitrac has applied it. One patient did not require even local anesthesia.

Obturator Hernia. P. Fredet.—Obturator hernia with a double sac has been noted, the external sac formed of the prevesical fascia. The hernial sac may be arrested in its downward course by a branch of the obturator nerve and may cause pain and symptoms of paralysis by traction on this nerve. These symptoms vanish as the sac emerges from the foramen and leaves the nerve behind it. In some cases the nerve offers such resistance that the hernial sac is diverted from its direct course and lodges behind the external obturator muscle.

Progres Med. (Paris), January 5, 12 and 19.

Latent Epilepsy. Ardin-Delteuil.—This article is concluded from Nos. 50 and 52. It states that the etiology, evolution and prognosis of the latent forms of epilepsy are the same as for the ordinary form, and may blend with the latter. The final dementia even seems hastened in psychic epilepsy, as the thought-cells are used up more rapidly. The prognosis is, therefore, exceptionally grave from this point of view; the mind of the patient is threatened and confinement will become necessary sooner or later. It is also grave from the point of view of society on account of misdemeanors and deeds of violence which may result. Suspicion should be aroused by any motor, sensory, vasomotor, nervous or psychic manifestations of stereotyped reproduction and photographic repetition, sudden, brief, and followed by depression, stupor and forgetfulness. In regard to the psychic phenomena, the violence, publicity, ferocity, marked readiness to take offense and cherish stubborn animosity, are distinctive characteristics. Besides investigating the personal and hereditary record, the toxicity of the urine should be determined as the urine in even the latent forms of epilepsy is usually remarkably hypotoxic in the intervals between the seizures. It should also be examined immediately after an attack, for increased urea and phosphates with a tendency to inversion of the formula. The temperature also, after the latent seizure, will show a slight elevation, with return to normal in a few hours. Mydriasis may also be observed during the seizure with myosis at the end. When latent epilepsy is determined, a medical certificate to that effect should be given the patient, which he should always carry. In regard to the criminal responsibility, the subject is absolutely irresponsible during a seizure, whatever its character and the amnesia, and comparatively irresponsible just before and just after one, according as the pre-epileptic and post-epileptic stage are more or less pathologic. In the intervals there is complete responsibility if the mental faculties are still sound; attenuated if the subject exhibits tokens of the epileptic character. If the mental faculties are affected, the irresponsibility is complete. The degree of responsibility should not be determined from the apparent preservation of the conscience during the psychic paroxysm. Still less is it possible to accept as a criterion of the retention of conscience, the more or less complete retention of memory.

January 19.

Anomaly in the Frontal Sinuses. Suarez de Mendoza.—In the case of a patient operated on for double frontal sinusitis, the inflammation recurred and two supplementary sinuses were found, separated by a thin partition from the true sinuses, but each with its separate passage into the nose. Mendoza has found a similar anomaly on two cadavers. Anger has mentioned this anomaly and Beco has recently reported a similar case.

Calcium Chlorid in Hemorrhagic Variola. Roger.—This article calls attention to the marked benefit derived from the use of calcium chlorid in many cases of hemorrhagic variola. Roger administers it in the following formula: crystallized calcium chlorid, 4 to 6 gm.; syrup of bitter orange peel, 40 gm.; brandy or rum, 30 gm.; tincture of cinnamon, 5 gm.; aq. dest., 50 gm. A tablespoonful is given every hour, supplemented by local hemostatic applications, gelatin, etc. If the hemorrhage is from the intestines they should be flushed with salt solution containing tannin or extract of rhatany.

Centralblatt f. Chir. (Leipsic), January 26.

Substitute for Gastroenterostomy. M. Schmidt.—In case of circumscribed stenosis or spasm of the pylorus, Schmidt suggests, after severing the duodenum from the pylorus, to insert the stump of the duodenum in the stomach, below the closed stump of the pylorus, and suture it to the posterior wall, "end-to-side," maintaining in this way the natural course of the passage, merely moving it a little farther down and farther inside the stomach.

Deutsche Med. Wochenschrift (Leipsic), January 24.

Instruction in the History of Medicine. E. Braatz.—Virchow wrote thirty years ago that the scientific knowledge of young physicians reaches only three to five years back, and this is equally true of the present generation. The history of medicine was taught as a regular branch in fifteen German-speaking universities, a few years ago, but it is kept up now in only two or three. Nevertheless the medical graduate needs the story of the past in order to appreciate the present, to uphold the traditions in professional ethics, and for many other reasons. Braatz pleads that this instruction should not be neglected, and also that more attention should be paid to the things necessary in general practice.

New Form of Hemoglobinuria. L. Michaelis.—In case of extrauterine pregnancy terminating in abortion through the abdominal ostium of the tube, and extensive hemorrhage into the abdominal cavity with severe clinical symptoms, no blood was evacuated through the vagina, and a small retro-uterine hematocele was the only palpable lesion. The patient rapidly recovered. During the absorption of the accumulation of blood, pronounced hemoglobinuria was present on two occasions, once for two and again for four days. Michaelis suggests that possibly the hemoglobin in the extravasated blood was absorbed unaltered into the blood and eliminated through the kidneys, but this phenomenon has never been observed before and is scarcely probable. Still more plausible, he thinks, is the assumption of the formation of a hemolysin by the rapid absorption of the extravasated blood. This hemolysin in turn acted on the blood corpuscles, dissolving them and inducing the hemoglobinemia and hemoglobinuria noted in the case. The formation of the autolysin is followed by the production of an anti-autolysin, as Ehrlich has established, but the latter does not keep pace with the former at first, and more or less hemolysis occurs before the latter is able to counteract the action of the autolysin.

Muenchener Med. Woch., January 8, 15 and 22.

Test for Indican in Urine Containing Iodin. A. Kuehn.—In testing urine for indican, the presence of iodin disturbs the reaction to the test. Kuehn announces that even one drop of a 5 per 1000 solution of sodium thiosulphate will combine the iodin in urine containing 1 per 1000 indican, into a colorless sodium compound.

Atavistic Deformities. G Klein.—In this preliminary communication Klein mentions, as examples of deformities in the female genitalia, which are merely a return to atavistic conditions, uterus bipartitus and double vagina and tubes. Opossums have normally a double uterus, double vagina and double tubes. In the hen, only one of Mueller's ducts develops; the other atrophies, in normal conditions.

January 15.

Subcutaneous Laceration of the Spleen. Jordan.—A case of traumatic, isolated laceration of the spleen is described, the patient, a young officer, who was thrown from his horse and fell on the hilt of his saber. The immediate pain was intense, but there was not much shock. Symptoms of inflammation of the peritoneum followed, and, later, of internal hemorrhage. The pain was localized in the liver region and there was also an area of dulness on the right as well as the left side. But the dulness of the spleen did not change with altered position, and consequently a liver lesion could be excluded. The abdominal wall was retracted and hard. A tear of the mesentery or omentum seldom entails such rapid and profuse hemorrhage as laceration of the spleen. The dulness over the liver, in addition to that in the left flank, indicated hemorrhage, as there is no area of dulness over the liver in case of isolated perforation of the intestine. Vincent could find only six spontaneous recoveries, with 134 deaths from more or less extensive laceration of the spleen. Lewerenz, however, has collected 15 spontaneous recoveries in 135 cases in which the injury to the spleen was the predominant or only serious trauma (*Langenbeck's Archiv* lx, 1900), 16 were saved by extirpation of the organ. The remaining 104 all died; no attempt at surgical intervention was made in 90 cases. Death occurred in less than twenty-four hours in 85 per cent., and in two or three days in 10 per cent., invariably from the hemorrhage or its consequences. The absence of anatomic confirmation of the spontaneous recoveries renders some of them doubtful. These statistics proclaim the necessity of immediate operation to arrest the hemorrhage. The operation of splenectomy has been performed in more than 300 cases besides innumerable experiments on animals, and there is not a single instance known to date in which the extirpation of the organ was in itself the cause of death. On the contrary, even when the blood-producing organs are taxed as after the extensive hemorrhage, the composition of the blood returns to normal in a few weeks or months. In Jordan's personal case the spleen was promptly removed, and two liters of blood were evacuated from the peritoneal cavity. Meteorism, vomiting and atony of the intestines ensued, probably the results of the contusion. Symptoms of circumscribed peritonitis in the vicinity of the stump of the spleen were also observed. Notwithstanding these complications, the patient had completely recovered his health in four months, with the exception of an occasional twinge of pain in the region, possibly caused by some adhesion. Nothing occurred during the entire course of the case which suggested a vicarious activity on the part of any other blood-producing organ. [In Savor's case, described in The Journal xxxii, p. 188, the removal of the spleen did not seem to have an unfavorable influence on the pregnant patient nor on the child delivered normally later. Riegner has recently reported that the patient whose spleen he removed eight years and nine months before, is in good health to date. This was the first case of extirpation of the spleen on account of rupture.—Ed.]

January 22.

Hereditary Transmission of Tuberculosis. E. Klebs.—The transmission of tuberculosis from a tuberculous father is ten times more dangerous for the offspring than from a tuberculous mother. Klebs bases this assertion on his experience and observation, particularly in Switzerland, where there is less shifting of population than in most countries. He tabulates the pathologic tree of two families with 55 descendants in five and six generations. It shows that when both parents were tuberculous, all the children became affected; that 46 per cent. became tuberculous when the father was infected, and that in twenty cases healthy children were raised by tuberculous mothers while only two healthy ones were born to tuberculous fathers. He remarks that if a life insurance company had insured these families—excluding children with tuberculous mothers and accepting those with infected fathers—it would have lost by the transaction. Tubercular peritonitis or nephritis was usually the first manifestation of infection in the children of tuberculous fathers, while the lungs and cervical ganglia were usually primarily affected in the children of infected mothers. The route of the infection in the latter case is probably through the lymphatic gland situated behind the sternoclavicular articulation, as Grober has established that stains injected into the tonsils pass not only into the cervical lymphatics, but also into the pleura and the apex of the lung. Tubercular infection of the apex is probably derived in many, if not in most, cases from infected glands in the neck and not from inhalation into the lungs. The percentage of descendants in the two families who died early or childless was 71.8. Only 28.2 per cent. had more than one child, and many of these were tuberculous.

Alcohol Vapor for Disinfection. G. Frank.—Anthrax spores exposed, between sheets of filtering paper, to the vapor of boiling 40 per cent. alcohol were invariably killed in five minutes in Frank's numerous tests. Steam alone and alcohol vapor alone are ineffectual. The bactericidal power is due to the combination of 90 per cent. alcohol and 12 per cent. water which pass off in the steam and vapor when 40 per cent. alcohol is boiled.

Condition of the Blood-Forming Organs in Anemia. C. S. Engel.—As the results of his researches, Engel concludes that it is possible to determine the condition of the bone-marrow in anemia from examination of the blood. He distinguishes four phases of the marrow: "normal, insufficient, metaplastic and aplastic." The normal red bone-marrow in the epiphyses contains orthochromatic and polychromatic normoblasts. The blood shows only one kind of red corpuscle, normal orthochromatic erythrocytes. In case of "insufficient" bone-marrow, the size and shape of the red corpuscles are the same as in normal conditions, but sometimes the nucleated reds in the bone-marrow are increased, as in case of pernicious anemia, in which metaplastic cells are observed in the marrow. The blood may be characteristic of chlorosis or of anemia, or pathologic reds may pass into the blood, normal in size, but such as remain in the marrow under normal conditions, orthochromatic and polychromatic normoblasts and polychromatic erythrocytes. In metaplastic marrow the yellow portion is entirely or partially red. Megaloblasts and metrocytes are found in the marrow, such as are noted in the earliest embryonal stages in the blood of the heart and liver, before any bone-marrow has developed. The cells of metaplastic bone-marrow are therefore identical with the blood cells of the premedullary period of blood formation, and show all the transitions from normal size to pathologically large red corpuscles with and without a nucleus. Megaloblasts are found frequently and macrocytes regularly in the blood. In the rare condition which he calls "aplastic" bone-marrow, no nucleated reds nor leucocytes are found. The red marrow of the epiphyses has become transformed into fatty marrow and ceases to be a hematopoietic organ. No pathologic cells are found in the blood; the normal red corpuscles diminish without being substituted by others. Even granulated leucocytes are absent. Engel urges, in conclusion, microscopic examination of the red marrow at every autopsy as a routine measure.

Evacuation of Abscesses in Retrovesical Pouch Through a Parasacral Incision. K. Port.—Rotter recommends the rectal route for opening abscesses in the rectovesical pouch, but Port is convinced that a much simpler and safer way is that described by C. Koch (*Muench. Med. Woch.*, 1899, 1.) He had occasion to perform this operation recently and found it extremely satisfactory. The broad, funnel-shaped, parasacral opening afforded ample view of the conditions in the region. The incision was carried around the left of the anus to the apex of the coccyx and along its left margin. The coccyx was then turned back. The dressings were changed with the patient in the knee-elbow position. The abscess was consecutive to appendicitis, and after a necrotic fragment of tissue, possibly the appendix, had been expelled the wound rapidly healed. There was considerable pain during the first day or so from the luxated coccyx, but it soon subsided. As the pus has such a free outlet there is no fear of infiltration of adjacent tissues.

Perforation of Hydatid Cysts Into Lungs. S. Zervos.—In six cases of hydatid cysts perforating into the lungs, Zervos found the cysts in the upper surface of the liver. The French method of treating hydatid cysts by capitonage is not only ineffectual, but it exposes the patient to the greatest dangers. The cysts form again and as the hermetic suturing of the liver prevents them from developing forward and downward, they can only grow upward. This, in time, leads to perforation into the lung and death from immediate asphyxia or from pneumonia later.

Grece Medicale (Syra), December.

Malaria and Antirabic Treatment. Pampoukis.—At the Pasteur Institute in Athens it has been noted that a malarial chill and fever frequently follow the antirabic injection in patients who have previously suffered from malaria, but have had no attacks for a year or more.

Hematoblasts in the Omentum. Melissinos.—Hematoblasts such as are found in the other blood-producing organs have been discovered by Melissinos in the great omentum of cats, dogs, pigs and man during the embryonal stage. They are most numerous in that portion of the omentum between the spleen and the greater curvature. The great omentum and the spleen are both derived from the posterior mesogastrium, and as similar hematoblasts are found in each, this fact may throw some light on the origin of hematoblasts in general.

Gazetta Degli Ospedali (Milan), January 6, 13 and 20.

Physiology of the Cerebrospinal Fluid. Cavazzani.—The alkalinity of the cerebrospinal fluid was less than half that of the blood in a series of tests on dogs and cattle. The animals were under the influence of curare or morphin in some of the tests; in others the fluid was aspirated through the atlanto-occipital membrane or obtained post-mortem, and in another series of experiments, acids and alkalies were injected. The results all tend to demonstrate the existence in the nerve-centers of an acid substance resulting from their functional activity. Cavazzani also announces that he has succeeded in precipitating a substance from the cerebrospinal fluid which behaves like a ferment, an oxydase. Further researches indicated that the variations in pressure are due to the venous circulation. He noticed that at the commencement of asphyxia the pressure was diminished and the fluid ceased to flow from the fistula, followed soon by an increased flow. He also observed that the flow subsided in dogs on stimulation of the central stump of the vago-sympathetic nerve.

January 13.

Regeneration of Nerve Fibers. A Stefani.—This work won the prize offered by the Royal Institute of Lombardy. The researches therein detailed confirm the assumption that nerve fibers possess the property of maintaining the isolation of the central stumps as long as they remain normal. On the other hand, if one of the fibers or of the disconnected centers is in course of degeneration, union between the fibers may occur. The facts observed corroborate the conception of the neuron as an elementary organism with the property of keeping itself distinct from all other elementary organisms of the same species and of regenerating a lost part.

January 20.

Surgical Intervention in Bubonic Plague. Bandi.—The benefits of excising the buboes in oriental plague were proclaimed by Terni during his experiences in Brazil. Bandi has been conducting a long series of experiments in this line at Messina, and announces that the results completely confirm Terni's statements. He considers bubonic plague essentially and exclusively an affection of the lymphatic system. The bacillus settles in the gland first invaded and remains there for a time. Before the suppurative stage has been reached the bacilli start on their invading progress, passing into adjacent glands, but without penetrating the capsular filter of the glands. The infection in his experiments always proceeded to the superficial glands before invading those that lay deeper. Prompt, aggressive extirpation of the primary foci is indicated. The bacilli do not pass into the blood except as a septicemic process in extremely severe cases, or when the resistance of the organism has been overcome. Salomoni states that he has removed tumefied glands as a local curative and general prophylactic measure in tuberculosis. He has systematically removed all the inguino-crural and pelvic glands in fourteen cases. He has also proved on the cadaver the feasibility of the enucleation of the peribronchial lymphatic glands.

Klinitchesky Journal (Moscow), November.

Two Cases of Cortical Epilepsy Treated by Operation. M. A. Luntz.—Both of the patients were women, one a cook, 53, and the other 22 years of age. There was no history nor indication of syphilis or trauma in either case; the typical cortical epilepsy was recent and the absence of general symptoms and other signs excluded the idea of a tumor. The epilepsy in the older woman had commenced after a very severe cold which had left great weakness; the seizures recurred at intervals of two or three weeks and sometimes for two or three days in succession. Luntz was able to diagnose positively the site of the lesion in the upper part of the central convolutions, but the alterations found at the spot were comparatively insignificant, merely a thickening of the dura mater and slight adhesions between the membranes, bone and brain. The lesion was evidently, he considers, a relic of an organic process, in all probability tubercular. Although none of the organs showed tubercular involvement, the patient had had, twenty-eight years before, an obstinate suppurating lesion in the left shoulder, which persisted for five years and left a deep defect. After craniectomy, in July, 1899, the slight paresis of the lower extremity persisted unchanged, but the seizures did not recur during the three months the patient was under observation. In the second case the operation proved a failure, as the seizures were uninfluenced. The lesion in this case was located in the lower and partly in the middle parts of the central convolutions. In the review of the current Russian periodicals, which is a new feature of this journal, another case of cortical epilepsy is described by Vassilieff, of fifteen years' standing, the epileptic and later the paralytic symptoms being limited to the left side. The patient died of intercurrent pneumonia, and a dark-red focus the size of a pea was found in the depths of the right fissure of Rolando. During the epileptic seizures in this case, the patient invariably lost consciousness if he were turned on his back.

Change of Address.

E. S. Alexander, 6424 Lowe St., to 267 S. Hermitage Ave., Chicago.

W. F. Seymour, Chicago, to Tengchowfoo, Shantung Prov., via Chefoo, China.

W. F. Sihler, Grand Harbor, to Devil's Lake, N. D.

J. O. Strickland, Atlanta, to Stilson, Ga.

C. H. Stoddard, 1201 State, to 1201 Vliet St., Milwaukee, Wis.

W. E. Shook, 740 Jackson Boul., to 588 Congress St., Chicago.

S. L. Stevens, 722 Jackson Boul., to 212 S. Lincoln St., Chicago.

R. B. Sweet, 775 Polk St., to 119 Seeley Ave., Chicago.

N. M. Spradley, Selvin, to Tennyson, Ind.

Percy Shields, 22 W 7th St., to 5 Garfield Pl., Cincinnati, Ohio.

W. D. Shields, Holdrege, to Insane Hospt., Lincoln, Neb.

A. L. Sherman, Hudson St. Hospt., to New York Hospt., New York City.

R. T. Strange, Memphis, Tenn., to Vandervoort, Ark.

E. J. Thayer, Yoakum, Tex., to 1645 Welton St., Denver, Colo.

N. K. Vance, Baton Rouge, to Shreveport, La.

J. M. Womeldorf, Hartley, to Schleswig, Iowa.

John Wehrly, St. Louis, Mo., to San Bernardino, Cal.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Jan. 24, to 30, 1901, inclusive:

Dallas Bache, colonel, asst.-surgeon-general U. S. A., president of a promotion board convened at the War Department, Washington, D. C.

Joseph L. Bell, acting asst.-surgeon, from Richmond, Ind., to duty at Fort Crook, Neb.

W. Fitzhugh Carter, major and surgeon, U. S. A., member of a board at Fort Totten, N. Y., to examine officers of the corps of engineers for promotion.

William D. Crosby, captain and asst.-surgeon, U. S. A., member of a board in New York City, to examine officers of the Ordnance Department.

Lawrence A. Felder, acting asst.-surgeon, member of a board at Mobile, Ala., to examine officers of the corps of engineers.

Alfred C. Girard, lieut.-col., deputy surgeon-general, U. S. A., member of a board at San Francisco, Cal., to examine officers of the corps of engineers.

Louis T. Hess, lieutenant and asst.-surgeon, U. S. A., now on temporary duty at the general hospital, Presidio of San Francisco, Cal., is relieved from further duty in the Division of the Philippines.

John Van R. Hoff, major and surgeon, U. S. A., member of a promotion board at the War Department, relieving Colonel Dallas Bache, asst.-surgeon-general.

Deane C. Howard, captain and asst.-surgeon, U. S. A., former orders from Fort Hancock, N. J., to the Division of the Philippines revoked.

Henry S. Kilbourne, major and surgeon, U. S. A., member of a board in New York City, to examine officers of the Ordnance Department.

Thomas J. Kirkpatrick, captain and asst.-surgeon, U. S. A., member of a board at Mobile, Ala., to examine officers of the corps of engineers.

Louis A. LaGarde, major and surgeon, U. S. A., member of a promotion board at the War Department, relieving Lieut.-Col. Charles Smart, deputy surgeon-general.

William C. LeCompte, acting asst.-surgeon, from Washington, D. C., to duty at Fort Du Pont, Del.

Thomas K. Mullins, acting asst.-surgeon, leave of absence granted.

George Newlove, acting asst.-surgeon, former orders modified so as to assign him to temporary duty at Fort Sill, Okla.

Robert M. O'Reilly, lieut.-col., deputy surgeon-general, U. S. A., member of a board at Fort Monroe, Va.; to examine officers of the army.

Adrian S. Polhemus, captain and asst.-surgeon, U. S. A., now on duty at Fort Leavenworth, Kan., to proceed to Fort Riley, Kan., for temporary duty, and as a member of a promotion board.

Benjamin F. Pope, lieut.-col., deputy surgeon-general U. S. A. member of a board at San Francisco Cal., to examine officers of the corps of engineers for promotion.

Irving W. Rand, captain and asst.-surgeon, U. S. A., former orders assigning him to Fort Hancock, N. J., from the Division of the Philippines revoked.

Charles Smart, lieut.-col., deputy surgeon-general, U. S. A., member of a promotion board at the War Department, Washington, D. C.

James K. Stockard, acting asst.-surgeon, now in San Francisco, Cal., is assigned to duty in the Department of California.

Blair D. Taylor, major and surgeon, U. S. A., member of a board at Honolulu, H. I., to examine candidates for admission into the U. S. Military Academy, West Point, N. Y.

Adrian D. Williams, acting asst.-surgeon, from Brooklyn, N. Y., to temporary duty at Fort Adams, R. I.

Roy A. Wilson, acting asst.-surgeon, member of a board at Fort Totten, N. Y., to examine officers of the corps of engineers for promotion.

Navy Changes.

Changes in the Medical Corps of the navy for the week ending Feb. 2, 1901:

Medical Inspector W. A. McClurg, commissioned medical inspector, Nov. 19, 1900:

Asst.-Surgeon H. C. Shiffert, ordered to the *Franklin*.

Asst.-Surgeon E. J. Grow, detached from the *Culgoa*, and ordered to the *Glacier*, and also to duty at Olongape, P. I.

Pharmacist J. Cowan, detached from the *Culgoa*, and ordered to the *Glacier*, and also to duty at the Naval Hospital, Cavite.

P. A. Surgeon M. R. Pigott, died at Annapolis, Md., January 31, 1901.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioner officers of the U. S. Marine-Hospital Service for the seven days ended Jan. 31, 1901:

Surgeon W. P. McIntosh, to proceed to Jeffersonville, Ga., for special temporary duty, Jan. 30, 1901.

Surgeon T. B. Perry, granted leave of absence for thirty days from Feb. 11.

Asst.-Surgeon John McMullen, upon expiration of leave of absence, to proceed to Wilmington, N. C., and assume temporary command of the service during the absence of Surgeon T. B. Perry.

Asst.-Surgeon G. M. Corput, to proceed to Cleveland, Ohio, and assume temporary command of the service during the absence of Surgeon W. J. Pettus.

BOARD CONVENED.

Board convened to meet at Washington, D. C., on Tuesday, Feb. 5, 1901, for the physical examination of Second Asst.-Engineer R. F. Halpin, R. C. S. Detail for the board—Surgeon Preston H. Bailhache, Chairman; Surgeon G. T. Vaughan, and Asst.-Surgeon B. S. Warren, Recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Feb. 2, 1901:

SMALLPOX—UNITED STATES.

District of Columbia: Washington, Jan. 19-26, 2 cases
Florida: Jacksonville, Jan. 12-26, 10 cases.
Illinois: Chicago, Jan. 19-26, 25 cases, 1 death.
Indiana: Michigan City, Jan. 20-27, 1 case.
Kansas: Wichita, Jan. 19-26, 9 cases.
Kentucky: Lexington, Jan. 19-26, 2 cases.
Louisiana; Jan. 19-26, Shreveport, 5 cases; New Orleans, 11 cases, 3 deaths.
Maryland: Baltimore, Jan. 19-26, 1 case.
Pennsylvania: Jan. 19-26, Erie, 1 case: Pittsburg, 2 cases.
Tennessee: Jan. 19-26, Memphis, 8 cases; Nashville, 4 cases.
Texas: Houston, Jan. 19-26, 44 cases, 1 death.
Utah: Salt Lake City, Jan. 19-26, 31 cases.
Wisconsin: Milwaukee, Jan. 19-26, 1 case.

SMALLPOX—FOREIGN.

Belgium: Antwerp, Dec. 29-Jan. 5, 1 case.
Brazil: Pernambuco, Nov. 15-30, 30 deaths.
China: Hongkong, Dec. 8-15, 1 case.
Egypt: Alexandria, Dec. 24-31, 2 cases, 1 death.
England: Jan. 5-12, London, 1 case; Newcastle, on Tyne, 2 cases.
France: Paris, Jan. 5-12, 11 deaths.
India: Bombay, Dec. 24-Jan. 1, 4 deaths.
Mexico: Mexico, Jan. 13-20, 1 case; Tuxpan, Jan. 14-21, 1 death; Vera Cruz, Jan. 6-13, 3 cases.
Russia: Moscow, Dec. 22-Jan. 5, 9 cases, 4 deaths; Odessa, Dec. 22-Jan. 12, 137 cases, 24 deaths; St. Petersburg, Dec. 22-Jan. 5, 6 cases 2 deaths; Warsaw, Dec. 22-Jan. 5, 23 deaths.
Scotland: Glasgow, Jan. 11-18, 121 cases, 2 deaths.

YELLOW FEVER.

Cuba: Havana, Jan. 12-19, 2 deaths.
Mexico: Vera Cruz, Jan. 6-20, 5 cases.

CHOLERA.

India: Bombay, Dec. 24-Jan. 1, 2 deaths.
Straits Settlements: Singapore, Nov. 16-27, 36 cases, 36 deaths.

PLAGUE.

India: Bombay, Dec. 24-Jan. 1, 154 deaths.
Turkey: Constantinople, Jan. 7, 1 death.

THE BACTERIAL TOXINS.*

VICTOR C. VAUGHAN, M.D., AND THOMAS B. COOLEY, M.D.

ANN ARBOR, MICH.

Our object in presenting this paper is merely to outline the theory of the nature and action of the bacterial toxins which we are endeavoring to demonstrate, and to describe our method of work and the results which we have reached through the experiments we have so far made, which are very incomplete and really only a beginning toward the thorough working out of the subject.

We have been led by observation of many facts concerning the pathogenic bacteria and their action in the various infectious diseases, their resistance to heat, to disinfectants and stains, etc., and by the results of some investigations carried on by others and by ourselves with certain species of these organisms to formulate a theory which we believe to be in some respects new, and which may be stated as follows: The specific poisons of the pathogenic bacteria are formed within the bacterial cells, and constitute a part of the organism itself. As we shall mention later, this idea has been held by others, notably by Buchner and by Pfeiffer. Bacteria probably consist of cell membranes with contents in which the poison exists. In at least some of the pathogenic bacteria the toxin does not appear to be an essential part of the cell. We mean by this that some of the pathogenic bacteria may retain their vitality and still not manifest their pathogenic properties. This is well illustrated by de Schweinitz and others in their studies of the tubercle bacillus.

The pathogenic properties of a given bacterium are dependent on the poisonous character of the cell contents and the readiness with which the content is diffused through the cell wall, and this diffusibility is dependent on the solubility of the toxin and the permeability of the cell wall.

An increase or decrease in the virulence of a given bacterium can be explained in only one of two ways. The first possibility is that it is due to a chemical change in the toxin itself. This seems to us highly improbable. The second possibility is that heightened virulence is due to an increase in the amount of the toxin formed within the cell or to a greater permeability of the cell wall, one or both. The third possibility, that increased virulence may be due to more rapid cell proliferation, we reject as a rule, because it is well known that from some cultures of the diphtheria bacillus a more active toxin may be obtained than from other cultures in which there is more abundant cell growth. The relative proportion of cell membrane and toxin content is probably a variable one. It is furthermore probable that with increased cell content the cell wall becomes both thinner and more permeable.

It is probable that the toxins of the different pathogenic bacteria belong chemically to the same group of bodies and that they are proteid in character. Apparently these toxins vary in stability of constitution. This is indicated by the difference in the effect of heat upon them. As we shall show, the toxin of the colon bacillus may be heated with water in a sealed tube, to 184 degrees for one-half hour without decrease in virulence while the cells of the diphtheria bacillus become inert after prolonged exposure to a temperature of 60 degrees. That the cell walls differ in the readiness with which their toxin contents diffuse through them seems evident from the way in which diphtheria and tetanus bacilli induce intoxications while their growth is confined to a very limited area, as compared with the relative innocuousness of the colon bacillus growing abundantly in the intestines, and at the same time containing a highly active toxin.

This theory will require a long series of observations of the characteristics and action of many bacteria before its truth or falsity can be determined, but we believe that we have in the investigations we have carried on during the past few months established, in regard to the bacillus, the bacterium coli commune, certain facts which have an important bearing on the question, and which we hope may lead us in time toward further light on the chemistry of the bacterial toxins; and we feel sure that only when we have light on the chemistry of these toxins will the nature and action of the antitoxins be understood.

The literature of bacteriology and hygiene gives little information concerning our subject. A thorough examination of the publications within our reach shows that although a vast amount of work has been expended on the isolation and identification of some of the bacterial toxins, the progress made has been slow. In fact, it may safely be said that in no case has the chemical nature of the essential toxin of any of the pathogenic bacteria been shown. In the case of the group with which we are at present working, that of the colon bacilli, almost nothing of any real importance has been done toward showing the nature of their toxin; and investigations with any of the pathogenic bacteria along the line in which we are working, namely, the isolation and indentification of a poison which is an essential part of the cell content, aside from any poison which may or may not be dissolved in the medium surrounding the cell, are very rare.

A few communications are, however, worthy of especial notice. Two prominent observers have emphatically stated their belief in bacterial toxins which are an essential part of the bacteria themselves—Buchner in regard to the pathogenic organisms in general, and

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Jan. 24, to 30, 1901, inclusive:

Dallas Bache, colonel, asst.-surgeon-general U. S. A., president of a promotion board convened at the War Department, Washington, D. C.

Joseph L. Bell, acting asst.-surgeon, from Richmond, Ind., to duty at Fort Crook, Neb.

W. Fitzhugh Carter, major and surgeon, U. S. A., member of a board at Fort Totten, N. Y., to examine officers of the corps of engineers for promotion.

William D. Crosby, captain and asst.-surgeon, U. S. A., member of a board in New York City, to examine officers of the Ordnance Department.

Lawrence A. Felder, acting asst.-surgeon, member of a board at Mobile, Ala., to examine officers of the corps of engineers.

Alfred C. Girard, lieut.-col., deputy surgeon-general, U. S. A., member of a board at San Francisco, Cal., to examine officers of the corps of engineers.

Louis T. Hess, lieutenant and asst.-surgeon, U. S. A., now on temporary duty at the general hospital, Presidio of San Francisco, Cal., is relieved from further duty in the Division of the Philippines.

John Van R. Hoff, major and surgeon, U. S. A., member of a promotion board at the War Department, relieving Colonel Dallas Bache, asst.-surgeon-general.

Deane C. Howard, captain and asst.-surgeon, U. S. A., former orders from Fort Hancock, N. J., to the Division of the Philippines revoked.

Henry S. Kilbourne, major and surgeon, U. S. A., member of a board in New York City, to examine officers of the Ordnance Department.

Thomas J. Kirkpatrick, captain and asst.-surgeon, U. S. A., member of a board at Mobile, Ala., to examine officers of the corps of engineers.

Louis A. LaGarde, major and surgeon, U. S. A., member of a promotion board at the War Department, relieving Lieut.-Col. Charles Smart, deputy surgeon-general.

William C. LeCompte, acting asst.-surgeon, from Washington, D. C., to duty at Fort Du Pont, Del.

Thomas K. Mullins, acting asst.-surgeon, leave of absence granted.

George Newlove, acting asst.-surgeon, former orders modified so as to assign him to temporary duty at Fort Sill, Okla.

Robert M. O'Reilly, lieut.-col., deputy surgeon-general, U. S. A., member of a board at Fort Monroe, Va., to examine officers of the army.

Adrian S. Polhemus, captain and asst.-surgeon, U. S. A., now on duty at Fort Leavenworth, Kan., to proceed to Fort Riley, Kan., for temporary duty, and as a member of a promotion board.

Benjamin F. Pope, lieut.-col., deputy surgeon-general U. S. A. member of a board at San Francisco Cal., to examine officers of the corps of engineers for promotion.

Irving W. Rand, captain and asst.-surgeon, U. S. A., former orders assigning him to Fort Hancock, N. J., from the Division of the Philippines revoked.

Charles Smart, lieut.-col., deputy surgeon-general, U. S. A., member of a promotion board at the War Department, Washington, D. C.

James K. Stockard, acting asst.-surgeon, now in San Francisco, Cal., is assigned to duty in the Department of California.

Blair D. Taylor, major and surgeon, U. S. A., member of a board at Honolulu, H. I., to examine candidates for admission into the U. S. Military Academy, West Point, N. Y.

Adrian D. Williams, acting asst.-surgeon, from Brooklyn, N. Y., to temporary duty at Fort Adams, R. I.

Roy A. Wilson, acting asst.-surgeon, member of a board at For Totten, N. Y., to examine officers of the corps of engineers for promotion.

Navy Changes.

Changes in the Medical Corps of the navy for the week ending Feb. 2, 1901:

Medical Inspector W. A. McClurg, commissioned medical inspector, Nov. 19, 1900:

Asst.-Surgeon H. C. Shiffert, ordered to the *Franklin*.

Asst.-Surgeon E. J. Grow, detached from the *Culgoa*, and ordered to the *Glacier*, and also to duty at Olongape, P. I.

Pharmacist J. Cowan, detached from the *Culgoa*, and ordered to the *Glacier*, and also to duty at the Naval Hospital, Cavite.

P. A. Surgeon M. R. Pigott, died at Annapolis, Md., January 31, 1901.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioner officers of the U. S. Marine-Hospital Service for the seven days ended Jan. 31, 1901:

Surgeon W. P. McIntosh, to proceed to Jeffersonville, Ga., for special temporary duty, Jan. 30, 1901.

Surgeon T. B. Perry, granted leave of absence for thirty days from Feb. 11.

Asst.-Surgeon John McMullen, upon expiration of leave of absence, to proceed to Wilmington, N. C., and assume temporary command of the service during the absence of Surgeon T. B. Perry.

Asst.-Surgeon G. M. Corput, to proceed to Cleveland, Ohio, and assume temporary command of the service during the absence of Surgeon W. J. Pettus.

BOARD CONVENED.

Board convened to meet at Washington, D. C., on Tuesday, Feb. 5, 1901, for the physical examination of Second Asst.-Engineer R. F. Halpin, R. C. S. Detail for the board—Surgeon Preston H. Bailhache, Chairman; Surgeon G. T. Vaughan, and Asst.-Surgeon B. S. Warren, Recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Feb. 2, 1901:

SMALLPOX—UNITED STATES.

District of Columbia: Washington, Jan. 19-26, 2 cases

Florida: Jacksonville, Jan. 12-26, 10 cases.

Illinois: Chicago, Jan. 19-26, 25 cases, 1 death.

Indiana: Michigan City, Jan. 20-27, 1 case.

Kansas: Wichita, Jan. 19-26, 9 cases.

Kentucky: Lexington, Jan. 19-26, 2 cases.

Louisiana; Jan. 19-26, Shreveport, 5 cases; New Orleans, 11 cases, 3 deaths.

Maryland: Baltimore, Jan. 19-26, 1 case.

Pennsylvania: Jan. 19-26, Erie, 1 case: Pittsburg, 2 cases.

Tennessee: Jan. 19-26, Memphis, 8 cases: Nashville, 4 cases.

[illegible] 19-26, 44 cases, 1 death.

[illegible] Jan. 19-26, 31 cases.

[illegible] Jan. 19-26, 1 case.

SMALLPOX—FOREIGN.

Belgium: Antwerp, Dec. 29-Jan. 5, 1 case.

Brazil: [illegible]-30, 30 deaths.

China: [illegible] 1 case.

Egypt: [illegible] 1, 2 cases, 1 death.

England: [illegible] 1 case; Newcastle, on Tyne, 2 cases.

France: Paris, Jan. 5-12, 11 deaths.

India: Bombay, Dec. 24-Jan. 1, 4 deaths.

Mexico: Mexico, Jan. 13-20, 1 case; Tuxpan, Jan. 14-21, 1 death: Vera Cruz, Jan. 6-13, 3 cases.

Russia: Moscow, Dec. 22-Jan. 5, 9 cases, 4 deaths; Odessa, Dec. 22-Jan. 12, 137 cases, 24 deaths: St. Petersburg, Dec. 22-Jan. 5, 6 cases 2 deaths; Warsaw, Dec. 22-Jan. 5, 23 deaths.

Scotland: Glasgow, Jan. 11-18, 121 cases, 2 deaths.

YELLOW FEVER.

Cuba: Havana, Jan. 12-19, 2 deaths.

Mexico: Vera Cruz, Jan. 6-20, 5 cases.

CHOLERA.

India: Bombay, Dec. 24-Jan. 1, 2 deaths.

Straits Settlements: Singapore, Nov. 16-27, 36 cases, 36 deaths.

PLAGUE.

India: Bombay, Dec. 24-Jan. 1, 154 deaths.

Turkey: Constantinople, Jan. 7, 1 death.

THE BACTERIAL TOXINS.*

VICTOR C. VAUGHAN, M.D., and THOMAS B. COOLEY, M.D.
ANN ARBOR, MICH.

Our object in presenting this paper is merely to outline the theory of the nature and action of the bacterial toxins which we are endeavoring to demonstrate, and to describe our method of work and the results which we have reached through the experiments we have so far made, which are very incomplete and really only a beginning toward the thorough working out of the subject.

We have been led by observation of many facts concerning the pathogenic bacteria and their action in the various infectious diseases, their resistance to heat, to disinfectants and stains, etc., and by the results of some investigations carried on by others and by ourselves with certain species of these organisms to formulate a theory which we believe to be in some respects new, and which may be stated as follows: The specific poisons of the pathogenic bacteria are formed within the bacterial cells, and constitute a part of the organism itself. As we shall mention later, this idea has been held by others, notably by Buchner and by Pfeiffer. Bacteria probably consist of cell membranes with contents in which the poison exists. In at least some of the pathogenic bacteria the toxin does not appear to be an essential part of the cell. We mean by this that some of the pathogenic bacteria may retain their vitality and still not manifest their pathogenic properties. This is well illustrated by de Schweinitz and others in their studies of the tubercle bacillus.

The pathogenic properties of a given bacterium are dependent on the poisonous character of the cell contents and the readiness with which the content is diffused through the cell wall, and this diffusibility is dependent on the solubility of the toxin and the permeability of the cell wall.

An increase or decrease in the virulence of a given bacterium can be explained in only one of two ways. The first possibility is that it is due to a chemical change in the toxin itself. This seems to us highly improbable. The second possibility is that heightened virulence is due to an increase in the amount of the toxin formed within the cell or to a greater permeability of the cell wall, one or both. The third possibility, that increased virulence may be due to more rapid cell proliferation, we reject as a rule, because it is well known that from some cultures of the diphtheria bacillus a more active toxin may be obtained than from other cultures in which there is more abundant cell growth. The relative proportion of cell membrane and toxin content is probably a variable one. It is furthermore probable that with increased cell content the cell wall becomes both thinner and more permeable.

It is probable that the toxins of the different pathogenic bacteria belong chemically to the same group of bodies and that they are proteid in character. Apparently these toxins vary in stability of constitution. This is indicated by the difference in the effect of heat upon them. As we shall show, the toxin of the colon bacillus may be heated with water in a sealed tube, to 184 degrees for one-half hour without decrease in virulence while the cells of the diphtheria bacillus become inert after prolonged exposure to a temperature of 60 degrees. That the cell walls differ in the readiness with which their toxin contents diffuse through them seems evident from the way in which diphtheria and tetanus bacilli induce intoxications while their growth is confined to a very limited area, as compared with the relative innocuousness of the colon bacillus growing abundantly in the intestines, and at the same time containing a highly active toxin.

This theory will require a long series of observations of the characteristics and action of many bacteria before its truth or falsity can be determined. but we believe that we have in the investigations we have carried on during the past few months established, in regard to the bacillus, the bacterium coli commune, certain facts which have an important bearing on the question, and which we hope may lead us in time toward further light on the chemistry of the bacterial toxins; and we feel sure that only when we have light on the chemistry of these toxins will the nature and action of the antitoxins be understood.

The literature of bacteriology and hygiene gives little information concerning our subject. A thorough examination of the publications within our reach shows that although a vast amount of work has been expended on the isolation and identification of some of the bacterial toxins, the progress made has been slow. In fact, it may safely be said that in no case has the chemical nature of the essential toxin of any of the pathogenic bacteria been shown. In the case of the group with which we are at present working, that of the colon bacilli, almost nothing of any real importance has been done toward showing the nature of their toxins; and investigations with any of the pathogenic bacteria along the line in which we are working, namely, the isolation and indentification of a poison which is an essential part of the cell content, aside from any poison which may or may not be dissolved in the medium surrounding the cell, are very rare.

A few communications are, however, worthy of especial notice. Two prominent observers have emphatically stated their belief in bacterial toxins which are an essential part of the bacteria themselves—Buchner in regard to the pathogenic organisms in general, and

*Presented to the Section on Pathology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Pfeiffer in regard to the vibrio of Asiatic cholera. Buchner[1] describes his investigations on pus-producing substances in bacterial cells. The chief interest of these papers in the present connection lies in the statement of his belief that there is nothing in the whole category of decomposition products, caused by bacteria, to account for the phenomena of the general infectious diseases, but that the cause of these must be looked for in the albuminates of the bacterial cell itself, and that in some cases, at least, these poisons are only set free on the death and dissolution of the bacterial cell. By this theory he explains the fact that suppuration may be caused by dead cultures of germs which, when living, have not the pyogenic property. Further interest attaches to the similarity of his method of extracting the toxin to those used by ourselves. He first mentions various experiments going to show that sterilized cultures of certain bacteria have the same effect as the living cultures, and others showing that this effect is not due to the mechanical irritation caused by the dead germ. He showed also, by heating with steam under pressure at 120 degrees and by distillation, that the poisonous properties of the culture—in this case the pneumobacillus of Friedlaender—were not due to a readily decomposed or volatile substance. He then boiled his bacterial emulsion in a flask with a reflux condenser, and allowed it to settle, thereby obtaining a bacterial layer under a layer of clear fluid. Comparative injections showed that the poisonous principle was contained only in the germ layer. He carried out similar investigations with seventeen different varieties of bacteria, among which was the colon bacillus. In these he took the growth from agar or potato, rubbed it up to a thick emulsion with water, heated for one hour at 100 degrees and allowed it to settle. In all cases the injection of 1 c.c. of the emulsion after heating produced sterile pus-infiltration at the point of injection. In three cases only after settling did he obtain a clear fluid overlying the germ layer, and in these cases the fluid was non-toxic, while the germ layer caused intense pus formation.

In order to isolate the pyogenic substance from the bacterial cells, he added to the bacterial mass obtained from agar or potato about 20 volumes of .5 per cent. solution of potassium hydrate, obtaining thereby a mucilaginous mass which dissolved at the temperature of the water-bath. A clear fluid was obtained by repeated filtration, and from this the proteins were precipitated by acidifying and purified by resolution in alkali, reprecipitation and final resolution in just enough soda to neutralize the acid in the precipitate. The proteid thus obtained was found to have the pyogenic properties of the original bacterial emulsion. Similar results were obtained with a number of germs, though the most work was done with the pneumobacillus. Although the colon bacillus was one of those worked with, it is to be noted that no mention is made of a poisonous proteid being isolated from it by these methods, and, in fact, we were unable to extract any poisonous substance from this germ by means of dilute alkali.

Pfeiffer's[2] work on the cholera vibrio was carried out with the purpose of proving that the specific poison of this particular disease is a part of the cell content of the organism which is liberated and absorbed only on the death of the vibrio. His method was as follows: Having secured a virulent culture of the vibrio, he made a series of comparative inoculations with cultures treated: 1, by boiling; 2, by passing through a porcelain filter, and afterward heating in the steam bath for one-half hour; 3, by boiling and then passing through porcelain; 4, simply by rubbing up with small quantities of bouillon, living cultures; 5, by killing with chloroform vapor; 6, by killing with thymol; 7, by killing with absolute alcohol; 8, with concentrated solution of ammonium sulphate for twenty-four hours; 9, by drying; 10, by dry heat sterilization; 11, by passing a twenty-days-old 4 per cent. glycerin bouillon culture through porcelain; 12, by passing the glycerin extract of a fresh culture through porcelain. In 1, 3, 4, 5, 6, 7, 8, 9, and 10, the results were positive, the animals either dying or being severely affected, with very similar symptoms in all cases, the most marked of which was the rapid fall of temperature. In 2, 11 and 12 the animals were either not affected or affected very slightly. In 4, a minimum dose was established, smaller for intraperitoneal than for submucous injections, and smaller doses caused an illness terminating in recovery. Cultures made after death, from intra-abdominal injections, did not show multiplication of the germs, and, as a rule, showed diminution in number. Nor were the germs found in the intestines or organs. Pfeiffer did not succeed in isolating and purifying a chemical poison. His conclusion that the cholera poison was a constituent of the cell and liberated only on its death and dissolution was combated more than once, especially by Metchnikoff, Roux, and Salimbeni,[3] who put in collodion sacs living bouillon cultures of the cholera vibrio, and cultures killed by chloroform, and found that when these sacs were placed in the peritoneal cavities of animals, the living cultures caused death in a short time with all the symptoms of cholera, while the dead germs had much less poisonous power. Whether or not these experiments of Metchnikoff and his associate disprove Pfeiffer's theory that the poison of the cholera vibrio is liberated only after the death of the organism, is questionable, but at any rate they have no bearing on our theory.

The literature relating to the toxin of the colon bacillus is very meager. Kiessling[4] gives a thorough summary of all work done on this bacillus up to that time. Under the heading of "The Pathological Significance of the Colon Bacillus," he describes the investigations of a number of observers, beginning with those of Emmerich on his "Bacillus Neapolitanus," in 1885, most of which are not of interest in the present connection, as they were concerned with the pathogenic action of the living germ. However, Gilbert,[5] in 1893, demonstrated the poisonous properties of filtered cultures of this bacillus. He injected these cultures intravenously into rabbits, and though they were not uniformly poisonous in the same degree, there resulted paralysis of the striped muscle fibers with blunting of sensibilities and coma; then convulsions, nystagmus, and heightened sensitiveness and reflexes; and finally contractures and death. During the first two stages recovery was still possible, but in the last death was inevitable. Gilbert also concluded from his observations, that the poison was destroyed in the liver and kidneys. Roger,[6] in 1893, described an analogous action of the toxin on frogs. Wyssokowitsch,[7] in 1886, observed that the colon bacillus, when injected into the blood, appeared quickly and in large numbers in the intestines, and as this is possible only through alteration of the intestinal walls he concluded that with the micro-organism there is brought into the circulation some poisonous substance which causes marked gastro-enteritis and deep lesions of the mucous coat of the intestinal wall. On the other hand, Baginsky[8] was unable to obtain from nitrogenous food contaminated with this organism any substance having a poisonous action on animals.

Though numbers of observers have contributed to the literature of the pathogenesis of the living colon bacillus, since Kiessling's summary was written, the journals within our reach do not show anything having any significant bearing on the question of its toxin.

In 1898, Vaughan and McClymonds,[9] working on the pathogenic germs in cheese, made some observations on the toxin of the colon bacillus found in green cheese, of which the experiments now to be described are really a continuation.

Our own work, so far as we have carried it, has been briefly as follows:

EXPERIMENTS, SERIES 1, FEBRUARY AND MARCH, 1900.

The germ used in these experiments was obtained from a sample of drinking water which was supposed to have caused typhoid fever. It gives the typical colon reactions. One c.c. of a twenty-four hour bouillon culture kills guinea-pigs of 300 to 400 grams weight, within twelve hours, with the usual post-mortem appearances.

On January 31, 17 Roux flasks were inoculated. The growth was removed on February 28, with sterile water and a platinum wire. Centrifugation failed to separate the germs. Absolute alcohol was then added and the suspension was boiled in a beaker and allowed to stand for twenty-four hours, and the germ mass was then collected on a filter. The filtrate was evaporated on a water-bath to a small volume and injected into the abdominal cavity of a guinea-pig without effect. The form of the bacilli was not visibly—microscopically—affected by these manipulations, and they stained readily. The germ mass was then rubbed up in an agate mortar and dried to constant weight in a box water-bath. The dried germ still retained its form and staining properties. One hundred mg. of this dried mass, emulsified with water by boiling, and cooled, killed a guinea-pig on injection into the abdominal cavity, within twelve hours. Section showed the greater part of the germ mass lying in the cavity unchanged and the germs still unaltered in form. Boiling with .25 per cent. potassium hydrate solution does not extract any poison from 100 mg. of the dried germ, nor lessen the toxic effect of the dried germ itself, nor does heating in the autoclave at 130 to 140 degrees, for one-half hour.

Heating in a sealed tube, with water to 184 degrees for one-half hour, forms a milky emulsion which, on microscopic examination, shows granular material with a few unbroken cells. Injection of an amount of this emulsion corresponding to 100 mg. of dried germ into the abdominal cavity of a guinea-pig causes death with the same symptoms as before heating. When the germ mass is separated from the fluid by the centrifuge, both fluid and sediment cause death in the guinea-pig, with the irritant symptoms slight in both cases, but more marked in that of the fluid. Boiling with .2 per cent. HCl and neutralizing has no apparent effect on the toxin.

Two hundred mg. of the dried germ were subjected to forty-eight hours' artificial gastric digestion with a pepsin which was shown by control to be active. At the end of this time the supernatant fluid was poured off from the undissolved portion and an attempt was made to neutralize, but by mistake too much alkali was added. This fluid proved fatal when injected into a guinea-pig, but the symptoms were those of alkali poisoning rather than of the poisoning by the toxin of the germ. The undissolved portion, which proved to be partially soluble on the addition of more water, was fatal when injected in suspension in water—after boiling—while the small amount dissolved in 5 c.c. of water was not fatal, though the animal was markedly affected. In the guinea-pig killed by the suspension, a mass of the undissolved substance was found in the abdominal cavity on post-mortem examination.

The bacterial powder used in this series of tests gives the xanthoproteic and biuret reactions beautifully.

EXPERIMENTS, SERIES 2, APRIL AND MAY, 1900.

For this series a culture of the same bacillus used in the first was taken, but it was rendered more virulent by passing through rabbits until 3 c.c. of a twenty-four-hour bouillon culture killed a large rabbit in one and one-quarter hours.

Sixty moist chambers of 2 per cent. agar were planted with this bacillus, and left for a month at a temperature of about 25 to 30 degrees, and at the end of this time the growth was removed from the greater number and subjected to artificial digestion in an incubator. At the end of three days there was no separation into layers, but there was a cloudy fluid which could not be separated by the centrifuge. At the end of five days there was a separation into a deposit covered by a brownish opalescent fluid, colored probably by the coloring matter from the agar, and apparently free from suspended matter. A drop dried and stained showed only amorphous substances. A flocculent precipitate was slowly formed on dropping into absolute alcohol. The fluid gave the biuret, xanthoproteic and Adamkiewicz tests, and became less cloudy on neutralization with sodium bicarbonate. Ammonium sulphate gave a flocculent precipitate after neutralization. The germ mass was treated with four volumes of absolute alcohol, filtered, washed with absolute alcohol, and the residue on the filter scraped off, dried, and rubbed to a powder in an agate mortar. This powder is rather dark in color and amorphous. It is almost entirely soluble in water and more readily so on the addition of a small quantity of $NaHCO_3$. When boiled with water, cooled and injected into guinea-pigs, it is uniformly poisonous in doses from 4 mg., the largest, to 5/16 mg., the smallest, tried. There is little variation in the symptoms or the time required for killing with these various doses, the pig which received 5/16 dying within twelve hours as well as the one that received 4 mg. All the pigs showed marked symptoms shortly after inoculation, often falling within a few minutes and exhibiting some convulsive movements, but rising again and sitting motionless until a few hours later spasmodic movements of the legs began, then shortly they fell on their sides and remained there, continuing the spasmodic motions until shortly before death.

The bacterial powder used in this series of experiments also gave the biuret and xanthoproteic reactions.

These investigations need to be supplemented by a number of others regarding both the toxic action and the chemical nature of the substance we have obtained; and we hope later to be able to carry on similar investigations in regard to other species of bacteria—in fact, we have already begun a study of the bacillus of anthrax. We believe, however, that we are able to draw with some degree of certainty a few conclusions from what we have done already. These are as follows: 1. The colon bacillus in virulent form contains within the cell a toxin which is fatal to guinea-pigs of from 200 to 300 grams weight, in quantities of less than 1 mg. 2. The aqueous extract of the cells of the colon bacillus grown on agar is inert. 3. The entire germ is highly resistant to heat and to dilute acids and alkalis. 4. The cell wall of the colon bacillus is digested by the prolonged action of artificial gastric juice, which does not alter the toxin. 5. The toxin as thus obtained is insoluble, or but slightly soluble, in dilute acid, but is slightly soluble in water and more readily in dilute alkalis. 6. This toxin responds to the ordinary proteid reactions. 7. The toxin, after being freed from the cell membrane, is not destroyed by being boiled. We will endeavor by further research to determine more definitely the nature of this toxin and will extend our investigations to other bacteria.

THE TRUE ROLE OF DRUGS IN THE MANAGEMENT OF CONSUMPTIVES.*

SOLOMON SOLIS-COHEN, M.D.
PHILADELPHIA.

Tuberculosis is curable, or rather, if we may use the word, it is recoverable. It is never cured by the physician, but by the patient himself; that is to say, by the natural powers of recovery. These however may be, and usually need to be, stimulated, assisted and directed by wise medical guidance. Under favorable surroundings at least three-fourths of those affected with pulmonary tuberculosis should recover. Many recover spontaneously, even under unfavorable conditions.

SECONDARY ROLE OF DRUGS.

In the physician's management of consumptives—that is to say, of persons affected with pulmonary tuberculosis—drugs play a useful, but a secondary part. The principal means of treatment for the relief or recovery of these patients are included under the general term of hygienic measures; that is to say, life in the open air, with abundance of sunlight; properly selected diet and clothing; the use of water freely, both internally and externally; rest and exercise, prescribed carefully and definitely, according to the stage of the disease and the general characteristics of the patient; the use of air at modified pressures, and the like. These bring about a physiologic reinforcement of the patient's recuperative energy, and this conquers the disease.

HYGIENIC MANAGEMENT NOW RECOGNIZED.

When I began writing on the subject of the treatment of pulmonary tuberculosis some fifteen years ago and in most of my communications on the subject since, these measures in whole or in part have been emphasized; and it is with the greatest gratification that I have observed this much neglected but ancient gospel, emphatically preached by Rush, in America, and Beddoes, in England, more than one hundred years ago, by Sydenham and others much earlier, and of which I have been an humble modern apostle, at last beginning to make itself felt, not alone in medical literature, but in contemporary practice.

THE OCCASION FOR DRUGS.

I may be pardoned, therefore, if on this occasion I speak of the use of drugs, of what may be accomplished with their aid, and of what it is useless to expect from them. Both in the general course of the disease—whether in its development toward destruction or in its progress toward recovery—and in the incidents and accidents accompanying this course, occasions arise in which the aid of drugs may usefully be sought to promote comfort, to prolong life, or to assist recovery. It is essential, however, that the physician should know definitely the powers and the limitations of the agents employed; that they should be used with definite purpose; and that their use should be sufficiently persistent while needed, but discontinued when its purpose has been accomplished.

What then are the indications for the use of drugs, and what their limitations? To answer these questions it is necessary to have a clear idea of the nature and progress of the pathologic conditions and processes embraced under the head of pulmonary tuberculosis. This is not the place to enter into detail, but certain broad outlines may be noted.

DEVELOPMENT AND PROGRESS OF PULMONARY TUBERCULOSIS. HYPOTROPHY.

In every instance of pulmonary consumption we have to deal with three distinct stages—with a fundamental or primary *(trophic)* stage, and with secondary *(bacillary)* and tertiary *(micrococcal)* stages of epiphenomena. The fundamental stage is a condition of lessened vital energy, lowered resistance, or malnutrition, which is not a mere vague "susceptibility," but a definite morbid state. For this, lacking a better term, we can adopt that proposed by Jaccoud, namely, "hypotrophy." I have elsewhere suggested the term "abionergy," but this involves a hypothesis not accepted by the profession or by science in general, and need not be insisted on. By whatever name we may term this state, it is not merely *a general depression of function*, but is accompanied with structural changes. In their intimate nature these escape our present methods of research, being probably molecular, and possibly located in the cell nuclei. When the hypotrophic status is inherited, or when it is congenital although not inherited, or when it has been acquired early in life, certain gross structural changes can sometimes be made out. Among these are especially to be noted relative deficiencies in the size of the heart and vessels and certain changes in the shape of the chest and in the physiognomy, to which attention has elsewhere been directed.[1] When it is acquired later in life these gross structural changes are not manifest.

It is in this stage that the recognition of the disease is of the highest importance and that hygienic treatment as well as roborant medication may succeed in averting the succeeding stages of destruction; but unfortunately there are no positive criteria by which it can be infallibly recognized. We can suspect, and the experienced observer can be nearly sure, that he has before him a subject of hypotrophy, but it can not be proved. The early recognition of the early tuberculization of the patient is less difficult.

SECOND OR BACILLARY STAGE. TUBERCULOSIS.

The second or bacillary stage follows the invasion of the bacillus of Koch, and is characterized by the definite histological changes giving rise to the term

---

* Presented to the Section on Materia Medica, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

[1] *Consult* my article on "Tuberculosis," in Vol. i, of Hare's "System of Therapeutics," Phila., 1891, pp. 724, et seq.

"tuberculosis," and by an accompanying toxemia, of which the principal symptoms are irregular fever, cough, digestive disturbance, some degree of anemia and progressive loss of strength and flesh. The physical signs are now definite; slight percussion change, impairment or exaggeration of resonance with heightening of pitch, progresses to dulness perhaps just below one apex; the respiratory murmur progressively changes toward the bronchial type, cogwheel respiration being often the earliest sign; and there is progressive development, darkening and spreading of fluoroscopic shadows. Anemia of the pharyngeal and laryngeal mucous membranes is often to be observed. Sometimes the earliest overt manifestation is hemorrhage, a fortunate circumstance usually, as it leads to the prompt institution of treatment, and thus often to recovery. Cough is not infrequently absent. In this bacillary stage we have then as functional pathology, impairment of respiratory power, impairment of circulatory power, further failure of nutrition, further bacillary invasion, toxemia.

THIRD OR MICROCOCCAL STAGE. PHTHISIS. CONSUMPTION.

The third and most dangerous stage follows the invasion of various bacteria, principally belonging to the tribes of streptococci and staphylococci, for which the ground has been prepared by the destructive changes (caseation, etc.) of the preceding group of epiphenomena; those, namely, dependent on the invasion of the tubercle bacillus. Further destruction and further toxemia with hectic fever and increased emaciation, perhaps frequent hemorrhages, greater cough, progressive feebleness, sleeplessness, night sweats, diarrhea, dropsy, and the like, together with recurrent attacks of lobar and lobular pneumonia and other complications, local and general, mark the progress of phthisis toward death.

Histologically we speak of the secondary epiphenomena as the stage of infiltration; of the tertiary epiphenomena as the stage of softening or cavity-formation. Both processes may be present in different degree and extent in the same lung or in two lungs of same patient.

ACUTE AND RECURRENT TUBERCULOUS BRONCHO-PNEUMONIA.

I have excluded from consideration acute disseminated or miliary tuberculosis, of which the pulmonary phenomena are but part of a general process, from which recovery is at least doubtful. Attention must be called, however, to the group of cases of acute tuberculous bronchopneumonia, in which the secondary and tertiary groups of epiphenomena can not strictly be separated, occurring either coincidently or with but slight interval. Then, too, there is a group of cases in which destructive tertiary phenomena occur early, but in limited areas, and with but slight tendency to extension. The progress of the case is frequently interrupted by remissions or even by intermission of long duration.

COMPLEXITY OF SEMEIOLOGY.

Thus a varied and apparently contradictory semeiology arises, but analysis will always show that in some portion of the lung the secondary or tertiary phenomena predominate, and that the general symptoms depend partly on the local conditions, and partly on the predominant toxemia. There are thus minor stages or phases within the major stages.

NECESSITY FOR INDIVIDUALIZATION.

Quite obviously the treatment applicable at a given stage or phase of these complex processes differs from that applicable at any other stage, preceding or succeeding. Moreover, individual patients present great differences in their response to hygienic measures, these differences being dependent on the same constitutional powers or weaknesses that have enabled them to resist, or have made them succumb to some or all of the morbid influences. Thus each case becomes an individual study, and so continues throughout its different phases, and whatever is said concerning the general management of patients at various stages of the disease is to be understood as being thus qualified.

NO SPECIFIC.

We are now prepared to discuss the use of drugs. In the first place, it must be evident that no specific against the exciting causes of the disease or against any of the morbid processes is to be looked for. As the hygienic management of consumptives is designed to build up their vital resistance, so the auxiliary medication must have this for its primary object, incidentally combating special morbid phenomena or groups of phenomena which of themselves introduce special dangers. While I can not go so far as my friend, Dr. Mays, in looking on consumption as a neurosis, there is little doubt that among the failures of nutrition, which prepare the ground for tuberculosis, the nervous system is involved.

NERVINES.

Drugs useful from this standpoint are arsenic, strychnin, cod-liver oil, hypophosphites and other preparations of phosphorus, among which are probably to be included the nuclein group and thymus-gland extract. Strychnin should be given at first in small doses, and according to circumstances may sometimes be increased to very large doses, though only for limited periods. Its use should not be continued indefinitely, as this tends to exhaust nervous structure and nervous energy. Cod-liver oil is a fatty food and seems to have some special suitability to the needs of the nervous structures for aliment. Whether arsenic affects the nerves directly or indirectly through its action on the blood and other tissues, I do not know; but it is to be placed in the first rank as a nerve tonic. These agents are useful in the primary stage, before the invasion of the bacillus, and in the early stages of bacillary action. Their usefulness is less apparent in the later stages, though if recession of morbid phenomena takes place in these stages they may again be used.

DIGESTANTS.

Agents to improve digestion are useful from the standpoint of general nutrition. These do not differ in principle, in method of application, or in character, from the agents used for similar purposes in other affections. Strychnin and arsenic again have application; while lavage or the drinking of hot water and the use of gastric and intestinal antiseptics, sedatives and stimulants; of phosphoric, hydrochloric and nitric acids; of digestive ferments, pepsin, pancreatin, diastase, papain and the like, must be guided by the special symptoms and responses of the individual case.

HEMATINICS.

As a rule there is very little positive anemia in the early stages of tuberculosis, but the same group of hematinic agents that are used in other anemias are applicable here. Thus again arsenic is of service; and iron, gold and sodium chlorid, palladium chlorid, the nucleins, bone-marrow and the like also prove useful.

ELIMINANTS.

It is necessary that the skin should be kept in good condition and that all the eliminative functions should be properly performed. The daily bathing and sponging tends to keep up the tone of the peripheral vessels and of the skin, while diuretics and laxatives, of which spartein and cascara may be taken as types, are employed from time to time if indicated.

AGENTS ACTING ON THE CIRCULATION.

The condition of the circulation needs separate study, and more specially in the primary stage and in the acute manifestations of the tertiary stage. I desire therefore to call special attention to the usefulness of nitroglycerin in the early stages and of digitalis in the acute processes of the tertiary stage.

Nitroglycerin by its action in relaxing the peripheral vessels both in the systemic and pulmonary circulations, permits the work of the heart to be performed better and with less expenditure of vital energy. Vascular insufficiency is, as we have already noted, one of the characteristics of congenital hypotrophy, and the absence of blood-channels from the histological tubercle is not without significance in this connection. One of the greatest advantages of the use of the inhalation of compressed air with expiration into rarefied air, as well as one of the chief factors in the altitude cure of pulmonary tuberculosis, is the increased distribution of blood and nutrient lymph into the ultimate vascular channels and pericellular spaces. Even without the inhalation of compressed air, nitroglycerin aids such dissemination of reconstructive pabulum, as well as the better collection and excretion of waste which accompanies the improved ultimate circulation.

Digitalis was especially commended by Beddoes as the result of his empiric observation, in cases of galloping consumption, with high fever and rapid pulse, and he reported striking instances of the benefit following its use. I have no rational explanation to offer of this action, unless the inhibition of the heart may account for it, but empirically I can confirm Beddoes' observation. I have frequently seen remarkable reduction of fever and the accompanying group of hectic phenomena follow the use of large doses of digitalis, both in the late stages of chronic pulmonary tuberculosis and in the recurring acute attacks of tuberculous bronchopneumonia, or of lobar pneumonia in tuberculous patients. It must, however, be given continuously and fearlessly, up to the point of tolerance, the only counterindication being evidences of untoward effect on the stomach. Merck's German digitalin may then be used in its place; the dose being from 1/24 to 1/8 of a grain, or even more, thrice daily.

IODIN GROUP.

Of drugs used to combat more or less directly the local and hemic results of bacillary invasion, two groups of agents have stood the test of time—the iodin group and the creosote group. The first is applicable especially in the early stages of pulmonary infiltration; the latter, when destructive changes belonging to the bacillary phenomena have begun, and also when the pyemia and increased destruction of the tertiary processes are manifest. The most useful of the iodin group is iodoform, which must be given in comparatively large doses and over large periods. The dose, however, is to be small at the beginning and to be increased very gradually to the point of tolerance. If there is any disease whatever in which it is a mistake to look for results quickly or to be in a hurry to make changes in the administration of drugs, it is the one under consideration. Chronic cases require chronic, that is to say, persistent treatment, and the organism must often be accustomed gradually to the remedy. Beginning with ½ grain of iodoform three times daily, after meals, the dose may be increased, little by little, until in the course of two or three months it reaches 5 grains, three times daily. Balsam of Peru is an excellent excipient and the addition of a digestive ferment sometimes enables it to be borne by stomachs otherwise intolerant. Iodoform may usefully be combined with iron, with arsenic, with strychnin, and with digitalis, in cases in which these latter drugs seem indicated.

A favorite formula of my own in the early stages of the bacillary disease is as follows:

℞.	Iodoformi	gr. i-iii
	Strychninæ sulphatis	gr. 1/40
	Arsenii iodidi	gr. 1/12
	Balsami Peruvianæ	gr. ii-v

Mix and encapsulate. Dose: one capsule after meals three times daily.

Sometimes ichthyol is used as the excipient, with or without the Peruvian balsam. Ichthyol has itself been recommended as of use in pulmonary tuberculosis, in doses of 5 grains or more, thrice daily. Crude or refined petroleum may be used similarly.

Flick, of Philadelphia, a careful observer and accurate reporter, states that he has seen much benefit from the inunction of iodoform in cod-liver oil or lanolin. Lately he has substituted europhen for the iodoform, on account of the disagreeable odor of the latter. For the benefit of those who prefer to use iodoform in this way, I would state that attar of rose in very minute proportion will successfully mask the odor. My own experience with the inunction method is slight, and it did not seem to possess any special advantage over the administration of the drug by the mouth. Iodoform dissolved in sterilized olive-oil, in the proportion of 1 to 10, may be given likewise by intratracheal injection, in quantities not exceeding ½ dram.

Powdered iodoform may be insufflated into the larynx, or iodoform dissolved in ether—1 to 10—be applied by sponge, especially in cases of tuberculous laryngitis, after the application of lactic acid or formalin, and the dose need not be measured especially. There is no objection to covering the entire area of laryngeal and perilaryngeal tissues accessible, and doubtless some good effect is due to systemic absorption as well as to the local action. Other iodin preparations are Lugol's solution, compound tincture of iodin, arsenic iodid, iron iodid, and metallic iodin encapsulated with some fatty or mucilaginous vehicle or emulsionized with cod-liver oil; all of which may be used under special conditions not necessary to detail here.

CREOSOTE GROUP.

The creosote group is large and contains a number of useful agents—carbolic acid, creosote, guaiacol, and combinations of creosote and guaiacol. I have not used carbolic acid for internal administration, though it may sometimes be usefully employed locally, in proper dilution, and has been given hypodermically in sterilized olive-oil, in strength of from 1 to 10 per cent., and in doses of from 1 grain to 10 grains. The urine must be carefully watched when carbolic acid or creosote is used in this way. Beechwood creosote is a sufficiently good prepartion, provided a pure article can be obtained. Much of the commercial creosote contains impurities that irritate the stomach and the kidneys, but there are at least two good preparations in the market, and if care be exercised to obtain one of these the drug can be given in very large doses without untoward effect. Beginning with ½ minim three times daily, it is my custom to increase cautiously up to the point of tolerance, maintaining at that point or decreasing, according to the results in the individual case. I have given as much as 40 minims three times daily. An average dose is 10 minims three or four times daily. It may be given in milk, in which case two hours after meals is a very good time for its administration, as thereby the patient is induced to drink a glass of milk at that time. It may be shaken up with cod-liver oil and taken immediately after meals, or it may be made a part of a compound emulsion of cod-liver-oil. It should not be given in capsule unless associated with at least 5 minims of an oily vehicle to each minim of creosote. Capsules may thus be prepared with morrhuol or cod-liver oil as excipient. When creosote can not be taken by the stomach in sufficiently large doses, it may be given emulsionized with cod-liver oil or milk, by the rectum, and some have given it in sterilized olive-oil hypodermically. Creosote carbonate, commercially known as creosotal, is perhaps the best form in which to give creosote, as it rarely upsets digestion, the taste is not objected to, and in many cases it can be given in dram doses without untoward effect. Such doses may be persisted in for prolonged periods. I frequently give it in hot milk two hours after meals, though it may be given in water or without vehicle, if taken at meal time. The objection to it is its high cost. Recently creosote valerianate and other creosote combinations have been brought forward and are said to possess advantages over those mentioned. I have had as yet too little experience to speak positively concerning this.

Guaiacol, to which some attribute all the good effects of creosote, may be given in the liquid form, just as creosote is given; or its salts, which are tasteless powders, may be substituted. Of these, I prefer on the whole guaiacol carbonate, though in certain cases the benzoate and the salicylate seem to have advantages; the benzoate especially when there is a tendency to diminution of urine and the salicylate when high fever is a marked symptom. The dose is 10 to 60 grains daily, 20 grains being an average dose. Guaiacol potassium sulphonate is a recent addition to the list of combinations and is highly lauded by some writers. The objection to the guaiacol salts also is their cost. Their great advantage is the readiness with which they can be administered, and their lack of untoward local effect. Liquid guaiacol sometimes has seemed to be useful as an analgesic and antiphlogistic application topically in cases of laryngeal infiltration. As its pain-relieving effect is preceded by intense burning, the latter should be guarded against by a preliminary application of cocain, as in the case of other local agents. It is a useful ingredient in external applications to relieve pain; and slowly rubbed in drop by drop, in doses of 20 to 40 drops, the site of application being then covered with cotton and oiled silk, it may serve as a temporary expedient to reduce high temperature otherwise uncontrollable. One must guard against chill following this method.

BALSAMICS AND TEREBINTHINATES.

Another group of drugs useful in controlling morbid conditions, especially catarrhal processes, in the lungs and bronchi, in relieving cough, and in correcting the character of the expectorated matters, is formed by the balsamics and terebinthinates. Of these I would call special attention to myrtol, which may be given in doses of from 5 to 10 minims, dropped on sugar, encapsulated, or emulsionized, just as one would give turpentine, terebene, eucalyptol, or other agent of this group. For the production of results, its use must be persisted in for several weeks at least. Ichthyol also may be given internally in capsule, alone or combined with some of the drugs already mentioned, and seems to have especially good effect in the correction of collateral fetid bronchitis.

For the correction of local conditions in the throat, trachea, and bronchial passages, and in combating the septic processes of the tertiary stage, so much more destructive than tuberculosis in itself, as well as for sedative effect, drugs may be employed by inhalation or by intratracheal injection.

INHALANTS.

For inhalation, myrtol, eucalyptol, thymol, menthol, oil of peppermint, camphor, chloroform, bromoform, creosote, formaldehyde, and ethyl iodid may be used singly or variously combined. The little perforated zinc respirator, designed by Dr. Burney Yeo, is an extremely useful appliance for this purpose, and for continuous respiration by its aid combinations like the following may be used: chloroform, eucalyptol, creosote, alcohol, equal parts; myrtol, chloroform, terebene, equal parts, etc.

ETHYL IODID AND FORMALDEHYDE.

Among these drugs, however, I desire especially to signalize two, ethyl iodid and formaldehyde. The former may be used very simply by merely unstoppering the amber-colored, little-necked, ounce vial in which it should be kept. The heat of the hand is sufficient to volatilize the medicament. The vial may be held to the mouth or nostrils and deep breaths taken for from one to five minutes, according to the effect. This may be repeated as necessary; in cases of irritative cough, as often as every half hour. It is especially useful in cases of laryngeal tuberculosis. I have experimented in various ways to obtain formaldehyde in proper shape for inhalation. The little lamp, by means of which paraform is converted into formaldehyde gas, has seemed on the whole the best. This is allowed to impregnate the air of the room in which the patient remains, menthol or eucalyptol being sometimes volatilized concurrently; or, covering his eyes, the patient sits by the lamp and every now and then gathers in his incurvated palm some of the gas diluted with atmospheric air and inhales that; or paraform tablets may be crushed in the hand, and the endeavor made to get a certain amount of diluted gas from this. Or in a simple wash-bottle inhaler of 12-ounces capacity a solution of formaldehyde in water may be added to glycerin and aromatics, the whole mixture making about 3 ounces. The strength of the formaldehyde solution is from 1 per cent. to 2 or 3 or even 5 per cent., as the patient bears it. None of these methods, and no other method that I have employed, is entirely satisfactory. If formaldehyde gas, properly diluted, could be collected in a reservoir and from this inhaled, as oxygen, nitrous oxid, and the like are inhaled, it would undoubtedly be useful.

PALLIATION OF FEVER.

In the course of the disease, whether toward recovery or death, there are a number of special symptoms and symptom-groups developed, for which palliative measures may be employed. Some of these may be referred to briefly. Fever, that is to say, temperature persisting at, or persistently recurring to, 100 F., or more, needs palliation, preferably by rest and the application of an ice-bag over the heart. And I may here interpolate that a long sea-voyage is the best possible treatment for patients exhibiting this tendency. The coal-tar products may be used cautiously if necessary to give the patient comfort; they are not curative of the conditions—the intoxication—causing the fever. Much better in many cases is the inhalation of nitrous oxid in the forenoon—i. e., before the expected rise of temperature—usually in two sittings, two hours apart; about 8 gallons mixed with atmospheric air, at each sitting. The mixture is obtained by inhaling pure nitrous oxid through the mouth, the nose being left uncovered. The ordinary cylinder and wash-bottle form the preferable apparatus. Oxygen inhalations are counterindicated.

TREATMENT OF HEMORRHAGE.

Hemorrhage, an alarming accident to the patient, the family and the inexperienced physician, will subside spontaneously in nine cases out of ten, if the patient be put at rest. Cold applications are generally useful, an ice-bag being applied over the heart, or over the seat of bleeding, if that can be located without undue disturbance to the patient. Cold food only is to be given, and in small quantities. Use of the voice is to be interdicted, and laxatives should be given to prevent straining at stool. When necessary, the force of the heart's action can be reduced by aconite in appropriate doses, and cough be checked by opium, codein, or morphin. It is possible that heroin may serve better than the natural morphin. In severe cases, morphin may be given hypodermically up to the point of tolerance. The most generally useful drug to promote coagulation of blood and the formation of permanent clot, sealing the wound in the vessel or vessels, is crystallized calcium chlorid. With this, codein, turpentine, or thymus extract may be associated. The calcium salt is to be given in dilute solution in comparatively large doses, say 15 grains every second hour; for not more than four days consecutively. If medication is still necessary, lead acetate may then be given—say 3 or 5 grains in pill with an equal quantity of tannic acid and perhaps a grain of opium, three or four times daily. After two or three days, aromatic sulphuric acid should then be given, after which, if necessary, the calcium salt may be resumed. Ergot is useless in most cases. Atropin sulphate, say 1/120 grain, given hypodermically at the beginning of hemorrhage will often cut it short. Hydrastinin hydrochlorate is among the useful astringents.

NIGHT-SWEATING.

For night-sweating, agaracin, hyoscin hydrobromate, potassium tellurate, camphoric acid, atropin, strychnin, picrotoxin, and the like, are useful internally, while sponging with alcohol and alum, or with an alcoholic solution of quinin, or dusting with zinc oxid or zinc oleostearate will sometimes render internal medication unnecessary.

DIARRHEA.

Diarrhea is often exceedingly troublesome and not to be controlled by regulation of diet. Among the drugs useful in different cases are arsenic, mercuric chlorid, cupric sulphate, iron sulphate, tincture of ferric chlorid, opium, tannic and gallic acids, bismuth salicylate, benzonaphthol, salol, guaiacol salts, etc. Before using either astringents or opium, the bowel should be thoroughly washed out by the administration of calomel in small doses, followed by a saline laxative, and this by irrigation with hot—physiologic—saline solution. Notwithstanding, however, the combined use of astringents, opiates and antiseptics, this symptom proves rebellious in many cases.

CONCLUSION.

The object of this paper, however, has not been to go into details of treatment or to advocate the use of any special agent in any special condition; above all, not to seem to prefer drugs to the hygienic and nutritional measures already sufficiently alluded to, and of which may again be specified open-air life with abundance of sunlight, as the most important of all. I have wished simply to indicate for what purposes drugs may wisely be employed, and to suggest different groups of agents applicable for these purposes, from which choice is to be made according to all the circumstances of the particular patient, time and place. Bearing in mind the limitations of drugs as well as their powers, and carefully selecting them for definite purposes, they may thus be made to fulfil their useful, but secondary part in the treatment of patients having pulmonary tuberculosis.

THE IMPORTANCE OF AN EARLY DIAGNOSIS OF TUBERCULOSIS.*

A. MANSFIELD HOLMES, A.M., M.D.
DENVER, COLO.

The failure to recognize tuberculosis in its incipiency is the result of several causes: Tuberculosis has an insidious beginning. Most patients do not recognize the nature of their trouble until a lesion is well established, and frequently when they consult a physician the disease is well advanced. The symptoms which belong to the incipient stage are not easy of recognition and are frequently misinterpreted by the examining physician. Many patients will not accept the facts until it is too late. Many physicians fail to give the facts at this stage for fear of frightening patients.

These are the principal reasons why tuberculosis is frequently unrecognized until it is too late to hope for relief; and, also, furnish an explanation for the widespread belief that tuberculosis is incurable.

Before beginning to discuss the subject of the early recognition of tuberculosis it seems essential that some definite method of classification should be understood. Almost as many methods of subdividing the disease have been considered as there are those who have given the subject special study. There seem to be few distinct lines of demarcation which serve in making a subdivision that is without criticism. The pretubercular state, the early stage, and the advanced stage are terms which are frequently used; but these terms convey very little definite information, unless they are qualified by a more minute description.

This subject, however, is of too serious import to justify the useless discussion of mere technicalities. The classification which I shall adopt in this discussion rests upon a histological basis, supplemented by the bacteriological principle that a congenial culture-medium is essential for the growth of pathogenic germs. This classification will admit of three fundamental stages:

1. *Pretubercular Stage.*—This stage is accompanied by a diminished resisting power. We have an impairment of function without a change in the structure of the tissues. The tissues are reduced to a more or less weakened state and furnish a congenial soil for the development of bacilli; but the bacilli have as yet not gained an entrance into the tissues and commenced active development.

2 *Stage of Tubercle Formation, or of Constructive Tissue Changes.*—This stage begins with the introduction of bacilli into the weakened tissues and is known as

---

* Presented to the Section on Materia Medica, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

early incipiency. We have rapid cell-proliferation and the formation of tubercles or small neoplasms. We have a transformation of tissue without disintegration, accompanied by a further impairment of function. This stage extends to the beginning of tissue disintegration.

3. *Stage of Destructive Tissue Changes.*—We have softening and breaking down of tissue or fibroid transformation and atrophy of tissue, with more or less complete loss of function.

Nature of Tuberculosis.—Many views have been entertained as to the nature of tuberculosis, and may be arranged into three groups: that bacilli constitute the sole factor of tuberculosis; that the soil is the sole factor and that bacilli play a secondary part; the dual theory that the germ and the congenial soil are equally responsiple factors.

It is foreign to our purpose to discuss the merits of these views. Let it suffice to say that the dual theory is accepted as the basis of the remarks which are to follow.

THE PRETUBERCULAR OR PREPARATORY STATE.

The conception of the dual nature of tuberculosis renders a pretubercular or preparatory state indispensable. This brings us to the nature of the resisting power of an organism and the methods by which this resistance is reduced.

It is a well-conceded point that the resisting power to disease is measured by protective substances which are elaborated by the organism itself. These substances are believed to be the products of cell-metabolism and are known as antitoxins. When the changes are brought about in an organism which diminish the production of this protective material, the natural defense of the organism is thereby weakened and invading germs meet with little resistance.

Since the resisting power of an organism can be traced ultimately to but one source—the cellular elements of the organism—a strong resisting power is the manifestation either of a strong phagocytic power, or of a strong antitoxic power, or of both combined. Furthermore, since antitoxins are the metabolic products of the body-cells, a potent antitoxin presupposes vigorous cells; and inversely, if the potency of the antitoxins is feeble, it presupposes a feeble cell-activity. Hence, if the vital forces of the body-cells of an organism are too feeble to produce antitoxins of standard potency to protect it against a certain species of germs—which normal organisms of the same species are able to resist—its resisting power is impaired.

On the other hand, if it should be claimed that the resistance to tuberculosis depends on a vigorous phagocytosis, a strong resistance to the disease presupposes vigorous body-cells; and inversely, a feeble resistance presupposes weak and poorly nourished body-cells.

With this explanation of the pretubercular state we have a rational hypothesis on which we can rest. It furnishes an explanation why persons in this state readily develop tuberculosis, and offers an argument why we should strive to recognize this condition.

The pretubercular state, therefore, may be defined as the condition of feeble activity of the body-functions, producing in consequence a diminished potency of the protective substances of the organism, thereby furnishing a fertile soil for the development of the bacilli of tuberculosis.

The influences which aid in the development of tuberculosis are of two varieties: predisposing factors, and exciting factors. The first variety comes with a bad family history. Persons possessing these factors may be recognized as possessing the following characteristics: a frail organism with feeble functions; narrow chest; drooping shoulders; diminished chest expansion; weak nutritive processes and feeble powers of endurance. The existence of these predisposing factors is evidence of a weak resistance to disease and often may be recognized early in life. To those familiar with the early signs of tuberculosis the significance of these factors needs no comment. To the predisposing factors we must add a class of exciting factors. These are the influences which tend to diminish the already weakened resistance of the individual. To a great degree these factors are under the control of the individual. Examples of this class are insanitary surroundings; sedentary or irregular habits; dissipation; indoor occupation; prolonged overwork; and serious illness. Few persons can withstand the prolonged action of these exciting factors without yielding their resisting power. Especially is this true of individuals who have inherited a weak resistance. Sooner or later opportunity for infection will be presented and persons with a weak inheritance will imperceptibly and unconsciously pass from the pretubercular state into the stage of actual tubercle formation.

The duration of the pretubercular or preparatory state varies according to the degree of the impaired resistance of the individual and the nature of the existing factors. An early recognition of the pretubercular condition as described, and an early attempt to correct it, may enable the individual to recuperate his forces before bacilli gain a lodging in his tissues. Many a person may thus, by judicious care, prevent the actual development of tuberculosis, although there may be a strong predisposition, and ultimately he may die of some other disease. Unfortunately, however, much time is frequently allowed to elapse; the unfavorable influences are allowed to continue; the patient refuses to heed the signals of alarm, and before he is aware of his condition, active incipient tuberculosis is established.

THE STAGE OF TUBERCLE FORMATION.

This stage dates from the time when tubercle bacilli gain admittance to the weakened tissues and begin active development. The chief object of this paper is to collect and classify the evidence which points to the existence of the incipient stage.

Classification of Evidence.—The total evidence of this most critical period of the patient's history may be classified as follows: 1, family and personal histories; 2, clinical symptoms; 3, physical signs; 4, microscopical evidence—blood and sputum; 5, X-ray evidence; 6, tuberculin test.

The early evidences are by no means uniform in the order of their development. The evidences most frequently observed and significant of approaching danger, if properly interpreted, are the following: Impaired nutrition, loss of appetite, gastric and intestinal disturbances, accompanied by loss of weight and strength: dyspnea and fatigue after light exercise, accompanied by small, rapid and variable pulse; slight but persistent cough in mornings and on deep inspiration; impoverished blood state; hectic flush, hemorrhage, altered or suspended menses; sore throat, hoarseness and aphonia; pleurisy pains; glistening eye, dilated pupils, leaden hue of the sclera; insomnia, night sweats; subnormal morning temperature and afternoon or evening fever.

The Value of Early Evidence.—As to the importance to be attached to the early symptoms of tuberculosis it is well known that many erroneous opinions prevail. In this connection it might not be amiss to note a few points, although on account of limited space many valuable points must be left unnoticed.

Chief among the misinterpretations of diagnostic evidence is the altogether too-prevalent opinion that the presence of tubercle bacilli in the sputum is one of the earliest manifestations of the disease. During the period of tubercle formation bacilli are located in the deeper tissues of the body. During this period bacilli rarely make their appearance in the sputum, notwithstanding patients are already suffering from tuberculosis. When bacilli are found in the sputum it is evidence that the disease is well established; while if bacilli are not found, their absence is not sufficient evidence to exclude tuberculosis. Therefore, for diagnostic purposes in the early stages of tuberculosis I am of the opinion that we overestimate the importance of the examination of the sputum.

A series of clinical symptoms invariably precedes the breaking down of tubercles and the appearance of expectoration containing bacilli. For the purpose of making an early diagnosis it is therefore of special importance that we should be able to recognize and properly interpret these early symptoms.

The cogwheel respiration has for some time impressed me with its diagnostic value of early areas of pulmonary infiltration. This, to my mind, is underestimated as an early symptom of pulmonary tuberculosis. This phenomenon is frequently observed when no other stethoscopic evidence of the disease can be detected, and subsequently other symptoms of tuberculosis develop. I have observed this phenomenon more distinctly during the latter part of forced inspiration and also find it synchronous with each cardiac systole. The areas over which it is elicited are local and circumscribed. It seems to be increased with the force of the heart and therefore is more distinct after light exercise.

Let us briefly consider the factors involved in the production of this symptom. During forced inspiration the entire available lung space is occupied by air; the lung tissues are compressed and, for the time being, make greater pressure against the pulmonary vessels; this in turn tends to prevent the vessels from expanding under the heart's contraction. Infiltrated tissue possesses diminished elasticity. Therefore the blood-vessels in a circumscribed area of infiltration are unable to enlarge their caliber under the increased blood-pressure accompanying each beat. This diminished compensation of the blood-vessels of the infiltrated tissue necessitates an increase of friction of the blood against the walls of the vessels in these areas; and this increased friction is further increased during inspiration. I would not be understood as believing that this phenomenon is always present or that it is always significant of tuberculosis. I believe, however, that it is evidence of impaired functional activity of small areas of lung tissue. Therefore whenever I recognize this characteristic respiration I suspect areas of diminished resistance and endeavor to keep the patient under close observation for further evidence of tuberculosis.

A rapid and variable pulse is an early symptom of pulmonary tuberculosis of no small significance. This is especially pronounced after moderate exercise. Therefore the recognition of this symptom invariably calls for a careful physical examination of the chest for initial areas of infiltration.

Cough is often the first symptom to attract the attention of the patient. I have, however, frequently seen patients in incipient and well-advanced stages in whom there had been no complaint of cough or chest symptoms.

Pleuritic friction sounds may almost always be considered of tuberculous origin, and are often early symptoms.

Râles do not properly belong to the early stage of tuberculosis. They are frequently present when the area of infection is very limited. But in such patients the diseased area may have existed some considerable time before the tubercles undergo softening; then râles become recognized.

Hemorrhages are often the first symptom of the local disease. Hemorrhages are not always due to a tubercular lesion. They may result from violent exercise, physical injuries or other causes; but a hemorrhage should serve as a warning to a patient that a lesion exists in the lung which offers a fertile soil to tubercle bacilli: and furthermore, while such a condition exists, the patient is in constant danger of becoming infected. Such persons should exercise great precaution to avoid infection and at the same time make use of every possible means to restore the injured tissues to their normal state by appropriate rest and tissue nutrition.

I have found a study of the blood an important factor in revealing impaired metabolism and a low state of the vital functions. For years I have kept records of the blood and sputum in all cases of tuberculosis. A study of these records is evidence that the blood phenomena are of greater service in revealing the actual condition of the patient than those furnished by the sputum. The nature of the study has been a differential estimate of the leucocytes made from a stained film of blood and a study of the morphological appearance of these cells. The limited time alloted to a paper of this nature will not permit of a description of the phenomena presented by tuberculous blood, especially since a description of these phenomena has been attempted in former articles.[1]

A subnormal morning temperature is one of the earliest and I believe most valuable means of revealing the pretubercular and incipient stages of tuberculosis. When persistently present we may be certain of a low vital state. Frequently a subnormal morning temperature is unaccompanied by an afternoon or evening fever. I am inclined to believe that when a subnormal morning temperature persistently continues it points to a pretubercular state, and that the patient is approaching dangerously close to the incipient stage; also, that when it is accompanied by afternoon or evening fever it is strong evidence of actual tubercle formation. It should be remembered that many tuberculous patients do not develop fever, and yet these persons almost invariably have a subnormal morning temperature. It should be noted, however, that before a marked subnormal temperature or any other symptom should be accepted as evidence of tuberculosis it should be supported by other signs of danger.

This suggests the inter-relationship of symptoms. We should bear in mind that though a single symptom is evidence it is not sufficient to confirm a diagnosis. We rarely, if ever, find an important diagnostic symptom of incipient tuberculosis unaccompanied by other important symptoms. The intimate relationship between symptoms is therefore a point not to be overlooked in making a diagnosis. For example, with impaired nutrition, loss of appetite and gastric disturbances loss of weight and strength will follow. Let these symptoms continue and the patient will soon experience fatigue after light exercise, accompanied by a rapid and variable pulse. An impoverished state of the blood is also inevitable. Thus the symptoms will multiply and the resisting power of the patient will imperceptibly diminish; and yet, notwithstanding the accumulation of evidence the patient will rarely acknowledge that he is in danger. He realizes, however, that he is more susceptible to exposure; takes cold more readily; recuperates more slowly. A slight catarrhal condition often remains. The patient continues his occupation and makes no effort to remove the influences which are daily increasing the danger. Up to this point how many patients suspect tuberculosis? How many consult a physician? And if the physician is consulted, how often is tuberculosis overlooked for the grip, bronchitis, or some other less dreaded malady?

---

[1] Medical Record, Sept. 5, 1896, p. 325; March 13, 1897; Journal A. M. A., xxix, 17, p. 828.

The Neglect of the Early Signs of Warning.—Examples are all too numerous where the early signs of warning have been unheeded. Inevitably the symptoms progressively develop and the patient passes from the realm of doubt to one in which the most positive evidence is present. The diagnosis is finally accepted after the disease has made rapid progress; but during this period of delay a large percentage of patients lose their only chance of recovery.

Finally, unless we become familiar with the symptoms which accompany the "pretubercular state"—symptoms which develop during the period which leads up to actual tubercle formation—the most valuable period for treatment is lost. Therefore with each case of suspected tuberculosis an important question is presented. How can doubt be removed and the diagnosis confirmed?

On this point I feel that we are safe in adopting the following rule: When the characteristic symptoms which usually accompany incipient tuberculosis are present and persistently continue and we are unable to account for them from other causes, we are justified in suspecting concealed tuberculosis.

The Tuberculin Test.—After having considered the symptoms, the history, the physical signs and the general appearance of the patient, if doubt remains we have a court of last appeal—the tuberculin test. Until recently we were often obliged to remain in doubt in incipient cases, but since the diagnostic value of tuberculin has been established we have no excuse for delay when the symptoms are sufficiently marked to point to tuberculosis. I wish to record my confidence in this means of settling doubtful cases. The danger of tuberculosis is too great to justify our remaining in doubt when we have a reliable diagnostic agent at our command, and especially so since there is little or no danger when it is properly administered.

I prefer to administer the tuberculin late in the afternoon or evening. If a tubercular lesion exists, the reaction usually comes from six to twelve hours later. As previously stated, I find the subnormal morning temperature quite as significant of tuberculosis as the afternoon fever. Therefore if the tuberculin is administered in the evening and a morning fever follows its use, it is evidence of a reaction and points to a tubercular lesion. If no reaction follows the initial test an interval of a few days is allowed to elapse and a second test is administered, and finally a third.

If the tests are properly administered and no reaction is experienced we may feel safe in excluding tuberculosis. It is well, however, to repeat the test at short intervals if the patient's condition remains unimproved.

The use of tuberculin as a differential agent is a subject with many problems awaiting solution. The nature of the reaction, if any, which may be experienced by persons in the pretubercular state and the dose that will be tolerated before a reaction may be expected, are subjects which should call forth our best efforts and most careful observations.

Treatment.—The essentials of successful treatment are alimentation, medication and environment. Malnutrition is a constant condition in tuberculosis. Poor digestion and non-assimilation are always present to a greater or less degree. Hence, a correction of this condition is one of the first points to be considered in therapy. Overmedication is too frequently practiced. Any treatment which impairs digestion is injurious.

The ability to react to treatment depends upon an early recognition of the disease, the degree of impairment of the nutritive processes, and an early correction of unfavorable environment and modes of life.

A properly-selected climate is essential, but patients must seek it early. The advantages to be gained from climate will depend upon the amount of time spent in the open air and sunshine, the thorough ventilation of the living and sleeping rooms, and the maintenance of a normal state of the digestive functions. In conclusion we may summarize as follows:

1. The fact should be more generally recognized that if the vital forces become impaired from any cause whatever, the resistance to the tubercular infection is diminished and the danger of infection increased. Prolonged overwork, dissipation or exposure weaken an organism. The tissues of such persons constitute a fertile soil for the infecting germs. When the germs are brought in contact with the weakened tissues they find favorable conditions for propagation. This marks the actual beginning of tuberculosis.

2. It should be remembered that an early diagnosis is of supreme importance. If we hope to secure good results we must resort to means of examination which will enable us to detect the disease before it has become firmly established.

3. There are early symptoms which make their appearance long before the stage of expectoration.

4. Expectoration is frequently present for a considerable time before bacilli can be found.

5. The diagnostician who delays for the appearance of bacilli in the sputum fails to diagnose the disease in its incipiency and loses the most valuable period for treatment.

6. When the early symptoms are present and no other cause can be found to account for them, we are justified in suspecting tuberculosis.

7. Before arriving at a definite diagnosis we should consider well the previous history, the general appearance of the patient, and the symptoms. After carefully weighing all that can be secured from such a study we should resort to early and repeated physical examinations of the chest; a bacteriological examination of the sputum, if the disease has advanced to this stage; a microscopical examination of the blood; and if doubt remains we should finally resort to the tuberculin test.

8. After the disease is discovered the fact can not be too strongly emphasized that patients can not remain surrounded by insanitary conditions and regain their health.

9. With the exercise of greater care on the part of both physicians and patients in recognizing the early symptoms of tuberculosis, and a more rational use of means to prevent infection, we may expect fewer cases of tuberculosis and a greater percentage of cures.

205 Jackson Block.

DISCUSSION ON PAPERS OF DRS. SOLIS-COHEN AND HOLMES.

Dr. Wm. H. Thompson, New York City, by invitation, opened the discussion. He said that the subjects for discussion that had been initiated already, by these two papers, were so numerous that the Section might spend not only the rest of the afternoon, but a day or two in going over them. He, therefore, would refer to but one or two points. In the first place, when we speak of tuberculosis, it appears as if we have in mind two almost distinct diseases. The first is uncomplicated tuberculosis, the second is complicated tuberculosis. In the former, the tubercle bacillus is not associated with other bacteria. This condition we do not find in the lungs, but we do find it in serous membranes, the peritoneum, for example. Take a case of general tuberculosis of the peritoneum. He had seen the abdomen opened by surgeons and they had found the peritoneum a mass of tubercles; they had then closed it up, for the patients to die, but to their surprise the patients got well. This is not the course of pulmonary tuberculosis. One reason for this is that we have the infection in a tissue or organ that is never at rest, but twenty or thirty times a minute, it moves in the respiratory act. Just as a sore on the leg, if it were rubbed twenty or thirty times a minute, night and day, it would not get well. So if you have an infection with tuberculosis, the constant movement and irritation sets up an ulcerative process and there is secondary infection with pus organisms. Further, wherever the ulcerated process occurs, there is an opening for additional tubercular infection. There are, therefore, in some parts of the body, simple infections with the tubercle bacilli, but in the lungs there is always compound infection. Another point is that the tubercle bacillus can have no antitoxin, because its duration is not self-limited. In acute pneumonia, on the contrary, you have a condition which passes through its course in a few days and then ceases its activity; not so with the tubercle bacillus, it has an unlimited life. The speaker said that he was the first physician in New York who had a supply of Koch's tuberculin. He never personally had any faith in tuberculin, but had a great deal of faith in diphtheria antitoxin. Diphtheria being a self-limited disease can have an antitoxin, but tuberculosis can not. Professor Loomis, who followed him in hospital service, also had doubts as to the specific effect of tuberculin. An important point in pulmonary tuberculosis is to know the time when infection takes place. You see a man 20 or 30 years of age, with signs of beginning pulmonary tuberculosis. When was he infected? He might have become infected as a child, when he was 1 year old, and the disease for some reason did not find a favorable moment for development until twenty or thirty years had passed. This is now the general view of the pathologist. About two years ago there was a discussion at the Pathological Society of London, published in six numbers of the *British Medical Journal* and *The Lancet*, in which the fact was brought out prominently that there are many cases of infection in childhood, but that it does not develop into pulmonic tuberculosis usually until in adult life. Hirsch, who found in adult autopsies more than 75 per cent. which showed tubercular lesions, is of the opinion that the entrance of the tubercle bacilli into the body is usually with the milk, as in a child. This has been demonstrated over and over again. The tubercle bacillus finds its nidus with the serous membrane, and keeps on doing its specific work, and emaciation and other physical changes finally result. What do we mean by emaciation? It is not a simple loss of fat, but it means a loss of every part of the body, except the nervous system, which never emaciates. The peculiar tubercular facies, or physiognomy has been referred to. He would recognize it at a glance. Every long bone is thin, the muscles of the neck are ribbon-like; every rib is long and thin, the hands and lips are bloodless—therefore, before examining the chest, you recognize that you have to deal with a condition in which there is a deposit of tubercle. That is in an adult, and these changes of development have been brought about because he has been suffering from that very thing since early life. He fully believes that we can do almost nothing against pulmonary tuberculosis. He feeds his patients fresh meat, gives them cod-liver oil for its influence on nutrition, and gives them iodin, arsenic, for the same reason, to improve the nutritive powers. But when he has done that, he asks what he has done with the tubercular infection per se? If the patient has a soft pulse, he gives him nitroglycerin. He needs protection from pus organisms. Have we any remedy for this? Yes. Oxygen. Turn the patient out-of-doors. There is one remedy that will aid, that is creosote, if the stomach bears it. Other remedies may be employed for special needs, but none of them are of more importance.

Dr. J. N. Upshur, Richmond, Va., believes the cardinal principle in the treatment of tuberculosis is to preserve the integrity of the stomach, so as to antagonize action of these agents which cause loss of nutrition; further, that the great means to promote this action of the stomach are abundance of sunlight and fresh air and allowing only such foods as are easily digested. And in this line, the fewer drugs you put into the stomachs of patients, the better for them. He considers no drugs of use except in the line of improving nutrition of the body. He has faith in strychnin, because it strengthens the heart's action, increases the general integrity of the muscular system, and because it puts the patient in a position where he can take best advantage of the fresh air and sunlight. One of the most important questions is that of environment. He referred, in illustration, to the present condition of the southern negro, in contrast to his ante-bellum condition. Then his black greasy skin and well-nourished body, showed that he worked in the country where he got the most fresh air. He had an abundance of corn bread, of fat bacon and fresh vegetables. He lived in well-ventilated apartments, and was obliged to keep early hours. The speaker remembers these happy creatures, whose songs were heard all over the land. Their health was an object of intelligent care, at that time, and they were rarely sick, and, when ill, they were cared for. But now the picture has changed. The environment of the negro is different. He moves to the town. He lives upon partly-tainted meat and stale vegetables, and eliminates from his diet corn bread and bacon. He is overcrowded in his sleeping-rooms, his habits are irregular, and he often uses alcohol to excess. Now, what is the result of this contrast? Before the war, pulmonary tuberculosis in the pure negro was unknown. At the present time it is so general that the race is becoming decimated. It is increasingly frequent and of itself will solve the social race problem. The speaker differs with Dr. Solis-Cohen in the recommendation to use nitroglycerin. It causes prostration and nausea, and a soft pulse, with dilatation of the retinal vessels; but the cardinal principle is that the weak suffer from it more than the strong. Moreover, it reduces the oxygen-carrying power of the blood and interferes with the function of the red blood-corpuscles. The nitroglycerin produces its effects by paralyzing the blood-vessels and reducing blood-tension. What is desired, on the contrary, is to obtain increased circulatory power to improve general nutrition. Strychnin is the preferable agent. Nitroglycerin is positively contraindicated in a condition like pulmonary tuberculosis in his opinion.

Dr. S. Solis-Cohen said that he had been misunderstood with regard to the use of nitroglycerin and that he does not consider it applicable in the late stages when the pulse is rapid and of low tension. On the other hand, in the prebacillary stage, when improved circulation, local and general, is necessary for nutrition, it is extremely useful. He does not rely on drugs and holds the view that there is no true specific for consumption, but in certain conditions, as stated certain drugs are useful.

Dr. A. Mansfield Holmes—It is a recognized fact that the best results are obtained in the treatment of pulmonary tuberculosis when we attack the disease in the early stages: whether we discover the bacillus or not, it is very vital to the patient that we recognize the disease early. It was not the purpose of my paper to claim that it is possible to detect the very moment when the bacilli find a lodgment in the tissues. I wish to lay special stress on the point of localizing the disease at this early period as offering the greatest opportunity for therapeutic measures and the favorable moment for successful treatment.

THREE CASES ILLUSTRATING CEREBRAL COMPLICATIONS OF OTITIS MEDIA SUPPURATIVA.*

CHARLES W. RICHARDSON, M.D.
WASHINGTON, D. C.

It is not to be wondered at that, however brilliant the diagnosis may be, and however skilfully the operation may be done, success does not always attend work along the line of otitic cerebral surgery. The localization of the lesion is not always clear. Lesions may exist other than those made clear through the grouping of symptoms, and the pathological changes exposed may have progressed so far as to preclude the possibility of successful issue, all of which are independent, in the light of our present knowledge and skill in diagnosis and surgical intervention. It therefore becomes incumbent upon us to report not only our successes, but more imperative to report our failures, as through them not only we, but likewise others may profit. I fear that we are too prone to report our successful cases and too apt to forget our failures. To be sure it is no disgrace for one to fail in relieving a helpless or moribund patient, but nevertheless the human mind is so constructed as not to wish to subject failures to the close scrutiny of criticism. I shall report to you two fatal cases of sinus thrombosis and one of cerebral abscess.

Case of Sinus Thrombosis, No. 1.—On Sunday evening, Nov. 18, 1898, I was requested to see in consultation a patient who had been sick for six or seven weeks with chills and fever, and was told that the reason for my being called was on account of an otitis media purulenta, which had been latterly thought to have some relationship with the general condition. The patient was a man of 60 years of age, probably the average height, and well nourished. The physician in attendance gave me the following history. The patient had had a suppurative otitis of the right ear for many years, and during the past year, under the care of Dr. W. K. Butler, a polypus had been removed from this ear. The patient had been sick about two weeks previously with symptoms that simulated those of malarial fever. He had had chills followed by fever, the temperature rarely going above 101. The sweating stage was usually very pronounced. There had been almost constant headpain, located over the parietal. Several days before calling me in attendance he developed vertigo, and the Doctor noticed that there was tenderness over the mastoid region. On examination of the patient, I found him apparently mentally normal. He recalled incidents and answered questions intelligently, and in various ways showed perfect cerebration. There was pain noted on deep and firm pressure over the antrum mastoideum, and tenderness of an exquisite character on slight pressure over the point of exit of the emissary vein. The jugular region appeared quite normal, although there was some tenderness on pressure along the vein high up in the neck. The patient complained of intense vertigo and persistent headache. The facial expression was bad, and the skin sallow. The tongue was dry and foul and the bowels constipated. The pulse was good in volume, but slightly irregular. The pupils reacted normally, and there was no evidence of facial or other paresis.

Examination of the ear elicited no noticeable swelling or redness about the mastoid. The auditory canal was filled by an offensive pus, which was cleared away by syringing. Inspection showed that there was complete destruction of membrane, with exfoliation of ossicles. A small granulation was noticed at the posterior superior margin of the meatus. I confirmed the Doctor in his fears of intracranial complication, and gave as my opinion that we had before us a case of sinus thrombosis of the right sigmoid sinus and advised operative intervention. An ice bag was applied to the mastoid and calomel given. The next day the patient was seen again, and we found he had had a bad night, slightly delirious, and had a severe chill, with a temperature of 104. The mental condition was not quite as clear as on the previous evening. There were doubtful evidences of aphasia. Pulse was intermittent. The patient was immediately removed to the Columbian University Hospital and operated on at once.

At the time of commencing the operation the patient's condition was bad. A free incision was made through the soft tissues, as in the usual mastoid operation, and the mastoid well exposed. From the superior end of the incision, a second incision was carried backward almost to the occipital protuberance. The flaps were dissected up, exposing a roomy field. The mastoid was opened through an ivory-like process. Just before reaching the antrum, a nasty, offensive, syrupy, currant-colored fluid was exposed. The mastoid was cleaned up into the antrum and the exposure of the sinus was immediately resorted to. With the aid of rongeur forceps, the sinus was exposed throughout its whole length. The walls were found to be gangrenous, varying in color from a pasty white to green and black in spots. The wall was opened and the vessel found to be filled with a nasty, broken-down clot. The curette was used, and by following up the blood-clot posteriorly within the sinus wall the circulation was restored in this direction. The blood was stilled by a packing of iodoform gauze. Dr. Van Rensalaer then exposed the jugular in the neck. The vessel was found to be collapsed, and the clot therein had undergone organization, so that it was almost impossible to separate the walls of the vessel from each other or from the clot. The vessel was removed. No circulation was established from below. The wounds were closed and dressed and the patient placed in bed. The patient showed only slight shock after the operation and his general condition was about the same as previous to the operation. After recovering from the ether he was as rational as in the pre-operative period for several hours, when he lapsed into a semicomatose state with muttering delirium. The patient died twenty-six hours after the operation, as a result of the intense sepsis. During the period following operation and before death he had two distinct chills, with a temperature ranging from 102 to 106. Autopsy was not permitted.

Case of Infective Thrombosis, No. 2.—On Nov. 25, 1899, there was admitted into my service at the Episcopal Hospital, John J. Murphy, white, aged 25, a farmer by occupation. This man had had during the previous summer an otitis media suppurativa, which ran its usual course until the middle of October, when there was developed considerable pain back of the ear over the mastoid region. This pain continued for about two weeks, when there was added to it another symptom, a swelling over the mastoid, which gradually increased until the patient presented himself at the hospital. As will be seen by the history of the patient, he evidently had a mastoid abscess of about six weeks' duration when he entered the hospital. The mastoid swelling was intense and extended up to near the vertex of the skull and well down to the tip of the mastoid, showing a great, boggy, fluctuating mass. His general condition was bad, his temperature 100.8, pulse 70, respiration 18. His skin was sallow and he presented a decidedly emaciated appearance. I saw him first on November 25 at 8 p.m. He was operated on the next day at 4 p.m. This was the ordinary mastoid operation, and the whole cellular structure of the mastoid was found to be completely destroyed. At the time of the operation there was a slight inflammatory swelling in the neck just below the tip of the mastoid. As is often the case, where there is no fluctuation, this cervical cellulitis subsides after the opening of the mastoid cells and the evacuation of the pus, so it was therefore decided not to interfere with this condition. The patient continued in good condition until November 30, when the first dressing was made. The temperature that morning was 102.6, the first decided elevation of temperature since the primary operation. When the dressings were removed it was noticed that the induration in the neck had broken down and formed a large abscess cavity. A free incision was made, extending down over the neck to a point on a line with the upper border of the larynx. This was followed by the evacuation of a great amount of pus and broken-down tissue. The pus cavity extended up under the lower jaw and back under the trapezius muscle. The patient's condition continued along fairly favorable, with nearly normal temperature, varying from 98 to 99.6, until December 15. At this time there was noticed a commencing induration in the anterior portion of the temporal region. The patient was then etherized and this condition was opened up, when it was found that deep down under the temporal muscle there was a collection of pus. On pressure over this boggy mass, I noticed that the pus issued, not between the temporal fascia and the periosteum, but into the depths of the wound in the mastoid itself, showing that there was a direct connection between the pus cavity in the temporal region and the mastoid cells, or in other words, that the pus was evidently entirely within the bony walls. I therefore decided to continue the incision from the anterior portion of the temporal region directly backward to my mastoid wound, and upon opening this flap and throwing it back I found that just above and in front of the zygoma there was a carious perforation of the outer table. I then inserted a probe and found that it would extend well up through the squamosa into the parietal bone between the outer and inner table. It is quite evident that I had a decided case of osteomyelitis. I, therefore, with a rongeur cleared off the whole outer table of the squamosa and the lower half of the parietal bone until I came to healthy osseous tissue. This was followed by a curetting of the outer surface of the inner table of the squamosa and parietal bone. The patient's condition then continued fairly well, with a slight septic temperature, varying between 99 and 100 for four or five days, when the temperature again dropped to the normal and so remained, the patient apparently improving in his general condition during this period. On December 25 the temperature again showed a slight elevation, running up to 102.2. At this time he complained of pain in the occipital region and showed slight indisposition to sleep. On December 26 the temperature ran up to 104.2. At this time there was noticed a collection of pus well back in the occipital region. The abscess cavity was opened, and an incision was carried forward, connecting with the original mastoid wound. It will be seen by these frequent small abscess formations and the osteomyelitis which developed in the squamosa and the parietal bone, that the patient was in an intensely septic condition. The patient's condition then continued fairly well, the temperature dropping back to the normal, and with improvement in his general condition again, until January 2, when another alarm was sounded by the temperature jumping up to 102.4. I watched carefully for any evidences of further infection on the surface of the head and neck, and could see no reason for suspecting pus about the wound in the neck or elsewhere in contiguity to the wound. There was practically no pus issuing from the wound and it was granulating up in excellent style. At 11:30 on January 3 the temperature ran p to 104, and at 1:30 of the next morning, January 4, it reached 105.2. This was followed by profuse perspiration. The same day at 3:30 he complained of chilly sensations and nausea, the chill lasting twenty-five minutes. The temperature ran up to 104.8. On the next day, although his temperature remained normal practically throughout the morning, I decided that the patient had evidently a septic sinus thrombosis involving the sigmoid sinus and that immediate operative interference was demanded. The operation was done in the afternoon of Jan. 5, 1900. The old wound was opened up and an opening made into the osseous structure, which was found to be very dense over the sigmoid sinus. The sinus was exposed at the knee and carried backward an inch or more and opened up well down toward the bulb. The walls of the sinus were tense and slightly discolored, and upon opening it was found to be filled with broken-down clot. I curetted out down to the bulb and obtained a return circulation from below. On curetting backward, toward the torcular, at first a well-organized clot was brought out, then a softened clot, and going back as far as I could, nearly to the torcular, I could not get a return circulation in this direction. It was deemed best not to interfere further, and after thoroughly cleansing out the wound, the patient was put to bed. On the next day the temperature did not rise above 100. The wound was irrigated daily. The second day after the operation the temperature was 99.8 in the morning and 99.6 in the evening. The third day the patient was eating, sleeping, and feeling better than at any period during the whole stage of his illness. On January 9 the temperature was 100 in the morning, 100.2 in the afternoon, and 99.8 at night. The bowels, which for the week previous had been very loose and attended with a good deal of mucus and bloody discharge, had now returned to the normal condition and had been so since the first day after the operation. On January 10 the temperature did not rise above the normal. This evening, for the first time since the operation, the patient complained of pain in the head again. This pain was more general than at any previous stage of his illness. On January 11 the patient's morning temperature was normal, the evening temperature 100.2. The patient felt, slept and ate well, and had large, well-formed movements. On January 12 the temperature was 100 throughout the day until evening, when it went up to 100.8. The patient appeared very restless and could not sleep; seemed to be growing anxious about his condition and extremely irritable. On January 13 he suffered a great deal of pain in the head; felt chilly; temperature throughout the day was 102.2. Irritability was very marked. The patient vomited a quantity of green fluid. January 14, temperature was 103.8. He suffered intense pain in head; was extremely restless, irritable, and could hardly be kept quiet in his bed; complained of feeling badly and uncomfortable. Urine was passed involuntarily. There was no evidence of muscular paralysis or loss of sensation. Stimulants and food were refused. It was evident that the patient was developing or had developed a meningitis, and there seemed to be no apparent hope from further operative intervention. The case went from bad to worse until January 18, when he died. Vain efforts were made to obtain an autopsy, but the family absolutely refused it.

---

* Presented in a Symposium before the Section on Laryngology and Otology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

CEREBRAL ABSCESS, CASE No. 3.—On September 15, I was consulted by a gentleman 63 years of age, who had, during a visit to Atlantic City, while in bathing, developed an abscess of the right ear. This continued under treatment until September 15, when he called upon me. At that time, on examination of the ear, I found a small perforation of the membrana tympani at the posterior superior quadrant. His general condition was good and there was no tenderness or other evidences of involvement of the deeper structures of the auditory apparatus. I watched the case for several days, treating it in the usual manner, and then, as the drainage did not seem good, I enlarged the opening in the membrana tympani. During this time, and until about October 10, the case progressed favorably, with a greatly diminishing amount of purulent discharge, until about October 15, when there was absolute cessation of purulent discharge with closure of the opening in the membrana tympani. There was considerable impairment of the hearing and the patient was kept under observation and treatment in order, if possible, to bring the hearing up to normal. About the first week in November I noticed that the patient was a little more excitable than at any previous period of the treatment of his case. On about November 12 I became so impressed with his nervous state and his tendency to become excited and the alteration of his general manner that I consulted his family in regard to these facts to elucidate if they had noticed any alterations in his general demeanor. They rather assured me that he was about the same as he always had been. This continued for a period of about four or five days, when the family began to notice those things to which I had called their attention. He became morose, with a tendency to have crying spells, getting excited on slight provocation and unusually irritable to his wife and children. For about five days before this, that is, about November 7, the patient called my attention to an intense frontal headache, which had persisted now for about a week or ten days without interruption, and seemingly situated over the supraorbital notch. At this time I thought it best to confine him to the house and to bed, and on November 18 I first noticed that the patient showed some evidences of amnesic aphasia. I then told the family that I feared the patient was developing an intracranial complication, and at my suggestion, Dr. A. B. Richardson, superintendent of the Government Insane Asylum, was called into consultation. With Dr. Richardson, I went carefully over the case, and he was rather disinclined to accept my views with regard to the possible existence of a cerebral abscess. The temperature had been normal throughout. There was no alteration in the circulation nor in the respiration. There was no motor paralysis nor alteration of sensation and the reflexors were all normal. Examination of eyeground was made by Dr. Shute, but on account of the existence of a cataract, it was impossible to learn anything from this investigation. On the 23d this aphasic condition had increased a great deal, his irritability had become more marked, and there was elevation of temperature for the first time, the temperature registering 99.5. The pulse showed a slowing, dropping five beats from the normal with this patient. Dr. Richardson was again called in consultation on the 25th. We then went carefully over the case again, and we noticed that besides the amnesic aphasia there was also commencing evidence of word-blindness. There was still no alteration in sensation or motion, the patient locomoting with perfect ease. Dr. Richardson then became of the same opinion with me, and located the abscess in Broca's triangle. The patient was taken to Providence Hospital, and on the following day at 2 o'clock he was operated on. The headache had subsided about four or five days before the operation. I first did the preliminary mastoid operation, opening up into the mastoid cells without finding any evidence of a diseased condition therein. I then exposed the skull in the usual manner and took out a button of bone about an inch and a quarter above the external auditory canal. On exposing the dura there was distinct bulging and absence of pulsation. I then felt tolerably certain that there was pus within the cranial cavity. I first went in with a large-sized aspirating needle in the region forward and inward, where we had expected to find the pus. I then went inward and then downward and inward, and then backward. This was followed by the use of a grooved director in the direction that had been previously used, without the detection of any pus. Dr. W. P. Carr, who assisted me, was then given free rein in the cerebral cavity. He also failed to locate pus. At Dr. Foster's suggestion, the wound was enlarged backward, so that a better opening could be obtained, so as to get into the occipital lobe of the brain. Probing back in this direction also failed to evacuate pus. We all felt that sufficient exploration had been made, although we were confident that there was pus within the cerebral contents. The patient's condition remained about the same for twenty-four hours; on the second day he relapsed into a semi-comatose condition, and died on the third day. On post-mortem, a small abscess about the size of a hickory-nut was discovered on the mesial side of the uncinate convolution of the temporo-sphenoidal lobe. It is almost impossible to conceive how this abscess was missed during the probing. Of course, many reasons can be surmised as probable causes. On examination of the brain, which I have brought with me, it can be seen that the opening was made in a direct line with the abscess, and only about an inch and a half from the outer wall of the capsule of the abscess. In all probability, during one of my manipulations, the instrument in use must have entered the abscess cavity, the pus being either too thick to flow, or the softening of the contents of the abscess not being sufficiently advanced to admit of its readily passing out through the opening made.

With regard to operative intervention in septic thrombosis of the sigmoid sinus, early diagnosis and prompt intervention is the keynote to a successful result. The operation in itself is not a dangerous one, and should not be attended with much more shock and disturbance of the general system than the ordinary mastoid operation. Unfortunately, in this condition in the formative stage of infection, we have no symptoms or groups of symptoms which would lead us to suspect that a septic phlebitis is about to take place. Usually the first positive symptom manifested is that showing that the general system is infected, as is evidenced by the pyemic rigor and fever curve. Occasionally we may have slight fever curve preceding the pyemic chill for several days, but this does not point to any particular condition, only serving to put us in the expectant state. Here it is well to bear in mind the observation of Ernest Leutert in this connection, and that is that continuous fever lasting for several days after the subsidence of the acute symptoms in acute otitis suppurativa, wherein there is free exit to the purulent discharge, but more *particularly in* the chronic otitis suppurativa, without acute exacerbation of symptoms or retention of pus in the middle-ear cavity, is almost an exceptional symptom of a forming sinus thrombus. In the early stages of thrombosis the local symptoms do not indicate more than a possible mastoiditis, even if they indicate that, and if thrombosis is detected, it is only done during the mastoid operation. Gerhardt's symptom is one that may be of aid to us during this stage of the affection. What is particularly desired in connection with the symptomatology of *infective sinus thrombosis is careful scrutinization of all* mastoid cases with regard to their symptoms, in order that in those in which there follows thrombosis, or in which it is present at the time of operation, although undetected, we may by so doing pick out a group of symptoms which would render probable a diagnosis of infective thrombosis at this early stage of its formation. During the second stage, characterized by the formation of the thrombus and its commencing disintegration, the symptoms are usually so characteristic in most cases as not to escape the detection of the skilled aurist. While *it is true that the aurist would invariably diagnosticate* a thrombus at the first rigor and chart reading, it invariably is not so in the case of the general practitioner. We must recognize the fact that the general practitioner is, *and has a right thereto, treating very many cases of* chronic and acute suppurative otitis, but unfortunately he does not recognize the possibility of these cases as the aurist does, nor is he prepared to recognize the import of distinctive symptoms of grave intracranial lesions. We can not too often call to the attention of the general practitioner the fact that the occurrence of a chill, a *high temperature and a sweat in a patient suffering with* a suppurative ear is not an evidence of malaria, but is a symptom of extreme gravity, indicating an involvement of the sigmoid sinus, and which should be given immediate operative attention. In the present day no one practicing otology hesitates at operating at once upon an exposed diseased sinus, or in exposing and opening the sinus when the symptoms indicate that an infective thrombus is forming therein. The technique is recognized as comparatively simple, and all are universally a unit, excepting with regard to the treatment of the internal jugular. One can not but accede to the fact that the line of safety lies in the ligation of the jugular. Even though a return circulation be obtained, this does not prove conclusively that the walls of the jugular are not already involved in the phlebitic inflammation, and that thus below our seat of operation and apparent safety we may still have a source of general systemic infection. That *cases recover without jugular* ligation does not prove that many more might have been saved had jugular ligation been resorted to in all cases. The ligation and excision of the jugular does not add much to the gravity of the case, and may add greatly to its future welfare. Whether *the ligation should be* resorted to previous or subsequent to the exposure of the sigmoid sinus depends largely upon the condition manifested at the time of operation.

With regard to cerebral abscess, *the diagnosis is not always an easy question,* although at times, owing to its *distinctive localization and non-involvement of other* structures, the signs are clearly marked. Subdural abscess gives rise usually to no distinctive signs until the *meninges are involved.* The early and most characteristic symptoms of *cerebral abscess are those of alteration* of the general demeanor of the patient, the patient becoming anxious, irritable, morose, and semi-hysterical. *I should look upon this symptom as an exceedingly suspicious sign in a person affected with a suppurative ear.* Another symptom which I think can not be too often called to our minds is the evidence of aphasia, especially *in cases of left-sided otitis in right-handed persons.* As the usual seat of lesions in otitic cerebral abscess is in the temporosphenoidal lobe of the brain, and as we *know that the localization of the speech center is not limited to one small area of the brain,* we can readily understand how an abscess anywhere in the temporosphenoidal region is apt to involve some of these centers or some of the associate fibers, giving rise as its *earliest manifestation, to some alteration in the function* of speech. Unfortunately the speech center is not a simple affair, localized in a single center, but rather a *complex thing, resulting from the action of many brain* centers. It extends from the Rolandic region backward into the temporal region and upward as far as the angular gyrus in the occipital lobe. While we see that the presence of aphasic symptoms in a person suffering with suppurative otitis is quite a positive sign of cerebral abscess, yet it does not give us the positive seat of the lesion or its localization. The most probable seat of such an abscess is in the white matter of the under surface of the brain in the region of the uncinate or third convolution. The seat of such an abscess would be *in a direct line inward, varying from an inch to an* inch and a half in depth from an opening made in the skull cap one inch above the external auditory meatus.

SUPPURATIVE TYMPANO-MASTOIDITIS IN CHILDREN.*

HERMAN KNAPP, M.D.
NEW YORK CITY.

When you did me the honor to invite me to address this Section I thought tympano-mastoiditis in children might be an appropriate subject to open a discussion on that part of otology, which, at present, receives the greatest attention—the surgery of the tympano-mastoid.

Like others, I have found the affections of the tympano-mastoid particularly difficult to manage in children. *Not only the difficulty of the subject, gentlemen,* but also its paramount importance, determined me to submit some remarks for your consideration. As to the importance I need only repeat what has often been said, viz., that he who has no hereditary tendency to deafness and guards his hearing organ safe through all the diseases of childhood, is almost immune from ear trouble *in after life. What causes the management of* ear disease in childhood to be so difficult and irksome? This question leads one to the etiology of ear disease. In order to learn at what age cases of serious ear disease are most numerous I have tabulated the mastoid operations performed on children under 8 years at the New York Ophthalmic and Aural Institute, during the last six years. They are 39 in number. Of these 7 (18 per cent.) occurred in the first year, i. e., from birth to the completion of the first year; 9 (23 per cent.) the second year; 3 (7.6 per cent.) in each of the third, fourth, and fifth years; 4 (10.2 per cent.) in the sixth year; 5 (12.8 per cent.) in the seventh year; and 5 (12.8 per cent.) in the eighth year. Of the children who had mastoid abscess in the first year, 2 were two months old; 1 four months; 2 seven months; 1 ten months, and 1 eleven months. This classification shows that the greatest percentage was in the second year; then came the first which gives the first two years of life 41 per cent., against 59 per cent. in the six subsequent years. As to the deductions suggested by these numbers, I dare say that they are not conclusive, because the material of a public clinic deals chiefly with patients that are more or less transportable. Children in the first year of their lives are not so movable as those that can walk. Yet, small as the above numbers are, they demonstrate a preponderance of this disease in the earliest childhood over following years.

---

* Presented in a Symposium before the Section on Laryngology and Otology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

The grave ear diseases, I mean those that show mastoid affections and their complications, are not only more frequent, but also more dangerous, and more difficult to treat in childhood than in adult life. What is the cause? I think we are all agreed that the cause lies in the anatomical conditions in the infantile ear and its adjacent parts, the nasopharynx. Lodged in the nasopharynx, the great originator of ear disease, is the belt of adenoid tissue in the upper part of the pharyngeal cavity which, among other parts, encroaches on the Eustachian tubes and even dips somewhat into their mouths. It would be carrying owls to Athens were I to say more about it before this Section. The peculiar conditions of the auditory organ are responsible for the easy transportation and pernicious development of infective material from the nasopharynx into the ear. The anatomy of the ear is difficult to master. It is not only most intricate in its finished state at the age of maturity, and later, but it is so undeveloped at birth, and grows so slowly that the ear surgeon should make a special study of the condition of the ear nearly every year in the first decade of his patient's life.

The shortness and comparatively large caliber of the Eustachian tube present favorable conditions for the ready admission of material from the nasopharynx into the tympanic cavity. This accounts for the frequency of tympanic disease in children, but also for the favorable condition of spontaneous liberation of serum, phlegm and pus from the middle ear back into the nasopharyngeal cavity and thence into the respiratory and digestive tracts. The easy inflation of children's tympanic cavities, even without the act of swallowing, is well known.

The particular importance of an early diagnosis and treatment of suppurative otitis media in children resulted from the anatomical conditions, viz., a resistant drumhead, easy transfer of infective material from the nasopharyngeal cavity into the tympanum, attic, and both outside and inside the skull. As there are not yet any mastoid cells, but pneumatic cancellous tissue in the base of the squama, we see the abscess rather above than back of the ear. In some cases, these abscesses, characteristic and well developed, disappear over night and the patient gets well quickly and permanently. Where have they gone? They have passed through the large infantile Eustachian tube into the throat. When we evacuate them, by operation, we must not plunge a knife boldly into them, down to the bone, as we may do in adults, but make the incision carefully, layer by layer, bearing in mind that the bones of young children are soft and connected with one another by membranous sutures, more or less broad, all of which can be clearly seen on the skull of a 6-months' old child. The easy path which, in another case, leads the pus into the middle cranial fossa, with its fatal consequences, is just as plainly demonstrable. The masto-squamous and petrosquamous sutures as ready channels of morbid material are now generally known and appreciated. The petrosquamous sinus of children which in some cases does not obliterate very early, exceptionally remains persistent, is seen on the inside of the skull, passing through a foramen which outside is situated behind the glenoid fossa and the tympanic ring. This sinus, well described and depicted in William Macewen's inexhaustible book —in Figs. 1 and 2, opposite page 2—has of late drawn the attention of the otological world through a case, published by Dr. Cleveland, of Philadelphia.[1] Mr. Arthur Cheattle, of London, has made "une étude approfondie" on this subject, exhibiting 6 or 7 skulls where the foramina were well seen, at the unique museum of the Sixth International Otological Congress, at London, last summer. He gave a good description of that sinus, acknowledging, as the speaker does, his gratitude to Dr. Cleveland for having given him his first knowledge on this not well-known subject.

SOME OBSERVATIONS IN MASTOID OPERATIONS.*

A. W. CALHOUN, M.D., LL.D.

ATLANTA, GA.

So much has been written upon this subject that it would seem that little remained to be said; yet the gravity of mastoid disease is such as to promptly arouse our attention and apprehension, and lead us in each instance to vigorous treatment, and therefore every observation should be of interest.

The disease, in certain seasons of the year, often prevails in almost epidemic form, and again occurs at such wide intervals as to attract notice by its infrequency, but I dare say no case ever presents itself to any one of us without causing us the deepest concern for the welfare of our patient. The anxious, distressful countenance of a typical mastoid subject at once elicits our earnest consideration and demands our most thoughtful care and treatment. The possible unfavorable result in each case brings before us vividly the fact that we have a grave disease to deal with, and that we must act promptly and decisively.

During the last year I have treated twelve or fourteen cases of mastoid disease, varying in age from 8 to 50 years, and the operations I propose to speak of were made while attending these and previous cases, running back through a series of years. I do not intend to recite details of each individual case with accompanying symptoms, but will say they were just such as we all see—some very severe, some less so—but all requiring operative measures more or less radical; most of them necessitating the removal of the outer wall of the mastoid bone and the thorough curetting of the cavity, and all fourteen making good and complete recoveries.

Reviewing these cases, and studying them and the disease as it occurs in my section of the country—Middle Atlantic States—has led me to the following conclusions:

In the first place, I would call attention to the infrequency of mastoid disease as compared with the total number of cases of acute and chronic middle-ear suppurations. It has occurred to me that we have more than our proportion of middle-ear suppurations, running their course and getting well, or going over into the chronic state and becoming often a fixture with the individual. But even with a large number of these latter cases the comparative rarity of mastoidal complications has been conspicuous and a matter of observation. On the contrary, in other sections of our country I learn from medical friends that the disease is very frequent, occurring much oftener in an equal number of chronic and acute middle-ear suppurative inflammations. This has been particularly the case during the past winter in many of the large eastern cities, where, as a sequel to la grippe, mastoidal complications have prevailed to an alarming degree. Doubtless, the mildness of the climate will furnish the explanation of the small number of cases, as compared with their frequency in other sections having a harsher climate. The observation to which I would like to call your attention is that while mastoiditis is more frequent in some sections than others, it is yet an uncommon complication everywhere when the vast number of the acute and chronic suppurations of the middle ear are taken into consideration. One would naturally expect to find a large percentage of such cases, after viewing the intimate relationship of the tympanic and mastoidal cavities, remembering the violence of the inflammation in the former cavity.

---

* Presented in a Symposium before the Section on Laryngology and Otology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

[1] Archives of Otology, xxiv, p. 236, 1895.

The mild type of the mastoid inflammation in the cases treated during the recent winter also deserves attention. In each the usual symptoms were present, viz., fever in most cases, but absent in some; the characteristic swelling, not always great; pain, and the ever-present distressed countenance, etc. Owing, doubtless, to climatic influence, there has been marked freedom from cerebral and other dangerous complications. This has not been the history of the disease, as recently occurring in more northerly sections. In a great majority of the cases the damage to the hearing has been slight, the patient regaining much if not all the hearing lost as the result of the mastoid complication. This is a matter of surprise when one recalls to mind the changes and disturbances which take place from the inflammation and the operative procedures within the mastoid cavity.

Age has played no rôle in the series of cases more recently in my hands, the disease occurring about equally often in children and adults. I know no reason why the negro should be exempt from this affection, but I recall but one case of mastoid inflammation in the negro. I have had abundant opportunity to study the many diseases of the black race, and after a large experience can state that the negro is much less susceptible to middle-ear diseases than the white race; and being thus less susceptible it follows that mastoidal complications should be very rare with him.

I have observed sometimes very serious mastoid disease without any such marked symptoms as swelling, pain, etc., and but little abnormal temperature. Recurrent slight acute attacks would finally lead to the decision that operative measures were needful, and the operation would develop the fact that very serious inflammation existed in the cavity. In a case recently operated, I found the inflammation and the destructive processes in the cavity out of all proportion to the external and constitutional symptoms. Cases also now and then present themselves where the mastoid inflammation exists apparently without middle-ear involvement. There must have been an acute otitis media, with an extension of the inflammation into the mastoid cells, but no suppuration of the middle ear had taken place. Such a case was operated upon, in which the patient had never complained of pain, impaired hearing, suppuration or other middle-ear symptoms, yet evidences of mastoid inflammation were so pronounced that a radical operation was deemed necessary. It is an error to suppose that every case of mastoiditis is preceded by suppurative otitis media, as experience teaches us the contrary.

Again, there can be no doubt of the tendency to spontaneous and complete recovery in many cases of the disease of even severe types, for in some of these reported an operation was refused and yet a perfect cure was attained. A good result is not infrequently reached only by resorting to the Wilde incision. Such recoveries occur often enough to cause one to pause and consider whether the severe and radical operation for mastoid disease is not frequently made when a little delay might have led us to much simpler and just as satisfactory treatment. I would not like to be considered as advocating anything but prompt and thorough surgical treatment in well-marked typical acute or subacute mastoiditis, but there are cases where intelligent delay and milder measures yield just as good results as are invariably produced in the more violent cases by the most radical surgical treatment. The fact I wish to lay stress upon here is that not in every seemingly severe case of mastoid disease is it necessary to rush to radical operative treatment, but that not an inconsiderable number make good recoveries under milder measures. One of the chief advantages of the surgical treatment is the rapid and complete cessation of the middle-ear inflammation, discharges, etc., in a large majority of cases.

My experience has led me to the conclusion that such radical measures as the Stacke operation are seldom required, the disease yielding readily and satisfactorily to the less severe operative procedures; indeed, my records do not show in a single instance that it was needful to resort to the severer operations.

To recapitulate, my conclusions, based upon a large number of mastoid operations, are:

1. Infrequency of mastoid disease as compared with the large number of cases of suppurative otitis media.
2. Mild type of the disease, freedom from cerebral and other dangerous complications.
3. Comparative exemption of the negro race.
4. Presence of serious mastoid disease without marked outward symptoms, fever, etc.
5. Presence of mastoid disease without apparent middle-ear involvement.
6. Not every case requires radical operation.

[The discussion will appear with other papers of the Symposium, to be printed in succeeding issues of The Journal. —Ed.]

Malaria and Mosquitoes.—Dr. Dionisi, of Rome, has involuntarily contributed another example of the infallibility of the transmission of malarial infection by mosquitoes. A number of which he was cultivating for purposes of research escaped from their cage and stung him. After a few days of incubation he was prostrated with a violent attack of typical estivo-autumnal fever in the middle of January.

DIFFERENTIAL DIAGNOSIS BETWEEN CHICKENPOX AND SMALLPOX.

HEMAN SPALDING, M.D.
Chief Medical Inspector, Chicago Health Department.
CHICAGO.

In conversation with an eminent dermatologist recently, he made the remark that he had never seen chickenpox in an adult. I thought it a remarkable statement in so experienced a man, inasmuch as I had seen a large number of such cases while connected with the Department of Health of Chicago. I subsequently noticed a statement published in the *Cleveland Journal of Medicine,* by Dr. William Thomas Corlett, to the effect that he had never seen a case of chickenpox in an individual after puberty. A little later The Journal of the American Medical Association editorially said that chickenpox in an adult was so rare an occurrence that "it might be a safe rule in some respects to call every case in an adult smallpox that one feels tempted to diagnose as varicella."

An adult with a supposed case of chickenpox either has or has not chickenpox. If he has it, he should not be treated for something else. Chickenpox, like other eruptive diseases, as measles or smallpox, delights to visit its wrath upon children, but if by some chance a child escapes chickenpox, as often happens, there is no known physiological law that will with certainty protect this child when grown to manhood, from contracting chickenpox if exposed to that disease.

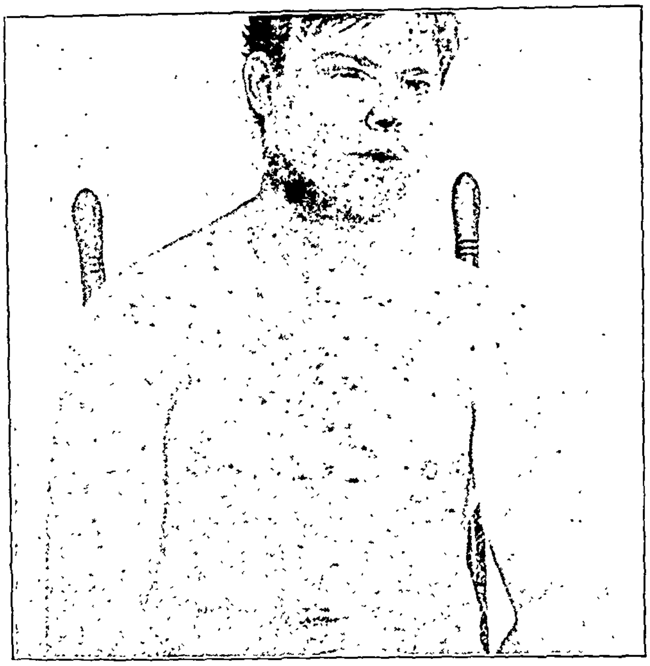

Fig. 1.—Varicella. Aged 22 years. Fifth day of the eruption. Macules, papules, vesicles, pustules and scabs from broken and dried vesicles.

I will present a case with some notes on the diagnosis. The accompanying illustrations, Figs. 1 and 2, are from photographs of a case of chickenpox in a man 22 years old. The photographs were taken on the fifth day of the disease, which was also the fifth day of the eruption. Dr. W. S. Orth, of this city, was called to see the man and pronounced the disease chickenpox. Dr. L. E. Smith saw the case with Dr. Orth, and agreed with him as to the diagnosis. I was then requested to see the patient and concurred in the opinion that it was chickenpox. Dr. John R. Neely, of the Department of Health, saw the case later and also pronounced it varicella. The following is the history:

Wm. S., 22 years old, was vaccinated with a typical result seven years previous. There were no prodromal symptoms experienced, no chill, no headache, backache, nausea nor fever. The eruption came on rapidly, but irregularly, first on the body, then the face, hands and limbs. It appeared as described, as "small blisters."

I saw him on the fourth day of the eruption and found large vesicles, large pustules, some papules and scabs from broken vesicles. This was at the height of the disease. I was unable to procure a photograph that day, but the following day Dr. Drake of the Department photographed the man. The lesions show well in the photograph, but had dried down some and are not so well marked as they were the day before. The man felt well and but for the appearance of his face would have preferred to continue about his work. Eight days after this photograph was taken he was again "tending bar."

As to the diagnosis, there was a history of exposure to a case of chickenpox in a child. In the same room with the patient was his 11-year old sister with a typical case of chickenpox represented in Fig. 3. There were no prodromal symptoms. Eruptions were vesicular and rapidly became large vesicles, quickly turning to pustules or breaking and forming dried scabs. None were deeply seated except those showing secondary infection. The vesicles and pustules were thinly covered and easily broken, and many of them were broken. The pustules on the fourth day were as mature and as large as they would be in variola on the ninth or tenth day of the eruption. There was no uniformity of development—macules, papules, vesicles, pustules, and dried scabs were abundant on the fourth day. This variety of lesions in so marked a degree could not be found in smallpox. In smallpox a man would have some prodromal symptoms with so profuse an eruption.

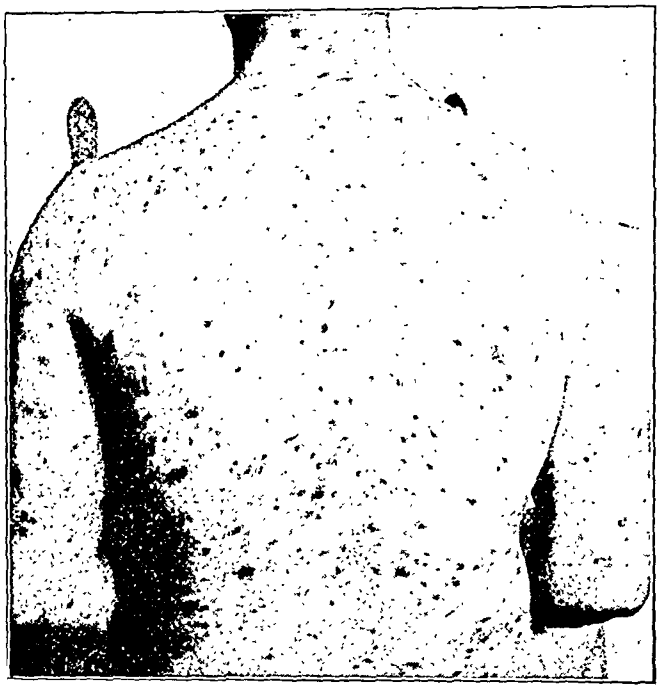

Fig. 2.—Varicella. Aged 22 years. Fifth day of the eruption. Macules, papules, vesicles, pustules and scabs from broken vesicles.

There were visitors and several unvaccinated children at this house. An unvaccinated child, sister of the patient, came home while the patient was scaling. Nothing was done to destroy contagion. The man went quency of mastoid disease as compared with the total number of cases of acute and chronic middle-ear suppurations. It has occurred to me that we have more than our proportion of middle-ear suppurations, running their course and getting well, or going over into the chronic state and becoming often a fixture with the individual. But even with a large number of these latter cases the comparative rarity of mastoidal complications has been conspicuous and a matter of observation. On the contrary, in other sections of our country I learn from medical friends that the disease is very frequent, occurring much oftener in an equal number of chronic and acute middle-ear suppurative inflammations. This has been particularly the case during the past winter in many of the large eastern cities, where, as a sequel to la grippe, mastoidal complications have prevailed to an alarming degree. Doubtless, the mildness of the climate will furnish the explanation of the small number of cases, as compared with their frequency in other sections having a harsher climate. The observation to which I would like to call your attention is that while mastoiditis is more frequent in some sections than others, it is yet an uncommon complication everywhere when the vast number of the acute and chronic suppurations of the middle ear are taken into consideration. One would naturally expect to find a large percentage of such cases, after viewing the intimate relationship of the tympanic and mastoidal cavities, remembering the violence of the inflammation in the former cavity.

The mild type of the mastoid inflammation in the cases treated during the recent winter also deserves attention. In each the usual symptoms were present, viz., fever in most cases, but absent in some; the characteristic swelling, not always great; pain, and the ever-present distressed countenance, etc. Owing, doubtless, to climatic influence, there has been marked freedom from cerebral and other dangerous complications. This has not been the history of the disease, as recently occurring in more northerly sections. In a great majority of the cases the damage to the hearing has been slight, the patient regaining much if not all the hearing lost as the result of the mastoid complication. This is a matter of surprise when one recalls to mind the changes and disturbances which take place from the inflammation and the operative procedures within the mastoid cavity.

Age has played no rôle in the series of cases more recently in my hands, the disease occurring about equally often in children and adults. I know no reason why the negro should be exempt from this affection, but I recall but one case of mastoid inflammation in the negro. I have had abundant opportunity to study the many diseases of the black race, and after a large experience can state that the negro is much less susceptible to middle-ear diseases than the white race; and being thus less susceptible it follows that mastoidal complications should be very rare with him.

I have observed sometimes very serious mastoid disease without any such marked symptoms as swelling, pain, etc., and but little abnormal temperature. Recurrent slight acute attacks would finally lead to the decision that operative measures were needful, and the operation would develop the fact that very serious inflammation existed in the cavity. In a case recently operated, I found the inflammation and the destructive processes in the cavity out of all proportion to the external and constitutional symptoms. Cases also now and then present themselves where the mastoid inflammation exists apparently without middle-ear involvement. There must have been an acute otitis media, with an extension of the inflammation into the mastoid cells, but no suppuration of the middle ear had taken place. Such a case was operated upon, in which the patient had never complained of pain, impaired hearing, suppuration or other middle-ear symptoms, yet evidences of mastoid inflammation were so pronounced that a radical operation was deemed necessary. It is an error to suppose that every case of mastoiditis is preceded by suppurative otitis media, as experience teaches us the contrary.

Again, there can be no doubt of the tendency to spontaneous and complete recovery in many cases of the disease of even severe types, for in some of these reported an operation was refused and yet a perfect cure was attained. A good result is not infrequently reached only by resorting to the Wilde incision. After a few days of incubation he was prostrated with a violent attack of typical estivo-autumnal fever in the middle of January.

DIFFERENTIAL DIAGNOSIS BETWEEN CHICKENPOX AND SMALLPOX.

HEMAN SPALDING, M.D.
Chief Medical Inspector, Chicago Health Department.
CHICAGO.

In conversation with an eminent dermatologist recently, he made the remark that he had never seen chickenpox in an adult. I thought it a remarkable statement in so experienced a man, inasmuch as I had seen a large number of such cases while connected with the Department of Health of Chicago. I subsequently noticed a statement published in the *Cleveland Journal of Medicine*, by Dr. William Thomas Corlett, to the effect that he had never seen a case of chickenpox in an individual after puberty. A little later THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION editorially said that chickenpox in an adult was so rare an occurrence that "it might be a safe rule in some respects to call every case in an adult smallpox that one feels tempted to diagnose as varicella."

An adult with a supposed case of chickenpox either has or has not chickenpox. If he has it, he should not be treated for something else. Chickenpox, like other eruptive diseases, as measles or smallpox, delights to visit its wrath upon children, but if by some chance a child escapes chickenpox, as often happens, there is no known physiological law that will with certainty protect this child when grown to manhood, from contracting chickenpox if exposed to that disease.

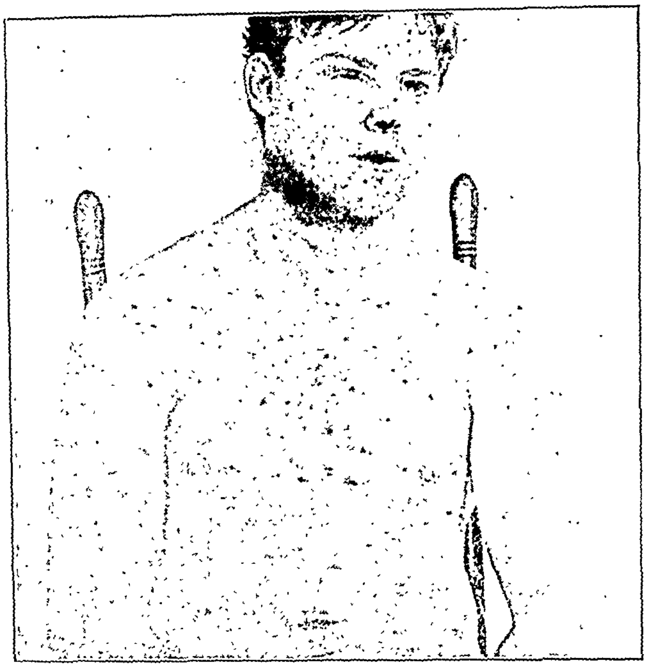

Fig. 1.—Varicella. Aged 22 years. Fifth day of the eruption. Macules, papules, vesicles, pustules and scabs from broken and dried vesicles.

I will present a case with some notes on the diagnosis. The accompanying illustrations, Figs. 1 and 2, are from photographs of a case of chickenpox in a man 22 years old. The photographs were taken on the fifth day of the disease, which was also the fifth day of the eruption. Dr. W. S. Orth, of this city, was called to see the man and pronounced the disease chickenpox. Dr. L. E. Smith saw the case with Dr. Orth, and agreed with him as to the diagnosis. I was then requested to see the patient and concurred in the opinion that it was chickenpox. Dr. John R. Neely, of the Department of Health, saw the case later and also pronounced it varicella. The following is the history:

Wm. S., 22 years old, was vaccinated with a typical result seven years previous. There were no prodromal symptoms experienced, no chill, no headache, backache, nausea nor fever. The eruption came on rapidly, but irregularly, first on the body, then the face, hands and limbs. It appeared as described, as "small blisters."

I saw him on the fourth day of the eruption and found large vesicles, large pustules, some papules and scabs from broken vesicles. This was at the height of the disease. I was unable to procure a photograph that day, but the following day Dr. Drake of the Department photographed the man. The lesions show well in the photograph, but had dried down some and are not so well marked as they were the day before. The man felt well and but for the appearance of his face would have preferred to continue about his work. Eight days after this photograph was taken he was again "tending bar."

As to the diagnosis, there was a history of exposure to a case of chickenpox in a child. In the same room with the patient was his 11-year old sister with a typical case of chickenpox represented in Fig. 3. There were no prodromal symptoms. Eruptions were vesicular and rapidly became large vesicles, quickly turning to pustules or breaking and forming dried scabs. None were deeply seated except those showing secondary infection. The vesicles and pustules were thinly covered and easily broken, and many of them were broken. The pustules on the fourth day were as mature and as large as they would be in variola on the ninth or tenth day of the eruption. There was no uniformity of development—macules, papules, vesicles, pustules, and dried scabs were abundant on the fourth day. This variety of lesions in so marked a degree could not be found in smallpox. In smallpox a man would have some prodromal symptoms with so profuse an eruption.

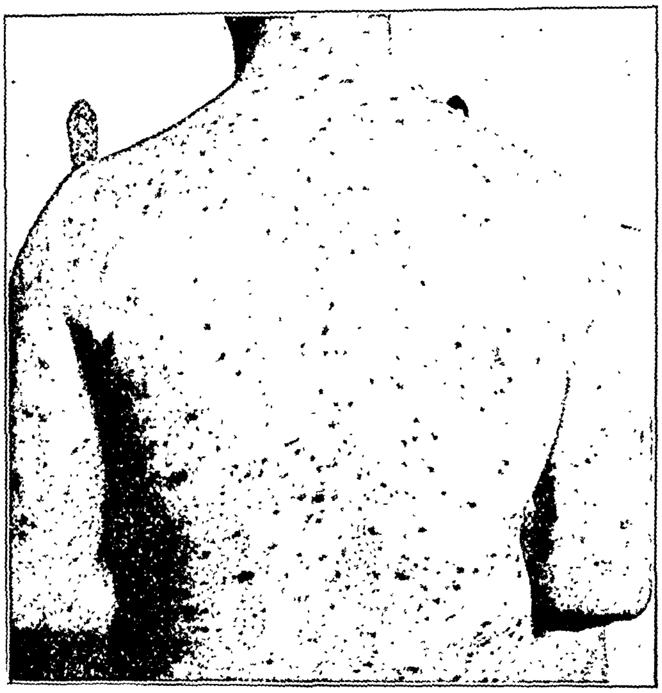

Fig. 2.—Varicella. Aged 22 years. Fifth day of the eruption. Macules, papules, vesicles, pustules and scabs from broken vesicles.

There were visitors and several unvaccinated children at this house. An unvaccinated child, sister of the patient, came home while the patient was scaling. Nothing was done to destroy contagion. The man went to his work behind the bar at a time when, if it had been smallpox, he would have conveyed the disease to others; yet no one took the disease, except one child, and she had chickenpox.

I have seen many examples of perfectly typical chickenpox in adults. The early part of 1899 Prof. Henry M. Lyman reported a case of chickenpox in a man 22 years old. I had an opportunity to see the case with Dr. Lyman. It was typical in every way, except the presence of headache for two days preceding the eruption.

It has frequently happened during mild epidemics of variola, such as is now prevalent over various parts of the country, that a mistaken diagnosis of varicella has been made, and disastrous results have followed, and I do not want to encourage any one in the belief that varicella is always easily distinguished from mild variola, but a correct diagnosis ought always to be made, for it is a serious matter to send a non-variolous patient to the smallpox hospital.

There are cases of variola and varicella with clinical symptoms of both diseases present which will puzzle the most experienced diagnostician. It must not be lost sight of that varicella does quite frequently attack adults.

In contrast to the above case, observe the character of the eruption in the case of smallpox represented in Figs. 4 and 5. This shows smallpox at the sixth day of the eruption and ninth day of the disease. There is a marked difference in the appearance of the lesions. In Figs. 4 and 5 there is no sign of the vesicles breaking down and drying into scabs, though the lesions are a day older than those in the case of chickenpox, represented in Figs. 1 and 2.

The vesicles now turning pustular are covered with the entire skin, making a protection to the vesicle so strong that it is not easily broken. These lesions are still growing in size and will continue to enlarge for four days more. The lesions in Figs. 1 and 2, five days old, are smaller than they were the day before the photographs were taken, and each day will see a diminution in the size of the lesions, except in the exceptional ones, which have received extraneous infection.

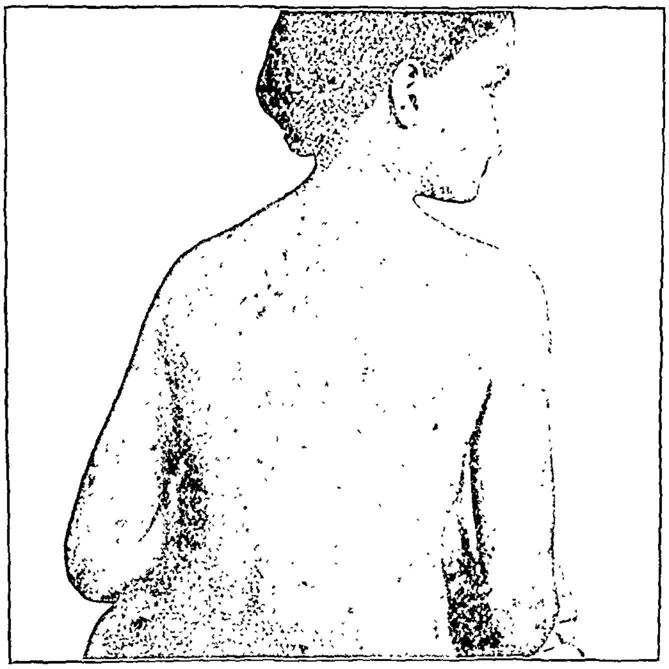

Fig. 3.—Varicella. Aged 11 years. Second day of the eruption. On right elbow three lesions caused by scratching owing to presence of urticaria.

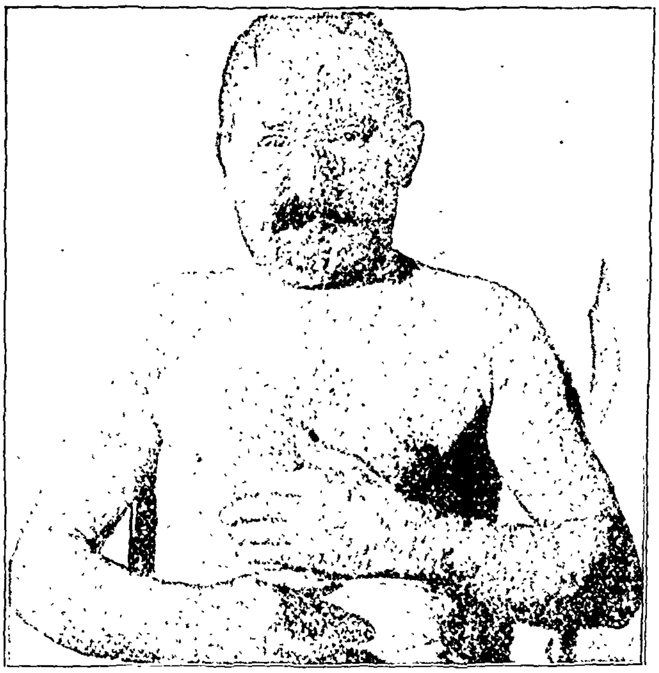

Fig. 4.—Variola. Sixth day of eruption.

The occasional occurrence of chickenpox in adults has been a source of confusion to medical men who are not in constant touch with variola and varicella and have not become perfectly familiar with the clinical aspect of the two diseases in all their forms.

A diagnosis is easily made in a typical case of either of these diseases, but in the mild form of smallpox now prevalent throughout the country, a perfectly typical case is not often seen.

These irregular forms of variola present numerous deceptive aspects. In a large proportion of the cases the eruption will appear after two days of prodromal symptoms instead of on the evening of the third or the morning of the fourth day, as is usual. In some instances there will be violent prodromal symptoms; chill, high fever, headache, backache and vomiting, followed by so insignificantly few eruptions as to be disappointing and misleading to a physician who is inexperienced in the diagnosis of smallpox.

More often the prodromal symptoms are insignificant as well as the eruption. There may be an absence of headache, or slight headache with no backache. Nausea has been very frequently present in these mild forms of the disease. These symptoms are often so mild as not to stop the subject from his work. He always feels better as soon as the eruption appears, no matter if the disease is so mild that only one or two papules appear, and if he has stopped work for a couple of days because of feeling a little sick, he will go to his work in most instances when this eruption occurs, if he is not stopped. I have found men with this form of smallpox, in the pustular stage of the disease, working in printing houses, packing houses, and factories. They felt no inconvenience and were not aware of the nature and danger of the disease with which they were afflicted.

In the mild form irregularity in development is frequently found. The vesicles fail to fill completely, will become pustular as early as the fourth or fifth day of the eruption, their contents are found to be hardened, become dry and horny and scale off before the tenth day. Some scale earlier than this. In the mild form modified by an old vaccination we frequently find a condition which is generally recognized to be a characteristic of chickenpox, but not present in smallpox, viz., as many as three stages of development of the lesions side by side. A few papules, numerous vesicles and some pustules and even scabs are found at the same time. The scabs would be the result of tearing the vesicles by scratching. These cases run their course and the lesions dry up and scale off in less than ten days.

In a few of these cases the pustules seem to involve the deeper layer of the skin so slightly that some have thought the cutis vera is not a part of the covering of the pustule. I believe the smallpox pustule always involves the cutis vera. I think this fact is the most valuable distinguishing feature about the smallpox lesion for diagnostic purposes.

The papule seems to be pushed up from below the skin, bringing in front of it as a covering, all the layers of the integument. *Hence the tenacity* of the covering of the smallpox vesicle or pustule. *It is not easily* broken and as a rule is not ruptured till the eleventh day of its growth.

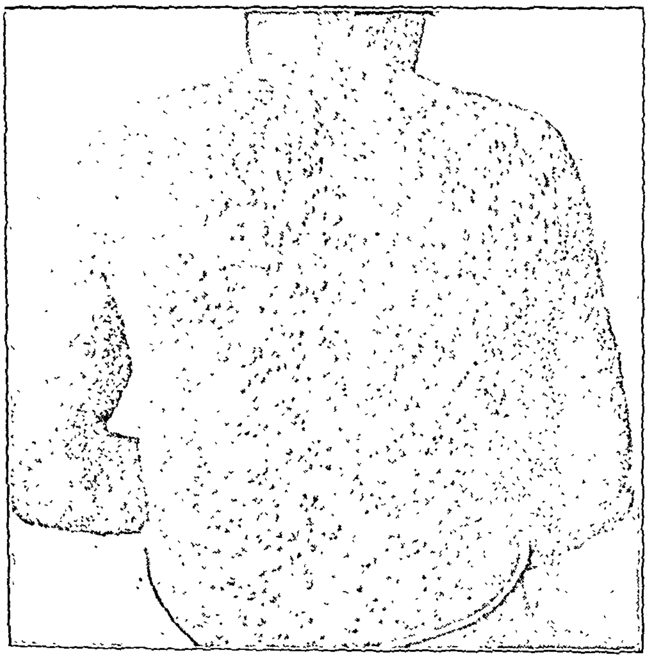

Fig. 5.—Variola. Sixth day of eruption.

Observe in Fig. 6 the deep-rooted pustules, ten days old, with thick investment, thick and strong enough to resist decay and external violence for ten days. The pustules of chickenpox, no matter how robust, will not resist decay and accidental pressure more than four or five days. Chickenpox lesions have for a covering only the outer layer of the skin. This covering is fragile, easily broken and *is* broken the first, second, third or fourth day after the appearance of the vesicle.

In the adult negro chickenpox lesions on the wrists and hands have such a thick covering that they resist destructive influences for fully five days, and if there were no typical varicella lesions over the body the diagnosis would be extremely difficult. The external layer of skin in an adult negro is thick and the eruption of varicella here looks and feels like the papule of variola, but the eruption over the body will aid in determining the nature of the disease.

It must not be forgotten that sometimes there are slight prodromal symptoms in varicella, and that in cases of mild smallpox sometimes the prodromal symptoms are very slight, so that we are compelled to make the diagnosis on the character of the eruption as presented to the eye. The diagnosis can be made, for there is a difference in the appearance to the eye, in the clinical course and development of the lesion.

In Chicago we have had an excellent opportunity to see and study mild smallpox as it has come to us during the past eighteen months from sixteen different states under the various names of "giant chickenpox," "Cuban itch," etc. Dixon, Ill., contributed six cases of smallpox to Chicago, though the disease in that city was generally known by another name. We placed all these case in the Isolation Hospital, where they ran a typical course of mild smallpox in every fact and detail. I visited three of the neighboring states where this mild type of smallpox was under discussion and found that in every instance the disease was smallpox.

While as a rule the attack is mild in this outbreak, it is not always so. We have had the confluent and the hemorrhagic form of the disease in our hospital.

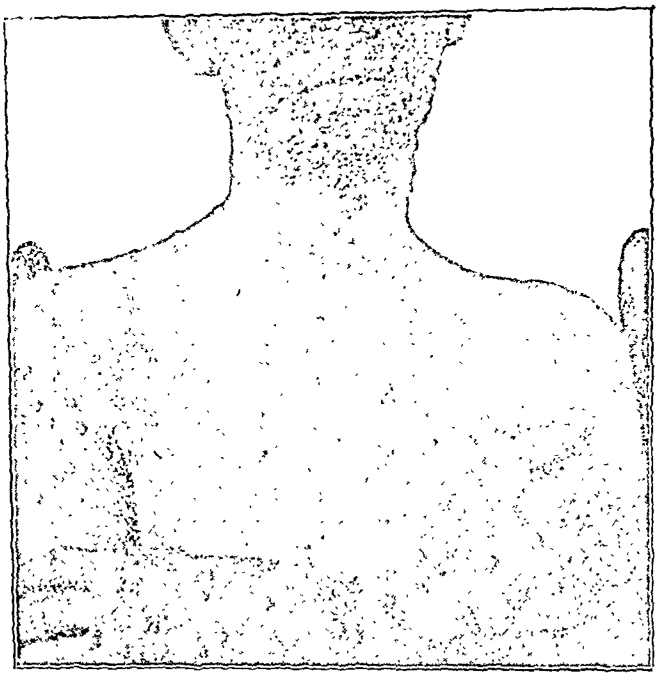

Fig. 6.—Variola. Tenth day of eruption.

A patient from Minnesota, with a mild case, diagnosed by two physicians as chickenpox, was permitted to mingle with others and visit her home in Chicago. Two of her sisters, a brother and her father, none of whom had been vaccinated, contracted the disease from her. The father and two sisters had a very mild form of the disease, but the brother had the disease in the *confluent form*, which resulted in his death in about two weeks. Here we had four people taken sick at the same time after an exposure to a supposed case of chickenpox, three of them having the disease in as mild a form as the sister who was supposed to have chickenpox, while the fourth had the disease in one of its worst forms.

In making a diagnosis of variola, remember that there will be some prodromal symptoms in the mildest cases if you are successful in getting the truth out of the patient, that when the eruption appears the patient will always feel better unless there is present some intercurrent disease, and that the fever will subside as the eruption appears. Look for the early appearance of the eruption on the vascular parts, on the face, in the throat, on the wrists and hands, on the foreskin and glans penis. If you find a papule on the ear, it will help in the diagnosis. Do not depend too much on finding umbilication of the vesicles. You will be disappointed in the mild cases, as it is often absent.

Of all the cases of smallpox sent to the Isolation Hospital in the last eighteen months, but sixteen had ever been vaccinated and these had either doubtful or very old scars.

MISSTATEMENTS ON ANTIVIVISECTION.

CORRESPONDENCE WITH AMERICAN HUMANE ASSOCIATION.

W. W. KEEN, M.D., LL.D., F.R.C.S. (Hon.)
Late President of the American Medical Association; Professor of Surgery, Jefferson Medical College.
PHILADELPHIA.

*Letter from President of American Humane Association.**

TOLEDO, OHIO, Oct. 4, 1900.

PROF. WILLIAM W. KEEN, late President of the AMERICAN MEDICAL ASSOCIATION, Jefferson Medical College, Philadelphia.

Dear Sir:—My attention has just been called to a passage in the published "Report of the Hearings" before the Senate committee, held at Washington last February, on the bill for regulation of vivisection. In this volume the following conversation between Senator Gallinger and yourself is recorded:

> SENATOR GALLINGER—What knowledge have you of the advances made by vivisectionists that have led them to progress from the brute creation to the human creation in making these so-called vivisection experiments?
>
> DR. KEEN—I presume that you refer to a pamphlet issued by the American Humane Society. I have only to say in reference to it that there were a number of experiments which I would utterly condemn. Of the experiments narrated in that pamphlet, I have looked up every one that I could. Only two are alleged to have been done in America. Many of them are so vague and indefinite that I could not look them up, but as to those that I could, some are garbled and inaccurate; not all of them, observe.
>
> SENATOR GALLINGER—Some of them?
>
> DR. KEEN—Some of them.

A statement of this character, based upon such authority, it is impossible to ignore. Proceeding from one less eminent than yourself in that profession which you represent and adorn it might pass without notice, but coming from you, sir, such a charge must be investigated and probed to the fullest extent. Its importance is evident, and in testing its accuracy you will give me, I trust every assistance within your power.

First: Regarding the cases of experimentation upon human beings recorded in our pamphlet, "Human Vivisection," you informed the Senate committee that "*Many of them are so vague and indefinite that I could not look them up.*" We challenge the accuracy of that statement, and ask for proof. Of the various series of experiments upon human beings, made for the most part upon women and children in hospitals and infirmaries, the authorities given in this pamphlet are as follows:

1. Bulletin of the Johns Hopkins Hospital, July, 1897.
2. Boston Med. and Surg. Jour., Aug. 6, and 13, 1896; Phila. Polyclinic, Sept. 5, 1896.
3. N. Y. Med. Record, Sept. 10, 1892.
4. British Med. Jour., July 3, 1897; New England Med. Mo., March, 1898.
5. Medical Press, Dec. 5, 1888; British Med. Jour., Aug. 29, 1891; London Times, June 27, 1891; and other journals.
6. Medical Brief, June, 1899.
7. Ringer's Therapeutics, pp. 585, 588, 590, 591, 498, 503; The Lancet, London, Nov. 3, 1893.
8. Newcastle Daily Chronicle, Sept. 21, 1888.
9. Med. Press and Cir., March 29, 1899; The Lancet, London, May 6, 1899, p. 1261.
10. Allg. Wiener med. Zeitung, Nos. 50 and 51.
11. Deutsche med. Woch., Nos. 46-48, 1894.
12. Ibid., Feb. 19, 1891.
13. Lecture before Medical Society of Stockholm, Sweden, May 12, 1891.
14. British Med. Jour., *Oct. 15, 1881; Medical Reprints for* May 16, 1893; Nineteenth Century, December, 1895.

For one series of experiments in the above list, those made by Dr. Jansen upon children of the "Foundlings' Home"—with the "kind permission" of the head physician, Professor Medin—because, as he said, "calves were so expensive," it appears that the only authority given was a reference to his lecture delivered before a Swedish medical society upon a certain date. Although, so far as known, the facts there stated have never been denied, yet the reference may, perhaps, be called indefinite. But *one* case is not "many." To what other of the references above given did you refer when you informed the Senate committee that "*Many of them are so vague and indefinite that I could not look them up?*" Had you stated that your library—ample as it is—did not contain, and could not be expected to contain, all of the foreign authorities to which reference was made there would have been nothing to criticize. I must assume, sir, that you have not put forth an aspersion of another's reliability merely to have acknowledgement of the inadequacy of your sources of reference; that the proofs of your statement, covering "*many*" cases, are available, and, in the interest of accuracy, I ask you to produce them.

Second: There is yet another point to which I ask your attention. You made the statement before the Senate committee that in regard to our published account of cases of human vivisection, "*many of them are so vague and indefinite that I could not look them up; but, as to those that I could, some are garbled and inaccurate; not all of them, observe.*"

This, sir, is a most serious charge. You distinctly declared that of the cases personally investigated by yourself, as quoted in the pamphlet on "Human Vivisection," some are "garbled and inaccurate." We deny the charge, and again challenge production of evidence upon which it is made.

A "garbled" quotation is one which, by reason of omission and perversions, is essentially unfair. Sometimes it is a statement from which parts are omitted or transposed for the purpose of conveying a false impression. To omit quotation of parts not directly bearing upon the question for the sake of brevity—this is not "garbling," for all quotations would then be impossible. We assert that in quoting accounts of the cases of human vivisection no omissions of essential facts have been made sufficient to impair the accuracy or fairness of the quotation. Let us put the matter to the test. Point out, if you can, the "some cases" which you found "garbled and inaccurate," and in proof of the charge *quote the omitted sentences or words which, had they been inserted, would cause you and the general public to justify and approve the experiments on human beings which we have so severely condemned.*

Third: You stated, sir, before the Senate committee that only two experiments upon human beings "are alleged to have been done in America." I question, sir, whether that remark is quite in accord with the highest ideals of truth; it is the language of doubt; it seems to signify and imply that even you are aware of no other experiments upon human beings than two cases which are thus "alleged." I am very confident, sir, that you will not venture formally to assert—what you have seemed to imply—that you know of but two experiments upon human beings made in this country and recorded in the medical literature of the United States. There is indeed need of further enlightenment, if the medical profession of this country, so worthily represented by yourself, is ignorant of what has been done by men without pity and without conscience.

Trusting to have response from you at an early date, I am,
Yours most truly, JAMES M. BROWN, President.

DR. KEEN'S REPLY.

1729 Chestnut Street.
PHILADELPHIA, PA., Jan. 21, 1901.

JAMES M. BROWN, ESQ., President American Humane Association, Toledo, Ohio.

Dear Sir:—Your letter of October 4 reached me promptly, but as I then notified you would be the case, very pressing engagements, absence, etc., prevented an earlier reply. Now that I have a little leisure, I can answer your letter and furnish you in detail the proofs for which you ask.

There are two pamphlets, both entitled "Human Vivisection." First, one of thirty pages, "printed for the American Humane Association, 1899;" the other of seven pages, "published by the Humane Society, Washington, D. C.," without date, but from its contents published a little later, as it is chiefly a synopsis of the same instances reported more fully in the

---

* Printed by permission.

37433

larger pamphlet. Hereafter when I speak of "the pamphlet" I mean the larger one, unless I specifically mention the smaller one.

This larger pamphlet consists of two parts: first, (pp. 3-12) a reprint of a portion of "Senate Document No. 78" and the rest of it of various quotations, translations and comments. No name is attached to either part to indicate who is responsible for the accuracy of the references, the translations or the quotations. As the whole is preceded by an open letter signed by the president and secretary of the American Humane Association, and as you refer to the pamphlet as "ours," I presume the association holds itself responsible for such accuracy, especially as you as its new president challenge me for proof.

The pamphlet purports to furnish a reprint of a portion of "Senate Document No. 78," and refers to this document in a way that would lead uninformed readers to suppose that this is a document expressing the sentiments of the United States Senate. It is, therefore, important to call your attention to the fact that Senate Document No. 78 is simply a collection of statements and papers by various persons, printed by order of the Senate, but in no sense expressing the opinions or convictions of that body. The last paper in this document is one on "Human Vivisection," by "A. Tracy."

In two respects "A. Tracy" has a right to complain that the reprint is inaccurate: First, it omits to print the name of the author "A. Tracy." Surely he—or she(?)—should receive whatever credit there is attaching to his work. Secondly, on page 30, line 8, of Senate Document No. 78, I read "A. Tracy's comment. ["This patient, therefore, was scientifically murdered."] This statement the reprint very wisely omits—but there are no indications of the omission. Of this, more hereafter.

Your letter challenges the accuracy of my statements in three particulars: 1. I stated that many of the references in the pamphlet are "vague and indefinite." 2. I said that some of the accounts of the experiments are "garbled and inaccurate." 3. I stated that of the experiments narrated in the pamphlet only two were alleged to have been performed in America.

You will pardon me if I indignantly resent your imputation of untruthfulness in regard to this last statement. You entirely misinterpret my statement, which had no reference to my knowledge or ignorance of any other American experiments. I said that the pamphlet only contained two instances of such experiments which were alleged to have been done in America. These are recorded on pages 4 and 5 of the pamphlet. All the rest were done in Europe, South America, and Hawaii, years before it came into our possession. If you still question the accuracy of my statement and believe that there is a third instance of experiments done in America and described in the pamphlet, point it out by page and paragraph.

Turning to the other two really important matters referred to in your letter, let me again state clearly the question at issue. It is not whether the experiments meet with my approval, but solely whether the reports of them in the pamphlet issued by the American Humane Association are reliable and accurate both as to their sources and substance.

1. MANY OF THE REFERENCES ARE VAGUE AND INDEFINITE.

The references are so vague and indefinite in many cases that the statements and quotations made can not be verified by consulting the originals. The preface of your president and secretary states that "in *each case* the authority is given," and what sort of "authority" do you depend upon? Newspaper medicine and surgery are notoriously inaccurate. I have personally had so much experience and observation of this that I am always certain that at least one-half or more of the statements in newspapers in reference to medical matters are inaccurate, not purposely, but only because the writers are not medical men. Yet you depend for the accuracy of your statements upon newspapers as follows (I follow the inaccurate spelling of foreign names in your pamphlet):

1. The Vienna correspondent of the London Morning Leader, Jan. 26, 1899 (p. 3), of whom more hereafter.
2. The Deutsche Volksblatt, Jan. 25, 1899, (p. 3.)
3. The Washington correspondent of the Boston Transcript Sept. 24, 1897 (p. 9), of whom more hereafter.
4. The N. Y. Independent, Dec. 12, 1895 (p. 11).
5. The London Times, June 27, 1891 (p. 16).
6. The Tagliche Rundschau of Berlin (p. 17); no year, month or day being given.
7. The Vossische Zeitung of Berlin, no year, month or day being given (p. 18).
8. The Vorwartz, no year, month or day being given (p. 18).
9. The Danziger Zeitung, July 23, 1891 (p. 18).
10. The Schlesische Volkszeitung, July 24, 1891 (p. 18).
11. The Hamburger Nachrichten, July, 1891, no day stated (p. 19).
12. A correspondent of the Newcastle (England?) daily Chronicle, Sept. 21, 1888 (p. 22).
13. Dr. R. E. Dudgeon, in the Abolitionist, April 15, 1899 (p. 24).
14. A letter by Dr. Edward Berdoe to the London Chronicle, without year, month, or day (p. 29).

Few of these fourteen newspaper references can be consulted in this country; five of them (Nos. 6, 7, 8, 11, and 14) are impossible of consultation for want of any date whatever.

In no case would I be willing to admit a *newspaper* paragraph, a non-professional and usually unsigned statement—even if correctly quoted—as a sufficient authority for a grave charge against an individual or the profession.

Look for a moment what stuff Senator Gallinger stated at the "Hearing" he had himself caused to be printed. It is published on page 31 of the "Hearing" and on page 3 of the pamphlet. It consists of cable dispatches printed in some newspaper—Senator Gallinger did not even remember its name. The author of the dispatch from London is utterly unknown. The dispatch states that "the Vienna correspondent of the [London] *Morning Leader says*" so and so. Who and how reliable is the Vienna correspondent? He says that "the physicians in the free hospitals of Vienna" do so and so. Who *are the physicians?* In what hospitals were these deeds of darkness done?

And upon such evidence it is seriously proposed to indict the medical profession! Whether these dispatches are "garbled and inaccurate" in their alleged facts who can find out?

If a lawyer tried to convict a man of petty larceny on such testimony, he would be laughed out of court. An yet a senator of the United States and the American Humane Association *actually* adduce such statements as evidences of the gravest charges and spread them broadcast!

I now add six other "vague and indefinite" references not to newspapers.

15. On page 13 there is a quotation from Tertullian. The reference in the foot-note is "Tertullian, De Anima, Vol. ii. pp. 430, 433, Tran., by Holmes." I have compared the quotation with Clark's Edinburgh edition of the Translation of Tertullian by Holmes, the date of the edition being 1870. No such quotation exists on pages 430-433. Possibly it may be that the quotation is from another edition. No edition is named in the pamphlet; another instance of a "vague and indefinite" reference.

16. On page 17 a formal accusation is quoted as made by a Dr. Eugen Leidig against certain surgeons. *No reference whatever to any book or journal is given* by which the accuracy of the quotation can be tested. Is not this again "vague and indefinite?"

17. On page 24 is a reference to a paper by "Professor E. Finger, of Vienna (*Allg. Weiner Med. Zeitung*, Nos. 50 and 51." No year is given, a somewhat essential part of the reference, as there are over forty volumes of this journal, each with the weekly numbers 50 and 51. No such paper by Finger is published in that journal, at least from 1890 to the present time. The reference is quoted from a paper by Dr. R. E. Dudgeon in the *Abolitionist*—an English journal—of April 15, 1899. I have been unable to consult this journal. If Dudgeon gave the year, then the Humane Association pamphlet has misquoted him. If he did not, then both the Association's pamphlet and he have been "vague and indefinite."

18. On page 25 again is a reference to a statement in a "lecture before the Medical Society of Stockholm," by Dr. Jansen, of the Charity Hospital, reporting certain experiments. No reference whatever is given even to a newspaper, much less to any medical journal. As the statement is in quotation marks it *purports* to be the exact words used and ought to have had *some* source to which a reference was possible, especially as the preface of the pamphlet says: "In each

case the authority is given." I am glad to see that in your letter you recognize this as one in which the reference is really inadequate. I *notice*, however, that even in your letter you do not supply this missing reference. You say the facts asserted in the Jansen paragraph have never been denied. Of course not. The first *requisite is to know whether* they are correctly quoted.

Turning now from the larger pamphlet to the smaller one, which was spread broadcast by *house to house distribution* in Washington at the time when the hearing on this matter took place last winter, I find repeated in this a number of the same vague and indefinite references and garbled and inaccurate quotations already or to be described, to which are to be added the following:

19. On page 3, an extract from a *report referring to experiments* upon insane patients is printed in quotation marks. The *only reference is to a* "published report" in 1890 of the "Medical Staff of the Public Insane Asylum in Voralberg, Austria." The librarian of the Surgeon General's office informs me that there are two small insane asylums in the Voralberg, *namely*, at Hall and Valduna. Some reports of the former are in the library and in them *no account* of the experiments referred to can be *found. No reply has* been received to a letter addressed to this asylum as named in the pamphlet and written over a year ago.[1]

20. On the same page is an account of some experiments on bacteria from boils, and the reference is to the "*Deutsches Volksblatt;*" no day, no month, no number, no page, nor even the year is given. If this is not "vague and indefinite," what is?

21. On page 24 there is an account of Kroenig's experiments, to which I shall recur later. No reference *whatever is given* to the source from which the account is taken.

2. SOME OF THE STATEMENTS ARE GARBLED AND INACCURATE.

To be vague and indefinite *in* charges affecting the morals and the reputation not only of individuals, but, in fact, of a whole profession is bad enough, but to make statements that are "garbled and inaccurate" is, as your letter recognizes, a much more serious matter. Let me consider the instances in detail.

1. "Vivisection Experiments *Upon the Insane," pages 4 and* 5: In the following quotation, the words of the original, which *I enclose* in brackets, are omitted. "To these patients the thyroid tablets [each pill representing five grains of the fresh sheep's gland] were administered," etc. This omission is of *moment*, because any one familiar with the administration of thyroid extract knows that the doses used by Dr. Berkley are frequently given to human patients, including the insane, *without producing symptoms dangerous to life*, but on the contrary with benefit. I have myself given such tablets to patients with goiter for weeks together in larger doses than Dr. Berkley used.

In the following paragraph the quotation is garbled *by omitting* the words which *I enclose in brackets*: "Two patients became frenzied and of these one died before the excitement had subsided [the immediate cause of the exitus being an *acute disseminated* tuberculosis]." And again in the next paragraph giving a report of the same case, the pamphlet quotes: "The thyroid extract was now discontinued, but the excitement kept up . . . *for seven weeks, at the end of which time* she died." *One would think* this was the end of the sentence and that she died from the effects of the thyroid tablets. Not at all. The original continues as follows: She died "with the clinical evidences of acute miliary tuberculosis"—galloping consumption. Does this not come within the definition of garbling given in your letter? "A 'garbled' quotation is one which, by reason of omission and perversions, is essentially unfair." To say that *this patient, who actually* died of galloping consumption, died from the effects of the thyroid extract, which had not been given for seven weeks before death, is as absurd as it would be to say she had died from the effects of moderate doses of laudanum given seven weeks before. Yet "A. Tracy's" comment on this case is: "[This patient was, therefore, scientifically murdered]." Your Association mutilates its reprints by wisely omitting this piece of absurdity, though the omission is not indicated. Moreover, *the* pamphlet states: "there is no intimation that the administration of the poisonous substance was *given for any* beneficial purpose to the patients, *for he* took care to select patients *that were probably* incurable." On the contrary, Berkley's original paper expressly states that instead of being incurable, one (Case 1) was cured and another (No. 3) was improved. Besides this, though the pamphlet is dated 1899, it omits all reference to Dr. Berkley's letter to the *British Medical Journal* for October 30, 1897, in reply to your friend Dr. Berdoe, which shows that, as a result of the administration of the thyroid tablets to these eight patients—a well recognized remedy for insanity,[2] not one died from the effects of the drug but that, on the contrary, two of those alleged "incurables" were cured—25 per cent.

In his admirable letter to *Life*—Dec. 6, 1900—Dr. Berkley says: "The purpose for which the article was written was to show to the medical profession that *a certain medicament in common use* was not free from objection, and should not be given in unsuitable cases. In *proper ones the results are* among the most resplendent attained by modern medicine, converting *the drooling* dwarf into an intelligent, well-grown man or woman; or in other instances, as in myxedematous insanity, affording the otherwise hopelessly insane with almost a specific to recover their reason." [*See the addendum at* the end of this letter.]

2. The Cases of Lumbar Puncture by Dr. Wentworth, of Boston, (p. 5): "*Lumbar puncture*," I may remind you, is the simple insertion of a hypodermic needle between the vertebræ into the sheath of the spinal cord, but below the cord itself, to obtain a few drops of the *cerebro-spinal fluid for diagnosis.*

The *pamphlet gives* what is called a "brief abstract" of five *of the* experiments related. The abstracts are indeed brief, so brief as to give a wholly erroneous impression *as to* the causes of the patients' death. The omissions are glaring instances of what the logicians call a *suppressio veri* equivalent to a *suggestio falsi*. Let me point this out in detail.

Case 2. It is correctly quoted that the last puncture (where *there were several* punctures I only give the last date) was made "Feb. 16, on the day of patient's death." The pamphlet fails to add, however, the important fact stated by Dr. Wentworth that the *postmortem* showed *an empyema* [*abscess in* the chest] which had burst into the lung, pneumonia, and inflammation *of* the brain with pus as the cause of death.

Case 3. The pamphlet *correctly says* "puncture Jan. 17, 1896; patient died Jan. 22." What Dr. Wentworth adds is omitted, namely: "No symptoms attended or followed the operation." Moreover, the post-mortem showed that the patient died from the widespread *changes* common *to infantile* wasting.

Case 5. The pamphlet says: "Puncture Feb. 3, 1896; patient died Feb. 4." It omits to state what immediately afterward follows, that the post-mortem showed "primary tuberculosis of the intestines. Double pneumonia," as the causes of death.

Case 6. The pamphlet quotes "Puncture Feb. 1; patient died in convulsions three weeks later." It *neglects to state what* Dr. Wentworth *particularly mentions*, "no reaction on the part *of the patient attended the operation*;" and it also fails to state that the child was seen only once and that the diagnosis then made was tubercular meningitis, which was clearly the cause of the child's death, three weeks later.

Case 7. The pamphlet quotes "Punctured Feb. 27; patient died Feb. 28. It omits the fact that the post-mortem showed that the child died from defective development of the brain and other causes; and that the history showed that the child, *who was 7 months of age*, had "*frequent convulsions, which began* when he was about 3 months old. While in the hospital the convulsions occurred not less than twenty times a day. Oftentimes he had several in an hour."

---

[1] This letter was written by myself and not by the librarian.

[2] I quote the *following* from the eighth edition of Hare's Therapeutics, as to the use of thyroid extract: "In the dose of from 5 to 20 grains (0.35-1.3) three times a day [i. e. 15 to 60 grains a day] according to the degree to which it produces its effects, it has proved of value in acute mania and melancholia, puerperal and climacteric insanities, and in stuporous states with primary dementia." Berkley's maximum dose was 15 grains a day.

The inference from the pamphlet's "brief abstracts" of these cases is clearly, and it seems to me by these omissions was meant to be, that the deaths were due to the lumbar punctures, whereas the evidence is that the deaths were due to other causes and in two instances the operation is expressly stated not to have done any harm. Are not these abstracts "garbled and inaccurate?"

3. On page 7 the pamphlet refers to some experiments on the inoculation of lepers with syphilis, made in Hawaii, but published in the *N. Y. Medical Record* of Sept. 10, 1892. It is stated that the patients "were already suffering from one incurable disease and the object of the experiment was to ascertain whether with another, and even worse disorder, they might not be infected." This statement is incorrect. Most writers recognize only three stages of syphilis, primary, secondary *and tertiary.* The writer of the article in question believed that leprosy was a fourth and final stage of syphilis and not an independent disease. It is a well recognized fact by all scientific writers that a patient suffering from syphilis in any stage is immune to an inoculation of the virus; that is to say, the inoculation will not "take" if he is already a syphilitic. It was for the purpose of determining whether leprosy was a fourth stage of syphilis that the attempt was made. *None of those inoculated took the disease.*

4. Sanarelli's Experiments on the Inoculation of Yellow Fever, page 8: The references here are to the *British Medical Journal* for July 3, 1897, and the *New England Medical Monthly*, March, 1898. The extracts marked with quotation marks are from the *New England Medical Monthly.* Between the first and the second sentences of the quotation there should be some stars to note an omission, but none such appear. The omitted words state that *not* the germs of the disease, but the carefully filtered and sterilized germ-free fluid was used. Besides this and many other minor inaccuracies many of the scientific terms are changed into non-medical terms, which is not objectionable in itself. But such changes and inaccuracies should exclude quotation marks, for when used they mean that the words quoted are the *ipsissima verba* of the author, if in the same language, or an exact translation if from a foreign language.

But this is the least of all. The pamphlet says that the injection produced certain symptoms, among which are mentioned "the jaundice, the delirium, *the final collapse,*" the last three words being in italics in the pamphlet to call special attention to them. In the *British Medical Journal* and in the *New England Medical Monthly* the words "the final" *are not to be found.* We see not a few patients suffering from "jaundice, delirium and collapse" who recover, but when the expression is changed to "the final" collapse it means to every one that the patient died.

Moreover, the end of the quotation is as follows: "I have seen, [the symptoms of yellow fever] unrolled before my eyes thanks to the potent influence of the yellow fever poison made in my laboratory." *This entire sentence does not occur* either in the *British Medical Journal* or in the *New England Medical Monthly.* Whether it is quoted from some other source not indicated, or has been deliberately added, I leave you or "A. Tracy" to explain.

Moreover, immediately afterward, on the authority of the Washington correspondent of the *Boston Transcript,* it is stated: "It is understood that some, if not all, of the persons inoculated died of the disease." and then seven times afterward are repeated "the final collapse," the "unrolling before the eyes," "scientific assassination," "death," and "murder" quoted from a public speech before the American Humane Association. Let us see if these *were* "murders."

In the two references given there is no indication whether any of these patients died or not. How, therefore, "it is understood that some, if not all, of them died," I do not know. *As a matter of fact none of the human beings inoculated by Sanarelli died,* as any one desirous of learning the truth could have ascertained by consulting Sanarelli's original publication reporting his experiments with full details. (*Annali d'Igiene Sperimentale,* 1897, vol. vii, Fascic. iii, pp. 345 and 433.)

What hysterical oratory about "the final collapse," which was not final; "scientific assassination," which did not assassinate; and "murder" of those who were so disobliging as still to live! And this on the authority of the Washington correspondent of the *Boston Transcript,* who the pamphlet assures us is a person "who would seem to be unusually well informed in matters of science!" An excellent example of "newspaper medicine" and a good reason for my refusal to accept it as evidence, especially from other correspondents who may not be as "unusually well informed." May I ask whether "the Vienna correspondent of the London Morning Leader" is also one of those who, in your opinion, is "unusually well informed in matters of science," and whether his testimony is as wholly false as the one under consideration?

5. On page 23, the pamphlet quotes an account of some experiments of Dr. Neisser from the "Medical Press and Circular [England], of March 29, 1899." This is an instance again of misquotation and omission which can scarcely be other than intentional. The last sentence of the first quotation states: "of these eight girls, four developed syphilis." No stars indicate that any words have been omitted. The original reads: "of these eight girls [five were prostitutes, and of these five] four developed syphilis." The words in brackets are entirely *omitted in the pamphlet.*. They make a deal of difference, for what is more probable than that four out of five prostitutes should develop syphilis? Whether it makes any differences or not, however, is at present not the question. The issue is whether the quotation is "garbled and inaccurate." Does it not fulfill another of the definitions of "garbling" given in your letter, viz: "omissions of essential facts . . . . , sufficient to impair the accuracy or fairness of the quotation?"

Moreover the pamphlet's comment upon this case is as follows: "Does the London journal which reports these awful experiments denounce them as a crime against every law of morality? Not at all. It simply says that 'it would be difficult to acquit Dr. Neisser of a large measure of responsibility in respect of the causation of syphilis in these cases!' Could reproof be more gentle?"

Is that really all that the *Medical Press and Circular* "simply says?" On turning to that journal, after the above sentence, which is correctly quoted, the editorial continues thus: "We, however, are less concerned in establishing the culpability of Dr. Neisser than in condemning the spirit which prompted such experiments. All measures, even if novel, which may reasonably be expected to assist in bringing about the recovery of the patient without injury to his health may legitimately be resorted to with the consent of the patient, but measures, whether by drugs or by operation, which have not for direct object the cure of the patient and which may prove inimical to his health or condition, are inadmissible under any circumstances and must expose the perpetrator to professional ostracism and to penal rebuke."

Is "professional ostracism and penal rebuke" a reproof than which nothing could be "more gentle?" If this statement is not "garbled and inaccurate," what do words mean? How could this misrepresentation be otherwise than intentional?

6. On page 24 again, reference is made to the experiments of Menge.[3] The extracts being in quotation marks would purport to be exact translations. This is not the case. The collocation of the paragraphs, also—especially in the smaller pamphlet—is such that it would be supposed even by a careful reader that the babies experimented upon were inoculated with the germs taken "from the pus in the abdominal cavity of a person who had died of peritonitis," without any precautions or preliminary experiments, and that, therefore, these babies were exposed to a fatal infection. This is not true. Four columns of text in the original intervene between the first and the second paragraphs alleged to be quoted, and these detail experiments which proved that the inoculations which he then carried out would almost certainly be harmless. The result showed that he was right, for not the slightest ill effects followed. I have only words of

---

[3] Deutsche medicinishe Wochenschrift, 1894, Nos. 46 to 48.

condemnation for Menge's experiments, but to misrepresent these experiments is scarcely less culpable than to perform them.

7. Then follows a brief account of Kroenig's experiments. The objects of these, the pamphlet says, were "to observe the surest way of *breeding* purulent bacteria." This is not true. On the contrary, his object, like Menge's, was to determine how these bacteria are normally *destroyed* in the part of the body in which the experiments were made. In only a single instance did any ill effects follow, and in this case the inflammation was brief and not dangerous either to life or health. In fact, the very *titles* of these two papers proclaim the destruction of the bacteria and not the surest way of breeding them, as Menge's title reads: "On a quality (Verhalten) of the vaginal secretion in non-pregnant females, which is *hostile* to bacteria," and Kroenig's is on the same peculiarity in pregnant women.

In the comment on these two series of experiments, they are spoken of as inoculations "with loathsome diseases," which would suggest to any one that the patients were successfully inoculated with syphilis or other similar diseases. This was not the case. Only inflammation would follow even had the inoculations been successful.

Moreover, to show the vague looseness of the alleged quotations, the two paragraphs on the experiments of Menge are in quotation marks and are introduced by the words, "He says: The bacteria I used, etc.," as if they were exact continuous translations. "He says" nothing of the kind. Instead of being exact translations, the first paragraph is made up of partly correct and partly incorrect translations from page 891 near the top of the second column and near its middle; and the second paragraph of partly correct and partly incorrect trans*lations from page 907 near the bottom of the first column. No* reference whatever is given to Kroenig's paper either by number, date or page. Is not this "vague and indefinite?" As a matter of fact it is the same journal (No. 43, p. 819) as Menge's paper, but published three weeks earlier.

8. On page 25 is one of the most outrageous instances of garbling, and mistranslation, or worse, which I have ever known to be perpetrated, even in antivivisectionist publications. It relates to observations and experiments of Professor Schreiber, reported in the *Deutsche medicinische Wochenschrift* of Feb. 19, 1891. The subject is introduced with the startling caption: "Inoculations with Tuberculin and Germs of Consumption." In the smaller pamphlet the caption is simply: "Injected Germs of Consumption." What was injected was not the "germs of consumption" at all, but tuberculin, a substance which at the date of Professor Schreiber's publication was engaging the attention of physicians throughout the civilized world as a therapeutic and diagnostic agent. To describe inoculations with tuberculin as "inoculations with the germs of consumption" can be attributed only either to gross ignorance or to wilful disregard of the truth.

In the first paragraph occurs the sentence: "He began with one decimilligram and continued to inject the tuberculin in ever-increasing quantities, until he at last injected as much as 5 centigrams, about 50 times as much as Koch said was the maximum dose for children of 3 to 5 years old." Any fair presentation of these experiments would have included Professor Schreiber's sentence, which he prints in bold-face type: "But even with so large a dose injected at one time, the children showed *no trace of a reaction.*" It would perhaps be too much to expect your society to have indicated on what grounds Professor Schreiber was led to the employment of such large doses, and that his observations demonstrated for young infants an exceptional tolerance of tuberculin, a phenomenon for which there are analogies with other drugs.

But the worst falsification is the succeeding account, in the form of what purports to be an exact translation, of Schreiber's inoculation of a boy with tuberculin. The alleged quotation begins: "I am sorry to say that it is very difficult to obtain subjects for such experiments. There are, of course, plenty of healthy children in consumptive families, but the parents are not always willing to give them up." The words: "I am sorry to say that," and the entire next sentence, "There are, of course, plenty of healthy children," etc., *are not in the original, but are additions made out of the whole cloth.* The next following sentences contain many inaccuracies, such as the translation of the German words *beträchtlich anschwollen* as "swelled up enormously," instead of "swelled up considerably." But the worst is the deliberate insertion of the following sentence, italicized in the pamphlet, *which also does not occur in the original:* "I can not yet say whether the boy will be consumptive in consequence of my treatment." The correct translation of Schreiber's words at the point where this closing sentence appears in the pamphlet is as follows: "I could discover no other alterations in the otherwise apparently healthy boy." [*Andere Veränderungen konnte ich an dem sonst gesund scheinenden Knaben nicht entdecken."*]

While I have said enough about this case to substantiate my charge of garbling and inaccuracy, I can not refrain from utilizing it also to show the utter misapprehension which the citation of detached sentences and paragraphs from medical articles is calculated to create in the mind of a non-medical reader. Even when the words are quoted correctly, they are likely, when detached from the context, to give rise to entirely false impressions. This is a criticism which applies not only to other examples cited in this pamphlet, but to a very large number of reports of experiments and of quotations from medical journals and books current in anti-vivisectionist writings, and the resulting dissemination of erroneous conceptions is often greater even than that caused by inaccurate or garbled quotations. A brief explanation of the present example will show the justification of this charge.

For what purpose did Professor Schreiber inoculate the boy with tuberculin? His article leaves no doubt as to the answer. He points out the importance of the earliest possible recognition of tuberculosis in a patient in order to secure the best curative results. The boy's mother had consumption and the author calls attention to the frequency of unrecognized tuberculosis in the offspring of tuberculous parents. The boy received a small dose—1 milligram—of tuberculin, which, if he were free from tuberculosis would produce no effect but which if he had unsuspected tuberculosis would produce a transient—though possibly a severe—fever, and a local reaction indicative of tuberculosis. Such reaction followed the injection of tuberculin, and the diagnosis of tuberculosis, which had not been, and very likely could not have been, made in any other way, was established. I do not know what could have been more fortunate for this boy than the recognition in its incipiency of a disease previously unsuspected and which, recognized thus early, should in all probability be cured by proper treatment. This tuberculin test is constantly employed to prevent the spread of tuberculosis in our cattle. In our children it enables us to discover the same disease in an early, curable stage. Shall we care for our cattle better than for our children?

Its use is not properly to be called an "experiment" at all. As I write this, I find in the Journal of the American Medical Association for Jan. 12, 1901, page 75, three cases of the use of tuberculin in human beings by Prof. J. M. Anders, who points out its value in enabling us to diagnosticate consumption "in latent forms and dubious cases, however incipient," long before percussion or the stethoscope will reveal the disease. I can imagine his surprise if he were charged with making three horribly cruel "experiments" and injecting the "germs of consumption!"

It is euphemism to call such an alleged quotation, in which words and one entire sentence are interpolated and another wholly changed in meaning, a "mistranslation" or even a "garbled and inaccurate" account. Does it not amount to literary forgery? It is another illustration of the fact that when an anti-vivisectionist attempts to say anything about scientific experiments either the moral sense is blunted or the truth-telling faculty is in abeyance. A good English example is the misstatements in Miss Frances Power Cobbe's book, laid bare by Victor Horsley, and Schreiber's and Sanarelli's cases will serve as excellent examples of American misrepresentation—if so long a word is needed to describe them.

I am sorry my reply is so long, but in fewer words I could not explain the many and gross errors to be pointed out. I have given you indeed "many" instances in which the references are "vague and inaccurate," and "some" in which the accounts are "garbled and inaccurate." These adjectives are, I submit, very mild ones to apply to such a pamphlet.

You can hardly be surprised after the extraordinary and repeated interpolations, mistranslations and worse which I have demonstrated in this letter that I am unwilling to accept *any* alleged quotation or translation emanating from the American Humane Association as accurate and truthful unless I can compare it with the source from which it is derived.

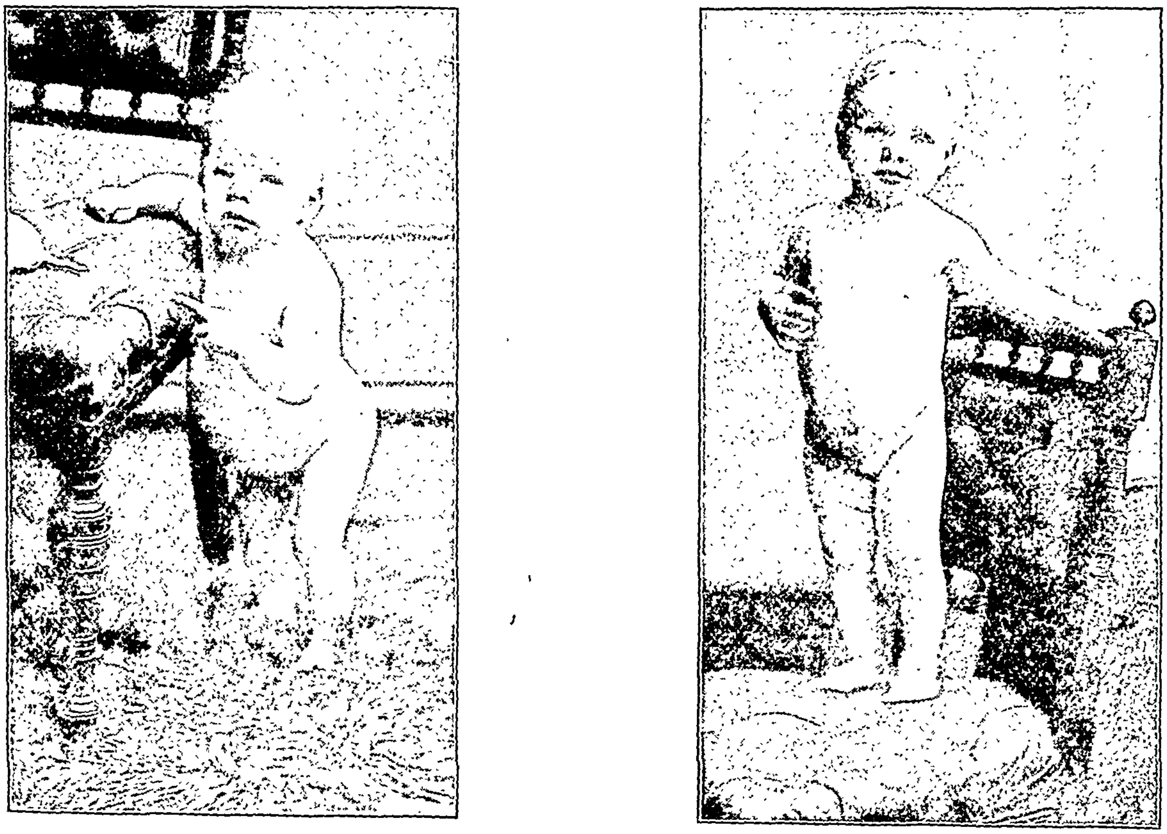
In conclusion let me commend to the "Humane" Association the closing words of President Eliot's letter, to be found on pages 218-9 of the "Hearing": "Any attempt to interfere with the necessary processes of medical investigation is, in my judgment, in the highest degree inexpedient and is fundamentally inhuman."

I shall take the liberty of publishing my reply. I suppose that you will not object to the publication of your letter with it in order to explain the reason for the reply.

Very respectfully yours, William W. Keen, M.D.

ADDENDUM.

Since this letter was written I have seen an article in "Gould's Year Book of Medicine and Surgery," 1901 (Medical Volume, p. 327), from the *Archives of Pediatrics* for June, 1900, p. 431, by H. Oliphant Nicholson of Edinburgh, Scotland, reporting the case of Annie C., a girl of 2 years and 8 months old, with pictures (see plate), which, with a brief statement of the case, well illustrates what Dr. Berkley has asserted, that "in proper cases, the results [of the treatment by thyroid extract] are among the most resplendent attained by modern medicine, converting the drooling dwarf into an intelligent, well-grown man or woman."



Illustrating Nicholson's article on thyroid treatment in a cretin (Arch. of Ped., June, 1900). Result of four months' use of thyroid extract.

This child was first seen by Dr. Nicholson on October 23, 1894, and the picture shows the "swollen, myxedematous-looking face and body, a markedly curved back and a pendulous abdomen." The child "could not walk without support and dragged her limbs slowly after her." Her vocabulary was confined to calling her mother and father "mum" and "ah," and "her wishes were wholly made evident by signs." Very naturally, therefore, with this low grade of intelligence, she was uncleanly in her habits.

The treatment was begun on October 30, with 2.5 grains of thyroid powder, once daily. This was reduced on November 2 to 1.25 grains once a day, and was continued for several weeks. As early as November 7, improvement was noticed. On November 17 the pulse at the wrist, which was scarcely perceptible through the swollen tissues at the beginning of the treatment, was distinctly felt, and by the 24th, the puffiness of the eyelids and forehead were diminishing and the expression of the face becoming more intelligent. The dose of the extract was now increased again to 2.5 grains. The results I quote as follows: "In about three months' time very few traces of cretinism remained and the child was able to walk about easily without assistance and was making use of the short words and gestures of early childhood. . . . After four months of the thyroid treatment, the improvement seemed so complete that the second photograph was taken and the likeness produced is that of a bright, happy, pretty child, to all appearances normal, both physically and mentally. The improvement continued till the middle of June, 1895, when, unfortunately, she contracted an attack of malignant measles and died on July 16, after three days' illness."

If Dr. Berkley's use of the thyroid extract, which cured two out of eight patients was an experiment, and its administration by Dr. Nicholson also was an experiment, the more of such happy "experiments" we could have, the better.

Tuberculosis Among Postoffice Employees.—The French statistics recently published indicate that tuberculosis is much more prevalent among the picked indoor employees of the post and telegraph service than in the general population, reaching 62 per 10,000, while the general mortality from tuberculosis at Paris is only 49 per 10,000. Tubercular affections represent 15.45 per cent. of the total mortality among the indoor employees, and 10 per cent. among those employed out of doors. Stricter regulations are to be enforced, according to a notice in the *Semaine Méd.* Each employee is to have "a health book" and at the first indications of a tubercular affecton is to be sent to a special sanitarium.

ANASTOMOSIS OF THE URETERS WITH THE INTESTINE.

A HISTORICAL AND EXPERIMENTAL RESEARCH.

REUBEN PETERSON, M.D.
Professor of Gynecology Post-Graduate Medical School; Assistant Clinical Professor of Gynecology, Rush Medical College; President of the Chicago Gynecological Society.
CHICAGO.

(Continued from page 445.)

Morestin,[14] 1893. *Twenty-four dogs; ten bilateral, fourteen unilateral implantations; all died, except one, of peritonitis, nephritis, or hydronephrosis; survivor died several weeks later of hydronephrosis and infection.* Morestin experimented on twenty-four dogs with a view of uniting the ureters with the rectum. In ten cases a bilateral implantation was made. The method employed in six cases was to whip-stitch the intestinal mucosa about the ureter after the latter had been thrust into the rectum. The six animals died of peritonitis or ascending renal infection. In four cases the ureteral mucosa was sutured to the rectum. Of these, two died of infective peritonitis and two from uremia from compression of the ureters. In fourteen dogs unilateral implantation was tried, four times without and ten times with preliminary dilatation of the ureter by the application of temporary ligature. The first four animals died from peritonitis. In four cases where simple dilatation was practiced, three died of peritonitis, and one lived several weeks and died from hydronephrosis and infection. In the six remaining dogs, after previous dilatation, the ureter was sutured to the rectum laterally. All died from hydronephrosis or infection.

Morestin's conclusions are that bilateral implantation of the ureters into the rectum is entirely inadmissible, and single implantation only admissible in extreme cases. The primary *mortality in man should be less than in animals, because of* the larger size of the ureters and the possibility of securing better asepsis.

Thompson,[21] 1893. *Number of implantations not stated; one dog survived; after three weeks ureter and pelvis of kidney markedly dilated.* Thompson makes a brief mention of a successful implantation of the ureter into the small bowel. The exact method employed is not stated. The post-mortem at the end of three weeks showed the uretero-rectal union good, the ureteral orifice patent, but the ureter and pelvis of the kidney markedly dilated.

The hydronephrosis was ascribed in part to the stenosis and partly to the mobility of the intestine. The attempts to unite the ureter with the colon or rectum were failures.

Giordano,[6] 1894. *Sixteen dogs, three survived; pyelonephrosis; uretero-rectal stenosis.* Giordano, in order to do away with the dangers of implantation of the ureters into the bowel by the intraperitoneal route from his experiments on animals and cadavers, proposed the removal of a portion of the sacrum and an extraperitoneal route. In 1894 he published in detail a series of experiments in sixteen dogs, where the ureters had been implanted into the bowel extraperitoneally by lumbar incisions or through the sacral region. No microscopic or bacteriologic examinations of the specimens were made, and the descriptions of the gross specimens are exceedingly vague.

Out of sixteen dogs only three lived more than a week. In one case both ureters were implanted in the colon by lumbodorsal incisions. Death on third day; obstruction in left ureter; both kidneys congested.

In three cases this same operation was performed in two stages, first one and then the other ureter being implanted. One dog died from anesthetic at second operation, seven days after the first; ureter normal; kidney not enlarged.

The two other dogs lived one hundred and twenty-one and eighty-four days. The post-mortems revealed uretero-cutaneous fistulæ in both, associated with dilatation of the pelves of the kidneys, stenosis of the ureteral orifice and pyelonephritis.

In eight instances both ureters were implanted into the rectum. Of these, five died of peritonitis or sepsis, with congestion of the kidneys. One dog died from hemorrhage from the anus. In this case tubes had been used in the ureters. One animal lived seventy-seven days; autopsy showed fluid in abdominal cavity, due to intraperitoneal rupture of kidney abscess, other kidney being of normal size. In three cases the ureters were implanted in the rectum with the formation of an artificial anus; wounds were always infected and kidney congestion marked.

Giordano's conclusions are: that if the ureters are not obstructed there does not necessarily follow any infection of the kidneys. It is best to implant the ureters extraperitoneally and at two sittings.

Van Hook,[24] 1893. *Sixteen dogs; seven recoveries; two with one ureter in small intestine; pyelonephritis and uretero-rectal stenosis; five with one ureter in rectum; pyelonephritis in each case; uretero-rectal stenosis.* Van Hook implanted a single or both ureters into the small or large intestine in sixteen dogs. This experimenter's primary mortality has not been equalled before or since. This fact, together with the accuracy with which the post-mortem findings are recorded, warrants a careful study of his cases.

The following method of implantation was employed: After isolating the ureter with an ample fold of the peritoneum, it is severed and its end split upward with scissors a short distance. Two small needles armed with a single fine silk or catgut thread are passed from within outward through the split end of the ureter. The two needles are now carried downward through a small slit in the bowel and made to penetrate the bowel one-half inch below the point of entrance. The ends of the thread are tied, retaining the ureter in place. The knot is covered with Lembert sutures and the bowel opening closed as tightly as possible without compressing the ureters.

In two dogs a single ureter was implanted in the small intestine, eighteen inches above the ileocecal valve. Both recovered and were killed ten days later. The kidneys corresponding to the implanted ureters were found smaller and showed pyelonephritis. The opening into the bowel in both instances was somewhat stenosed and there were two drams of purulent fluid in the pelvis of the kidney and ureter.

In eight dogs one ureter was implanted into the rectum, with three deaths. Corresponding kidneys violently inflamed, being swollen, turgid and heavy, with muco-pus on the mucous membrane of the pelvis. Pelvis of the kidney, opened with a red-hot knife, contained a few drops of mucopurulent fluid. Uretero-rectal orifice patent. Microscopic examination showed violent hemorrhagic inflammation of the pelvis and pyramids of the kidney. Cultures showed numerous bacteria.

Five dogs recovered, and were killed from fourteen to twenty-one days after the operation. In three dogs, kidney corresponding to implanted ureters showed suppurative inflammation. Only the smallest probe could be made to pass the rectal opening.

In six dogs both ureters were implanted into the rectum. All died within six days. Four deaths due to general peritonitis. In two cases there was obstruction of the ureter and retention of urine in the pelves of the kidneys. Conclusions are that implantation of one of both ureters into the rectum is absolutely unjustifiable under all circumstances, because: 1, the primary risk is too great; 2, there is great liability to stenosis of the duct at the point of implantation; 3, suppurative uretero-pyelonephritis is almost absolutely certain to occur either immediately or after the absence of months or years.

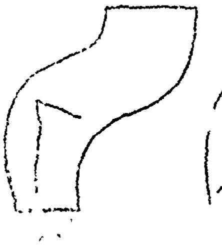
Chaput,[3] 1894. *Numerous dogs; number not stated; all died.* Chaput performed many experiments on dogs, making use of a great variety of methods in his attempts to anastomose the ureters with the rectum. His efforts were entirely unsuccessful. He ascribes his failures to the small size of the dog's ureter and to the great rigidity of the intestinal walls, causing the sutures to cut through and rendering union almost impossible. He thought that experiments on dogs would prove of but little value in determining the effects of ureteral anastomosis in man, as the bacterial contents of the dog's intestine were much more virulent and consequently more liable to give rise to serious lesions in the ureters and kidneys.

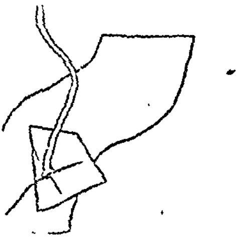
Mauclaire,[15] 1895. *Number of dogs not stated; upper part of rectum cut off and ureters implanted therein; all died.* Mauclaire, in order to avoid ascending infection when the ureters are implanted in the rectum for the cure of exstrophy of the bladder, amputated the rectum and inserted the ureters in its upper part after first establishing an artificial anus in the inguinal region. All the animals died of infection from the intestinal resection or from uremia resulting from the uretero-rectal implantation. For fear of leakage, he advises extraperitoneal implantation. While he was obliged, in dogs, to make the artificial anus in the inguinal region, his studies of the cadavers of young children have shown that the superior intestinal fragment can be brought down into the pelvis and the artificial anus established in the left ischio-rectal region.

Vignoni,[25] 1895. *Seven dogs, with one recovery; V-shaped flap; no report of findings.* Vignoni performed seven experiments on dogs, and succeeded in making only one live more than two months with one ureter in the rectum. He made use of a V-shaped flap cut out of the anterior wall of the bowel; after placing the ureters on this flap, the former are covered by suturing over them the lateral folds of the bowel wall. From these experiments Vignoni concludes that it is advisable to implant one or both ureters into the rectum for certain conditions.

Lindner,[11] 1895. *Number of dogs not stated; implantation into transverse colon, with satisfactory results.* Lindner, in a discussion of Trendelenburg's case of removal of the bladder, mentioned that in a series of experiments made a few years before on very large dogs, he had transplanted the ureters into the transverse colon and found that the urine passed per anum n a very satisfactory manner. The dangers of infection are ncreased when both ureters are implanted, and in order that he ureters may not pull out it is advisable to retain a portion f the bladder wall.

Kryński,[9] 1896. *Numerous dogs, number not stated; uretero-ctal stenosis, hydronephrosis, and infection; by new method ll recover.* Kryñski states he has proved that infection of he kidneys, stenosis of the ureteral orifices, and hydronephrosis will result from implantation of the ureters into the intestine by the usual methods. He then describes an operation, by following which he has never seen a single case of disease of the ureters or kidneys.





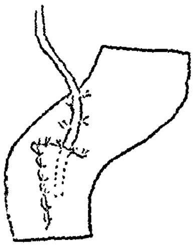


Fig. 3.

A triangular incision is made (Figs. 1, 2 and 3) through the serosa and muscle on the anterior inner margin of the gut just below the sigmoid flexure. The longest side of this triangle is 2.5 to 3 cm. in length; the shortest, 1 cm. A small incision is made in the mucosa at the apex of the triangle. The ureter is cut off obliquely, and is united to this incision by four interrupted sutures joining the rectal to the ureteral mucosa. The triangular flap is now sewed over the implanted ureter, a continuous suture being used for the long side and interrupted sutures for the short side. Too tight sewing of the triangular flap will produce an obstruction of the ureters.

Pisani,[18] 1896. *Two dogs; both died; collapse and peritonitis.* Pisani performed the following operation on two dogs: The abdomen was opened and a rectangular flap removed from the bladder, containing the ureteral orifices. The rectum was now isolated and an incision 3 to 4 cm. long made in its anterior wall. A portion of the posterior rectal mucosa corresponding to the bladder flap was freshened, and to this was sutured the flap containing the ureteral orifices. The anterior rectal wall was now sutured and the abdomen closed.

One dog died in sixty-two hours. Collapse and obstruction assigned as causes of death. Ureters not dilated. The flaps were united; kidneys normal; urine evacuated easily through rectum. The second animal died of septic peritonitis, caused by rupture of the abdominal wound. Evacuation of urine satisfactory; no dilatation of ureters.

Boari,[2] 1896. *Four dogs; four recoveries; two still living; in two dogs kidneys macroscopically normal.* (?) Boari, by means of his anastomotic button, succeeded in uniting the ureters to the rectum in two dogs. The first animal lived fifty-two days after the left ureteral implantation and fifteen days after the right. The ureters were not dilated. The right ureteral opening was surrounded by a small papilla-like valve. The kidneys macroscopically showed no grave lesions. There was no hydronephrosis, although the pelvis of the right kidney was slightly dilated. The second dog was killed thirty-two days after the implantation of the right ureter into the rectum. The macroscopic appearance of the kidney was normal and the pelvis of the kidney was not dilated. Two more animals had been operated on successfully, and were still alive at the time of the report.

Lestrade,[10] 1898. This experimenter implanted the ureters into the rectum in four dogs, using Chalot's anastomotic button, but the animals all died of sloughing of the sutures and escape of urine into the peritoneal cavity.

Martin,[12] 1899: *Forty-two dogs, five recoveries; pyelonephritis; numerous bacteria in kidneys; chronic interstitial nephritis.* Martin presented before the Chicago Gynecological Society the specimens and post-mortem findings from three dogs where the ureters had been implanted in the rectum. The animals had lived four, eleven and ten months, respectively, after the operations. In one case both and in another a single ureter was implanted in the rectum. In the third dog one ureter was implanted in the jejunum eight and one-half inches from the pyloric orifice. The rectum acted as a perfect substitute for the bladder in all cases.

The post-mortem showed marked changes in the kidneys corresponding to the implanted ureters. There were evidences of an active pyelonephritis in two dogs, as shown by the presence of purulent fluid and numerous bacteria. In one dog a very few coli bacilli and diplococci were found in the pelvis of the kidney. The kidney was smaller than the other and presented interstitial changes, resulting from an old pyelonephritis. Thirty-four dogs were operated on and only three survived. The implantation was made perpendicularly to the axis of the intestine.

The author publishes in the same month a new method of implantation of the ureters, having for its object the making of subsequent infection of the ureters and kidneys impossible. The ureters are buried in the walls of the rectum for a distance of an inch or more longitudinally, so that the ureters may be milked downward by the contraction of the bowel-muscles artificially surrounding the ureters. The ureters are dissected away from the peritoneum for three inches by the finger. Longitudinal incision, two inches in length, is now made in the peritoneal and subperitoneal tissue of the bowel. The remaining coats of the bowel are opened by a small incision, through which are passed two needles, to which are attached silk ligatures passed through the coats of the bowel below the incision and the ureters made taut and attached to the fibrous and muscular coat by silk sutures, care being taken not to penetrate more than the fibrous coat of the ureters. The peritoneum is now closed about the ureters by a continuous suture.

Dr. F. R. Zeits' examination of a dog operated on three months previously by this method showed both ureters patent: suppurative nephritis existed in the right kidney; pelvis normal; bacteriologic examination negative. Left kidney shows chronic interstitial nephritis; capsule slightly adherent; pelvis normal. Bacteriologic examination of right kidney showed coli communis present; none in the left.

Matas,[13] 1899: *Four dogs—two with Boari button and two Maydl's operation—all died; first two, renal infection; last two, peritonitis.* Matas employed Boari's technique in two dogs and united the intestine to the ureters, but the dogs died from acute ascending renal infection. In two dogs in which the Maydl operation was tried, one died in twenty-four, the other in thirty-six hours. In both the vesico-ureteral grafts were perfect. In both there was septic peritonitis, caused by infection from the bowel at the time of the operation, and in the dog that survived thirty-six hours there was also intense hyperemia of the kidney.

Kalabin,[8] 1899. *Thirteen dogs; Maydl's operation five times, five deaths; one dog survived one month; kidneys normal; ureteral orifices patent; one survived thirteen months: showed interstitial nephritis.* Kalabin, to verify Morestin's experiments of implantation of the ureters into the rectum, experimented on thirteen dogs. Maydl's operation was performed on five dogs; three died of peritonitis, two of uremia.

In four dogs he implanted a single ureter into the rectum. Three of the four died; two of peritonitis, one of uremia. The fourth dog lived a month; post-mortem showed kidneys *normal*. In four other dogs where a single ureter was implanted in rectum, two died of peritonitis and one of uremia; one dog survived thirteen months. The kidneys showed an interstital nephritis. The ureter and rectal mucous membrane were normal.

Frank,[5] 1900: *Uretero-rectal anastomoses; number of dogs not stated; infection in every case; vesico-rectal anastomosis with Frank coupler, fifteen dogs, ten recoveries; five post-mortems show but slight changes in kidneys.* From his experiments on implantation of the ureters into the rectum, Frank's conclusions were that infection of the kidney supervenes in every case and that no better results could be looked for in the human being. In order to preserve the ureteral orifice intact and thereby prevent an ascending kidney infection, Frank, by means of his bone coupler, made a communication between the bladder and the rectum in fifteen dogs, with ten recoveries. For a week after the operation urine and feces were voided oftener than after this period. The feces are always passed in a liquid form, being softened by the urine. Two dogs operated on six months previously are alive and well. In the five dogs in which post-mortem findings are reported, two show colon bacilli in the kidneys; one is not free from bacteria, but they are neither colon bacilli nor staphylococci; two cases show histologic changes in the form of round-celled infiltration. In one case the left kidney is noted as congested and the ureter enlarged to double its normal size.

Frank's conclusions are that the recovery of the dog and the macroscopic appearance of the tissues do not necessarily signify absence of infection; that the dogs killed thus far show that the operation of vesico-rectal anastomosis can be performed without a resulting kidney infection.

SATURDAY, FEBRUARY 23, 1901.

YELLOW FEVER AND ITS TRANSMISSION.

The results of the experiments of Drs. Reed, Carroll and Agramonte, as published in our last issue, are certainly remarkable and convincing. That yellow fever is transmissible by the mosquito is proved, and that our previously-held theories of its propagation must be amended can not be denied. Some even hold that it leaves us nothing to do in the way of quarantine and disinfection, and this view is largely taken at once, offhand, by the lay press generally, and by some of the members of the medical profession. These seem to have at once assumed that the questions are settled and that the quarantine precautions of the past have been useless and can be dispensed with in the future. The problem of yellow fever is held by them to have been solved.

This we feel assured is not the conclusion that the more conservative authorities will admit. The results were most striking and must assuredly throw a doubt upon all former theories of infection, etc., but any one accustomed to weighing evidence must acknowledge that much yet remains to be demonstrated before we can positively say that the disease is not transmitted in other ways than those indicated by the experimenters. The comparison with the malaria discoveries, which themselves still lack something of absolute completeness, is not entirely applicable. We know the malarial organism and to a great extent its life history, though there are yet some points requiring knowledge. The germ of yellow fever, however, is still in dispute and these investigations themselves oppose the validity of the only organism heretofore recognized as such. Not knowing even the existence of the germ except by justifiable inference, we know nothing of its peculiarities except that it appears, like the malaria germ, to be transmitted by mosquitoes and to require a certain period for its life cycle. As far as the investigations have been reported, it does not seem positively proved that it has for its host any one exclusive form of mosquito, and there are yet variances between the views of such an experienced clinical observer as Dr. Finlay, the originator of the mosquito-transmission theory, and the findings of the experimenters. There is a close resemblance in method and results between these experiments and those of Drs. Sambon and Lowe on malarial transmission, but the latter only finished off in full the chain of facts that led almost inevitably to the conclusions they demonstrated.

Admitting, however, as it seems probable we shall be compelled to do, that the mosquito-borne theory of yellow fever transmission is correct, it does not necessarily follow that all the former precautions are useless or even that there may not be other methods of introduction of the infection into the human system. The experiments with fomites appear to be almost, if not absolutely, conclusive, but conditions might occur that were not realized in these experiments. We have to consider the fact that the subjects of experimentation were men in good general health, and their morale and the psychic surroundings, so to speak, were of the best character to make them resistant to contagion. This last—the psychic element—is one that is not to be slighted, as clinical experience has amply proved on numerous occasions.

The utility of disinfection, if not of quarantine, has been repeatedly demonstrated; if ships, cargoes, and fruits can not convey the germs in a way to be directly dangerous, they can none the less convey the infected mosquitoes. These insects, as is well known, are often carried long distances by public conveyances, and this is very probably the origin of many local outbreaks of yellow fever, hitherto attributed solely to fomites.

The experiments of Drs. Reed, Carroll and Agramonte mark a great advance in our knowledge of yellow fever, and we do not in the least discredit them. For them to be accepted as conclusive, however, and as overthrowing at once all former notions, is not exactly the scientific course; they point the way to other observations which must be chiefly clinical and confirmatory. The organic cause of yellow fever must be sought out and its life history determined. The facts already obtained must guide us to others, but though it seems to us probable that all the apparent consequences of these experiments may yet have to be accepted, in the meanwhile it would be foolish to think of neglecting all hitherto accepted safeguards against the disease, as some are intimating should be done.

A PLEA FOR ADEQUATE DOSAGE OF ANTITOXIN IN THE TREATMENT OF DIPHTHERIA.

It seems like a repetition of ancient history to dwell at this day upon the life-saving power of diphtheria antitoxin and to cite statistics showing the reduction in mortality that has been effected by its employment. The time has passed when there can be any difference of opinion on these points. One feature, however, can, it seems, be profitably discussed, inasmuch as the antitoxin is not universally administered in doses capable of yielding the maximum beneficial effects, partly as a result of a not unnatural conservatism and partly from the want hitherto of comparative data of convincing value. From a number of sources the recommendation has of late been made for the employment of larger doses of antitoxin than has been customary, especially as the agent is capable only of good, and no seriously ill consequences can be attributed to its action. For those who may have felt any doubt in this connection the publication, recently, by Dr. J. H. McCollom,[1] of the statistics for the South Department, a hospital opened in Boston in 1895, for the treatment of cases of diphtheria exclusively, must bring conviction.

It appears that since a record of cases was begun in 1878, Boston has suffered more from the inroads of diphtheria than any other large American city. Although a marked reduction in the mortality has been effected in recent years, the number of deaths from this disease in 1894 was 817, and in 1898, 170. The case-mortality has ranged from 35.7 per cent. in 1881 to 9.76 per cent. in 1899, and the disease in the latter year was of an extremely virulent type. While the ratio of mortality from diphtheria, for 10,000 of the living in Boston, in 1893 was more than 11 and in 1894 more than 19—being higher than in London, Liverpool, Glasgow and Paris, as well as New York, Philadelphia, Brooklyn, Chicago and St. Louis—by 1898 it had fallen to 3, and in 1899 it was 4.9, as low as in some and lower than in others of the cities named. This reduction coincides with the opening of South Department in 1895, when every case of diphtheria admitted was treated with the antitoxin. Prior to this year only about 10 per cent. of the reported cases were treated in hospitals, while in succeeding years 50 per cent. were so treated.

The excessive prevalence of diphtheria in Boston is shown by the fact that the ratio of morbidity in 1895 was 81, and in 1899, 51; while in Glasgow it was in 1898 only 5.9, in London 25.62, in New York 37.06, and in 1899 in New York 38.77. With the reduction in the morbidity ratio in Boston there has been also a reduction in the mortality ratio per 10,000, from 11.73 in 1895 to 4.99 in 1899, and in the case-mortality, from 14.48 per cent. in 1895 to 9.76 in 1899. Prior to 1895 the mortality rate from diphtheria in the Boston City Hospital was 46 per cent., while in the five years that the South Department has been in operation—and 7657 cases were treated—the mortality has been 12.09 per cent. Of this number 772, or 10 per cent., required operative intervention. In 100 others, marked laryngeal symptoms were present, but the stenosis was relieved by the antitoxin. The mortality in cases requiring intubation was 34 per cent. This is due in part to the fact that the serum was administered in large doses when there was any indication that the membrane was extending into the bronchi.

The guiding rule in the administration of the serum is that it must be given until the characteristic effects are produced, namely, shriveling of the membrane, diminution in nasal discharge, correction of fetid odor and general improvement in the condition of the patient, whether 4000 or 70,000 units be required. The injunction is laid down that no case of diphtheria in the acute stage should be considered hopeless, but antitoxin should unconditionally be administered. In illustration of the advantage of the early administration of antitoxin, it is pointed out that, since September, 1895, there have been 101 cases of diphtheria among the staff of South Department, contracted in the line of duty, without a single death. Each patient received a full dose of 4000 units at the outset, or as soon as there were any symptoms of the disease. In some instances it was not necessary to repeat the dose, while in others it was repeated two or three times. In none was there any marked paralysis or any heart complication, and the duration of the illness was comparatively short. Altogether, small doses of antitoxin proved of little avail in the treatment of grave cases, but the best results were yielded by heroic doses. When death occurred it was due to nerve degeneration or septicemia. In no instance was any injurious effect produced by either large or small doses of the antitoxin.

In view of all of the evidence there can no longer be any excuse for failure to administer the antitoxin in every case of diphtheria, mild or grave, and the earlier the better, in dosage sufficient to bring about the desired result.

SCIENTIFIC USE OF HOSPITALS.

Sir Michael Foster discourses upon this interesting topic in a recent magazine article.[1] While much that is already known must be learned by the medical student. there remains a vast extent of unknown that must be learned before the healing art may gain the mastery of disease desired so much by all. Our hospitals offer great opportunities for gathering new truths, but unfortunately adequate use is not made of these opportunities, not only in England but also in this country, and quite likely elsewhere as well. Sir Michael Foster meets the constantly recurring agitation against hospitals being used for the purposes of experiment—which is the favorite phrase of those misdirected persons who hold that hospitals ought not to serve for advancing knowledge—by pointing out that every sick person who seeks medical aid makes himself the subject of an investigation, that no physician or surgeon is ever absolutely sure of the result of his act, while the knowledge gained by the result thereof is always made of use to others.

Thus every hospital and every doctor's office becomes the daily scene of a continued series of experiments, each for the special and immediate benefit of the patient who is subjected to them. And rightly used this newly gained knowledge makes for the welfare of succeeding patients, each increment of knowledge meaning decrement of human suffering. The welfare of the individual patient and the advancement of knowledge go hand in hand. Looking at the daily work of a hospital in this broad way, is not Sir Michael Foster in the right when he ventures the criticism that the analysis of the phenomena observed at the bedside and in the laboratory is only too often not so exact, so complete and so systematic as it ought to be?

---

[1] Boston Med. and Surg. Jour., 1900, No. 25, p. 627.

[1] The Nineteenth Century and After, January, 1901, 57-63.

Such analysis demands the use of exact methods and of the instruments of precision of physics, chemistry, and biology.

A few test-tubes, an alcohol lamp, and a microscope are no longer adequate for the exact and complete analysis of the phenomena of disease, which now requires clinical and other laboratories fully equipped with a variety of appliances. These laboratories are distinct from educational laboratories because they are to be used for the direct and special benefit of the patients. A complete study and analysis of this character may be of great use in determining facts of signal importance as regards the nature of the patient's disease; data may accumulate for the purpose of subsequent inquiry and study; but the highest value of the results of proper analysis lies in their use to throw light on the nature of disease. This means the institution of a series of inquiries with definite ends in view. Every surgeon and every physician, from the chief down to the lowest grade, should be animated by the spirit of inquiry and research; even then but a fraction of the problems presented could be properly handled. "The harvest of truth is plentiful, but the laborers are few."

Sir Michael Foster's assertion that the great hospitals of London are behindhand in equipment and in the kind of work that advance medical knowledge is true when applied to most of our own hospitals as measured with his standard even though it was what he heard on this side of the water during his recent stay here that led to the thoughts put forth in this article! The organization of the majority of our large hospitals is utterly inadequate to make scientific use of the opportunities offered for advancing medical knowledge. A hospital with its wards and its scientific equipment is in reality a great medical laboratory whose duty it is to heal the sick and to increase knowledge, the two being inseparable. It may confidently be asserted that where the second duty is not or can not be performed properly, there the first also suffers neglect.

THE ARMY MEDICAL SERVICE.

Under the army reorganization act, which has now become a law, the medical corps is enlarged from a total of 192 to 321 medical officers, including the surgeon-general with the rank of brigadier general, 8 assistant surgeon-generals with the rank of colonel, 12 deputy surgeon-generals with the rank of lieutenant-colonel, 60 surgeons with the rank of major, and 240 assistant surgeons with the rank of first lieutenant, mounted, for the first five years, and the rank of captain, mounted, thereafter until promoted to major. There are now, therefore, 129 original vacancies in the corps of assistant surgeons, and the war department has published a circular of information for candidates seeking these positions, which can be obtained by application to the Surgeon-General of the Army, Washington, D. C. The examinations, which will be held at an early day, are both physical and professional. Candidates must be citizens of the United States, between the ages of 22 and 29, except in cases where they have served honorably in the Army of the United States as commissioned medical officer of volunteers or as acting assistant surgeon when the age limit is raised to 34 years. Permission to appear before the board is obtained by letter to the Secretary of War, which must be in the applicant's handwriting, giving date and place of birth and be accompanied by certificates, based on personal acquaintance, from at least two reputable persons, as to citizenship, character and habits. The examinations are thorough, the professional one both oral and written and including also clinical bedside diagnosis and prescriptions and operations on the cadaver. Candidates must also show evidence of at least one year's hospital experience or at least two years of private practice since graduation. Degrees from other than medical schools approved by the board, or first-class teachers' certificates, will usually exempt the candidate from examination in other than professional subjects, but any evidence of deficiency in general education on elementary subjects will subject the candidate to a special oral examination in arithmetic, history, geography, literature, and physics, which if not satisfactory will be cause for his rejection. Candidates claiming especial knowledge of higher mathematics, languages, drawing, chemistry, or branches of natural science will be examined in those subjects as accomplishments, and will receive due credit therefor according to their proficiency.

To save needless expense to candidates, a preliminary physical examination may be undergone by special permission, at the nearest military post or recruiting station, but any opinion from such will not be binding on the regular examining board.

The merits of the candidates in the several branches, and their relative merit as shown by the whole examination, will be reported by the board, and in accordance with such report, approved candidates will be appointed to such vacancies as may exist within two years. No allowance will be made for expenses of persons undergoing examination.

The pay of an assistant surgeon for the first five years is $1600 per annum; after promotion to captain's rank it is $2000, which, with the 10 per cent. increase for five years' service, is $2200. After ten years' service as captain the pay is $2400. The pay of a surgeon with rank of major is $2500 with 10 per cent. added for each five years of service, till after twenty years it is $3500. Liberal allowance for quarters, where not furnished, traveling expenses on duty, and other perquisites should be counted as adding to the remuneration.

Since 1893 an army medical school or special course has been authorized and maintained at the Army Medical Museum, Washington, for the purpose of instructing medical officers who have been appointed since the last preceding term of school and such others as may be authorized to attend. The course covers five months, commencing in November, and includes the subjects of the special duties of army medical officers, customs of the service, military hygiene, etc., so that the newly-appointed officers do not go at once unprepared to their new duties.

It will be noted that the chances for appointment are not limited to the vacancies now existing, but include whatever vacancies may occur within two years of a successful examination. At no time in the past have the opportunities been better for qualified young physicians to enter the regular army medical corps, than at the present time.

The army career promises to the young surgeon steady employment with constantly increasing pay and the prospects of retirement with reasonable compensation at the age when one would feel ready to be relieved of active duties. While it does not promise the rewards of exceptional success in general practice, it certainly does giver better prospects than the average practitioner can reasonably expect. The social position is good, the chance for self-improvement and scientific work is ample. The government is liberal at its posts, with instruments, means and journals, and any physician with a scientific turn of mind will find himself favorably situated to follow out his specialty. While in some respects the practice is limited and some of the posts to which a physician may be sent are not desirable, changes are always likely to take place for the better.

PROPRIETARY MEDICINES AND THE REVENUE STAMP.

A portion of the lay press is up in arms against the senate modification of the revenue bill that keeps up the stamp tax on proprietary medicines with secret formulæ. It is easy to see the motive of the opposition: the patent medicine advertiser is one of the chief sources of income of many newspapers and whatever is against his interests is against theirs also. This is no reason, however, why the interests of the public should not be held as above those of owners of private formulæ and advertising publishers. Patent medicines, so-called, are as a class directly harmful to the public, and it is unfortunate that the tax is not great enough to put them out of existence. But failing this, there is no reason why they should not contribute to the government revenues. It will, moreover, be a distinct advantage to the medical profession to know by a government mark, at sight, what preparations are ethical and what are not. The amended bill is now before a conference committee, and we trust that this senate amendment will go through unchanged.

A CENSORSHIP FOR ARTICLES OF THE MATERIA MEDICA.

The choice of drugs in the treatment of disease is daily becoming increasingly difficult, not only on account of the large number being constantly exploited, but more especially by reason of uncertainty as to their nature and efficacy. Only one who has been placed in a position requiring a clear-cut decision can realize how great, at times, is the difficulty of forming an opinion as to the medicinal value and the ethical standing of a large number of preparations on the market at the present day. We fear that often the most advertised remedies—sometimes irrespective of their merits—are those that are most largely used. For these reasons we sincerely join in the hope recently expressed editorially,[1] that the near future may see established "a proper censorship, to act as a directing agent, protecting the profession from deception," whose duty it shall be to decide as to the therapeutic value and the ethical character of all, and especially new, drugs and combinations of drugs, as well as a host of allied substances, such as glandular extracts, artificial foods, food-substitutes, and the like, offered to the medical profession. As matters stand, guilty and innocent among manufacturing pharmacists must suffer alike, to the detriment and the disadvantage of the practitioner of medicine.

FATALITY OF THE RATTLESNAKE.

A paragraph is going the rounds of the lay press that, according to the statements of a prominent professor in the University of Chicago, death from rattlesnake bite is a great rarity. He is reported as saying that for twenty years he has sought in vain for an authoritative case of death from that cause, and though many reports have been investigated they have proved unfounded. Only recently has he come upon a genuine case, and it is sufficiently remarkable to make it especially notable as an exception to the general rule of the non-fatality of rattlesnake bite. It is only fair to state, in this connection, that the professor referred to is not a medical man and is not connected with the medical department of the university. This will probably account for the ill success of his researches to discover fatal cases; if he had consulted medical literature or had a wide acquaintance with medical practitioners, the results would have been different. It is true that popular ideas of the deadliness of snake bites are exaggerated, and that the bite of some of the smaller and more common species of the Crotalidæ are not as serious as those of the larger ones. There is, however, ample reason to avoid such accidents, and if deaths are rare they *nevertheless* are frequent enough to justify the common dread of these reptiles. It would be unfortunate should such utterances be credited to the extent of leading any one to needless risks or to avoid necessary precautions as regards bite from poisonous snakes.

JAMAICA-GINGER DRINKERS' AMBLYOPIA.

Since 1897 a number of cases of amblyopia from the use of extract of Jamaica ginger have been reported in medical journals, two of which having appeared within the last month. In all cases the cause of the symptoms has been credited to the ginger constituent, and some speculation has been indulged in as to how it could produce the retrobulbar neuritis or whatever other lesion was assumed to be its underlying pathologic condition. Aside from these observations, there is no evidence of any such special toxic action of ginger. It may, if taken in excess, be irritating to the stomach or throat, but it has otherwise no record to place it among the active poisons to the nervous system. This fact has been one of the puzzles to the reporters of these cases. Alcohol in excess, especially with tobacco, can cause the symptom, but the ginger-essence drinkers do not appear to have imbibed enough alcohol to thus account for it; at least it was not so credited. Now, however, there comes a report from Baltimore that certain manufacturers or wholesale druggists have been putting out on the public an essence of ginger the alcoholic constituent of which is methyl alcohol, or possibly what is called methylated spirit, instead of the more expensive ethyl alcohol, a substance which Casey A. Wood[1] and others have shown to be quite capable of producing amblyopia, not merely when ingested internally, but also when inhaled or otherwise absorbed in its concentrated form. This, if true, and it is said that the accusation is backed by the Medico-Chirurgical Faculty of Maryland, will go far to account for the misfortunes of the ginger-essence topers who are said to exist in large numbers in the dry towns of Maryland, West Virginia and Pennsylvania. The way of the transgressor whose appetite for alcohol leads him to indulge in drug substitutes is hard in many ways, and this is only one of them. It is likely, moreover, that the transgressing druggists may also find themselves embarrassed with damage suits and a more or less dilapidated reputation.

---

[1] Merck's Archives, January.

THE HEALTH OF THE ARMY IN THE PHILIPPINES.

The annual report of Col. Charles R. Greenleaf, assistant surgeon-general U. S. A. and chief surgeon of the division of the Philippines, contains a number of interesting facts. He shows that the percentage of non-effectives in the forces has decreased, but he thinks that sickness and mortality can not be expected to decrease in the future as the effects of tropical exposure are cumulative. In cases of reduced vitality from tropical diseases, a return to the United States is an imperative necessity, and this is accentuated by the effects of nostalgia and mental strain due to the special character of the service in the small posts and the assassinating methods of the insurgents. For want of a better name, the mental state thus induced is called insanity, but it is often completely cured by the journey home. It is evidently a state of neurasthenic depression hardly deserving the name of insanity. While somewhat pessimistic in tone in some respects the report still gives encouraging facts. With improved sanitation, Dr. Greenleaf believes the sickness could be reduced by nearly one-half; the embarrassments in obtaining this are due chiefly to the shortage of medical officers—there are only 233 effective to supply over 400 posts, supervising duties, general hospitals, China details, etc., taking up the remainder of the already inadequate force of 336 surgeons in the archipelago. This is one of the worst features of the situation and is aggravated by the unavoidable inexperience of many of the acting assistant surgeons, who have to fill out the number and supplement the small number of regular army officers. Other features of interest in the report are the data as to prevalent disorders, among which we find that venereal disease, that special scourge of the British army in the tropics, has only a very subordinate place; the remarks on the army ration, on leprosy, etc. The report, while brief, is a most interesting medical document, and one that is an important contribution to military medical literature.

TREATMENT OF CHRONIC CATARRHAL DISEASE OF THE MIDDLE EAR BY MEANS OF INTRATUBAL INJECTIONS OF PILOCARPIN.

In many cases of impaired hearing dependent on catarrhal and adhesive processes in the middle ear, considerable improvement can be effected by patient, persistent and systematic treatment of the nasopharynx and the ear itself through the Eustachian tube. In some, however, the auditory defect is extremely resistant, and, together with tinnitus and other manifestations, may be a source of great annoyance and distress. Surgical measures have been proposed in the treatment of such cases, but the results can not be said to be as brilliant as the character of the therapeutic procedure would justify hope of their being. Some twenty years ago Dr. Adam Politzer, the distinguished Vienna otologist, recommended subcutaneous injections of pilocarpin hydrochlorate in the treatment of certain chronic affections of the middle and the internal ear. A number of years later he began to make the injections directly into the ear through the Eustachian tube, instead of beneath the skin, with good results. Other observers have not reported equal success, but Fischenich[1] summarizes the results of his experience in 120 cases of various forms of disease of the middle ear, attended with catarrh, sclerosis and adhesions. The cases were principally such as had proved unyielding to other methods of treatment, and the impairment of hearing was generally marked. The manipulation, which is preceded and followed by ordinary catheterization, consists in the introduction into the middle ear, through a large aural catheter, of an appropriate elastic catheter with a large central opening, followed by the injection of from 6 or 8 to 10, 12 or 16 drops of a 2 per cent. aqueous solution of pilocarpin hydrochlorate. The injection is immediately followed by vertigo and pain, which, however, soon subside. The number of injections varies between thirty and fifty, in accordance with the severity of the case. The course of treatment is to be concluded by a series of insufflations of air. The resulting improvement often continues after the treatment has been suspended.

THE INJURIOUS CONSTITUENTS OF POTABLE SPIRITS.

Inasmuch as all forms of spirit ordinarily drunk contain ethylic alcohol in common and largely, the varying effects to which they give rise qualitatively must be due to the presence of other substances. Among these are aldehyd, compound ether, fusel oil, and certain volatile basic bodies. These are present—and more particularly the aldehyd—in larger amount in raw than in matured spirit; and it is probably for this reason, among others, that ripe spirit is preferred and that its use is followed by less unpleasant secondary effects. Some experimental observations recently recorded by Brunton and Tunnicliffe,[2] go to confirm the opinion that the especially troublesome effects of intoxication with spirits is due not so much to the ethylic alcohol as, in part at least, to the aldehyd, and especially that known as furfural. This is derived from a class of substances designated pentosanes, which are present in the cellulose of the grain husks used in the preparation of various forms of spirit. It was found experimentally that furfural in active doses causes paralysis of voluntary muscles, and, later, clonic and tonic convulsions, with rapid and irregular breathing—all of a remarkably transient character. From smaller doses ataxia, tremors and twitching, especially of the facial muscles, resulted. In man pain developed at the back of the neck, extending to the occipital region, with a sense of throbbing and pulsation in the vessels of the head, and followed by dull headache for some time. On removal of the aldehyd from the spirits used recovery was much more sudden and accompanied by less marked secondary symptoms. The animals, instead of being restless and evidently uncomfortable, refusing food and exhibiting signs of bad temper, were quiet and soon restored to the normal. These observations emphasize the necessity of ensuring the purity of articles for internal consumption, whether for dietetic or for medicinal purposes, and they raise the question whether it were not preferable, as has often been urged, when alcohol is indicated in the treatment of disease, that a chemically pure article of this, rather than whisky, brandy or wine, should be used.

Medical News.

CALIFORNIA.

The Oakland Medical College's new building will be ready for the reception of students by September 1.

Dr. Paul S. Anderson, Redlands, has been appointed assistant health officer of San Bernardino County, vice Dr. Gayle G. Moseley, resigned.

The Woman's Hospital has been incorporated at Los Angeles, with a *capital stock of $20,000. It is to be devoted* entirely to the needs of *women.*

The death-rate of Los Angeles for January was the highest in the records of that city—28.22 per 1000 *per annum.* Of the 241 deaths, 93 were from diseases of the respiratory system, 178 of the 241 were from other than the Pacific coast states.

The County Hospital, just erected at Riverside at a cost of $20,000, has been found too small for its intended purpose. The county board of supervisors has purchased eight acres of land adjoining the hospital, on which it is proposed to erect two ward-cottages.

FLORIDA.

Dr. Joseph Y. Porter, Key West, state health officer, was elected a member of the legislature.

Dr. Luby S. Smith, quarantine officer at Carrabelle, has been made special agent of the State Board of Health at Arcadia.

Dr. Marcellus McCreary, Pensacola, has been appointed a member of the board of medical examiners for the First Judicial District, vice Dr. Charles B. McKinnon, resigned.

GEORGIA.

The Atlanta Board of Health has requested the city council to define its duties, especially as to the treatment and handling of smallpox cases. The council *is also asked* either to give the board a free *hand or to relieve* it of this portion of its duties.

Proprietary medicines are to be inspected by the state commissioner of agriculture, whose decision as to their usefulness and wholesomeness is to be final. The especial qualifications of the chief of agriculture, who is supposably a layman, to pass upon these matters, however, are not clear.

ILLINOIS.

Chicago.

Dr. Andrew McDiarmid has petitioned the circuit court to be allowed to resume his family name of McDermid.

Dr. John S. Marshall, one of the board of three appointed to examine applicants for the position of dentist in the army, reported for duty to the Surgeon-General, February 17.

The mortality for the week ended February 16 was 504, a death-rate per 1000 of 15.46 per annum. Violence caused 30 deaths and disease of the respiratory system 195; 105 persons died who were over the age of 60, and 98 infants under 1 *year; 298 males and 206 females died.*

The Chicago Lying-In Hospital reports that the demand for rooms is so great that an immediate enlargement of the building is imperative. Plans have been prepared and it is hoped that the work may be started in the spring. During the year just past 974 patients have been treated and 11,129 visits made.

Virtue of Vaccination.—The commissioner of health calls attention to the freedom of the police force from smallpox. No known case of the disease has occurred among members of the force in more than seven years, and this immunity, notwithstanding their frequent exposure, is due solely to the enforcement of vaccination. Similarly as to school children, among an average yearly *population of more* than 250,000 public and parochial school pupils, there have been only four known cases of smallpox in the last ten years, and these were in children admitted to school on fraudulent certificates of vaccination. As object-lessons of the virtue of vaccination these facts are sufficiently striking.

The Public Health Conditions.—These are still satisfactory. There has been no such increase of throat and lung diseases as might have been anticipated from the meteorologic conditions of the past fortnight and the contagious diseases of childhood—diphtheria, scarlet fever, measles and whooping-cough—are neither usually prevalent nor fatal. The smallpox situation remains unchanged—only 17 new cases during the week. At the close of the previous week there were 44 cases in the Isolation Hospital; 17 were admitted during the week, and 23 discharged, with no death, 38 remaining under treatment. With one exception the cases are mild and promise speedy recovery. The commissioner of health announces that the stock of glycerinated vaccin lymph on hand has ripened sufficiently to make resumption of vaccination safe.

INDIANA.

Dr. Walker Schell, Terre Haute, returned from his European trip, February 13.

Dr. Ernest Moraweck, Tell City, has returned after several years' study in Vienna, and will locate in Louisville, Ky.

A bill has been introduced in the house increasing the salary of the secretary of the State Board of Health from $1200 to $2800, and requiring him to devote his entire time to his official duties.

The Dowie heresy and its prototypes will continue to *flourish* in Indiana if the senate upholds the action of the *committee which* recommended the indefinite postponement of a bill providing *that a physician must* be called in case of sickness of children *or dependents,* and providing further a penalty in case of the death of a child or other dependent without *medical attendance.*

IOWA.

Dr. John W. Lauder, Afton, was elected state physician of the Modern Woodmen of America on February 13.

Dr. Fred W. Powers, Reinbeck, has been appointed to the position on the State Board of Health made vacant by the resignation of Dr. Joseph A. Scroggs, Keokuk.

Dr. James F. Presnell, acting assistant-surgeon in the army, formerly a practitioner in Lake View, has been nominated by the President as assistant-surgeon with the rank of captain.

KENTUCKY.

Dr. Marion G. Milan, who has been health officer of Paducah for six years, has resigned.

Dr. J. Hunter Peak, Louisville, who was recently deposed as local pension examiner, has been appointed special medical examiner of the Bureau *of Pensions* for the District of Kentucky.

Health Needs of Louisville.—Dr. Mavarell K. Allen, health officer of Louisville, states officially that the chief needs of his department are a city chemist, better facilities for protecting child-life against *infectious* and contagious diseases, proper disinfection of houses, more inspectors and more clerical aid. For these purposes $15,000 is needed for the year. The council has appropriated less than half that amount for the department.

MARYLAND.

Dr. C. Z. Wingard, Funkstown, was struck by a train, near Hagerstown, on February 13, and seriously injured.

Health Reccommendations.—City Health Officer O. W. Ragan, M.D., Hagerstown, recommends that the city council prohibit spitting on the sidewalks, in public conveyances and buildings; the keeping of hogs in the city from May 1 to October 1; the use of slaughter-houses from May 1 to October 1, and the rendering of tallow for the same period, except by improved machinery sanctioned by the sanitary board.

Baltimore.

Dr. Edwin F. Moriarty has been appointed assistant resident physician at the Baltimore University Hospital, vice Dr. Wm. F. Stover, resigned.

The total deaths for the week ended February 16 were 242, pneumonia reaching the unprecedented number of 59. There were also 31 deaths from other diseases of the respiratory system.

Dr. John M. T. Finney was elected president of the Princeton Alumni Association of Baltimore for the ensuing year. President Patton advocated a preparatory medical school at Princeton.

The health department is enforcing a rule that all children recovering from diphtheria, scarlet fever or measles show a certificate from the department before they are allowed to return to school.

The death-rate has been alarming of late, that for the week ended February 2 being greater than any in the last five years. No less than 62 deaths from pneumonia were reported. Consumption caused 36, influenza 10, and the total mortality was 262.

Rohe Memorial.—A Rohé memorial meeting was held by the Medical Society of the College of Physicians and Surgeons, on February 6. A beautiful tribute to Dr. Rohé as man and friend was read by his colleague, Prof. Wm. Simon, and personal reminiscences were given of the deceased physician and alienist by Drs. A. Friedenwald, J. Chambers, T. A. Ashby, and others.

MASSACHUSETTS.

The Board of Health of Fall River has elected Dr. Albert C. Dedrick, chairman, and Dr. Louis V. Cabana, agent.

Dr. Thomas J. Dion has been reappointed a member of the Quincy Board of Health, and Dr. Charles W. Garey has resigned.

Dr. W. J. Campbell has been elected house physician of the Worcester City Hospital, and Dr. Albert Wood, vice-president of the board of trustees.

A petition has been received in the house of representatives to the effect that any person not registered as a physician or surgeon who advertises as a healer of disease shall be punished by a fine of not less than $100 or more than $500 for each offense.

MICHIGAN.

Dr. Frank W. Martin, Portland, was elected state physician of the Modern Woodmen of America, February 14.

Dr. Albert B. Simonson, Calumet, has succeeded Dr. Emmet H. Pomeroy as chief of the medical staff of the Calumet and Hecla Company.

A Dowie Disciple in Kalamazoo, whose children have not been allowed to return to school because they had not been vaccinated, threatens to test the state health laws, and to have a bill introduced in the legislature making vaccination of school children optional with parents.

MISSOURI.

Dr. James W. Smith, Pleasant Hill, has been appointed president of the board of managers of the State Hospital for the Insane, at Fulton.

Lewis County has accepted the new law providing for county boards of health and has named Dr. W. B. Simpson, La Belle, as its medical adviser.

The Stylus has been purchased by, and will be consolidated with, the *Interstate Medical Journal*, and the two publications continued under the latter name. Dr. William Porter, editor of *The Stylus*, will be associated with Drs. W. B. Outten, R. B. H. Gradwohl and O. F. Ball, in the editorial management.

MONTANA.

Northern Pacific R. R. employees have received notification from headquarters at St. Paul to immediately report to their own or the company physician and be vaccinated unless they have been vaccinated within the last four years.

NEBRASKA.

Dr. Ruth M. Wood, Lincoln, has been appointed physician to the Girls' Industrial Home, Milford.

Dr. Hallie D. Ewing, Hastings, has been re-appointed second assistant physician at the Asylum for the Chronic Insane, at that place.

A hospital-corps school for the instruction of privates of the hospital corps of the army, in the duties of their position, is to be established at Fort Crook.

NEW YORK.

The senate has passed the bill abolishing the present State Board of Health, and establishing a single-headed commission.

The Niagara County Medical Society held a special meeting at Lockport, February 9, and adopted resolutions in memory of its lately deceased member, Dr. Henry C. Hill, of Lockport.

Professional Confidence.—A bill has been introduced into the legislature to include nurses within the scope of Sections 834 and 836 of the Code of Civil Procedure, so as to place on them the same restrictions as on physicians, regarding revealing information obtained from patients while serving in a confidential and professional capacity.

New York City.

Dr. Alfred E. Meyer, while at El Paso, Texas, on his way to California, in the capacity of medical adviser and friend of a wealthy banker and his wife, was drugged, assaulted and robbed.

A bust of Dr. Horace Green, a pioneer in the medical profession of the city, was presented to the New York Academy of Medicine, February 7, Dr. D. B. St. John Roosa making the presentation address.

The Platt Pavilion, an addition to the New York Eye and Ear Infirmary, erected to the memory of James N. Platt, through the generosity of the family of the late Justin A. Bliss, will be opened to the public in a few days. It is a fireproof edifice and contains isolated wards for the treatment of contagious ophthalmia.

New Hospital Site.—The New York Red Cross Hospital and Training School has just closed negotiations for a new site for the hospital on Central Park West, near One Hundredth street. The plot measures 99 by 100 feet, and cost $100,000. The plans contemplate the erection of a hospital with accommodations for 100 patients and a nurses' home for about twenty nurses.

Bellevue Hospital.—In the face of the recent presentment of the grand jury, and the demonstration that Bellevue Hospital is maintained at a much lower per-capita rate than other institutions of its kind, the present city administration flatly refuses to give another dollar toward carrying out the much-needed work of reform. Six new nurses, men of middle age, who have had experience in the care of the insane, have been appointed to duty in the insane pavilion, and are said to be receiving $30 each per week.

OHIO.

Dr. Edward C. Brush, Zanesville, has been appointed local surgeon of the Wheeling & Lake Erie R.R.

Dr. F. W. Smedley, who resigned as health officer of Cleves in January last, has been re-elected to that position.

The City Council of Akron has donated $5,000 to aid in ridding the city hospital of its indebtedness of $15,000. When this has been accomplished, a contingent donation of $100,000 will be made by O. C. Barber.

Cincinnati.

To Hold Murderers.—Dr. Harmon, of Longview Asylum, and Prosecutor Hoffheimer, have arranged that all patients at Longview, who are sent to the hospital after being charged with murder, will not be dismissed until the prosecutor has received proper notification.

Divine Healer Bound Over.—Squire Winkler, February 18, refused to dismiss the cases of Frank Brokamp and Mrs. "Dr." Yaeger, charged with practicing medicine without a license. He held that the alleged divine healers do not, according to the plea of their attorney, come under the provisions of the statute relating to osteopaths. He said that, at any rate, osteopaths must be registered, and the defendants had not been. He bound Brokamp over to the grand jury under a $500 bond, and continued "Dr." Yaeger's case for a week. On cross-examination Brokamp was asked by the attorney for the State Medical Board what he knew about anatomy. The healer looked puzzled and asked the judge what the word anatomy meant. His own attorney attempted to excuse his client on the ground that he was a German and did not understand certain words in the English language. He was then asked how he could diagnose a patient's illness if he could not tell the symptoms of disease. The answer was that the same treatment applied to everything from toothache to heart disease. When asked what the treatment consisted of, the defendant refused to answer, stating that that would be revealing professional secrets, and that every physician *in town could cure every ill, if he knew his (the healer's)* secrets. *On* cross examination he admitted that while not healing he acted as gardner to the *metaphysical institute.*

PENNSYLVANIA.

Dr. Morris H. Koch, Kutztown, *fractured both arms in a* runaway accident, January 30.

Dr. Harry M. Acheson was re-elected president of the board of Health of Washington, on February 7.

Changes in Hospital Staff.—The *death of Dr. Schneider* has necessitated several changes in the staff of the Williamsport Hospital. Dr. Thomas C. Rich has been elected secretary of the board of managers; Dr. William E. Glosser has been placed on the medical staff, and Dr. John A. Klump made abdominal surgeon.

Philadelphia.

The Wills Eye Hospital has added to its surgical staff Drs. John William Pancoast and William L. Zuill.

Dr. Irvin E. Bennett, of this city, now on duty with the United States forces *in Pekin, has been made a major and* surgeon of volunteers.

***The Mutual Aid* Association** of the Philadelphia County Medical Society has received a legacy of $8,110.55 from the *late Dr. Albert Fricke.*

The Philadelphia Neurological Society, at the close of its *February* 25 meeting, will tender a reception to Drs. George L. Walton and Walter E. Paul, of Boston, who present a paper on "Astereognosis," before the Society.

The Stille Medical Society, University of Pennsylvania, gave a dinner February 15, in honor of Dr. Richard C. Cabot, of Boston. The following responded to toasts: Drs. John H. Musser, George E. DeSchweinitz and J. H. Penniman.

Appropriations.—The Wills Eye Hospital *has made a* request of the legislature for the following *appropriations: For the completion* of the contagious ward, $25,000; for its *equipment, $10,000*, and for its maintenance for two years, $40,000.

The Philadelphia County Medical Society, at its meeting on February 13, adopted a resolution *opposing the antivaccination* bill now before the state legislature. The society *in this* way endorses the compulsory vaccination law now in vogue in this state.

Dr. Keen's Holiday.—Dr. William W. Keen has asked for a leave of absence from Jefferson Medical College, *for a year,* that he may take a long-needed vacation and rest. He *intends* to go to St. Paul for the meeting of THE AMERICAN MEDICAL ASSOCIATION, and then spend a *year in a leisurely trip around* the world, returning to Philadelphia *to resume his practice* and college work in September, 1902. The rumors that Dr. Keen intends to retire from practice and teaching, he authorizes us to say are without foundation.

TEXAS.

A monument to the late Dr. Francis M. Logsdon, of Beeville, *erected by the* Woodmen *of* the World, was unveiled, February 1.

Dr. John Cunningham, Ravenna, was elected February 10 to fill the unexpired term, in the house of representatives, of W. W. Riddling, deceased.

Waco physicians favor the creation of a state board of health, and have petitioned the *legislature to better the* health and quarantine laws of the state.

WASHINGTON.

Dr. William C. Gibson has been chosen president of the Seattle Board of Health for the *ensuing* year.

Dr. Walter F. Morrison, Spokane, *has been* appointed physician of Spokane county, vice Dr. Benjamin R. Freeman, term expired.

Seattle's mortality *for 1900* is said to have been at the rate of 8.69 per 1000 per annum. The *total deaths* for the year were 783.

Dr. N. Fred Essig, Spokane, has been appointed surgeon for the Kalispell and Cascade divisions of the Great Northern Railway, to succeed Dr. Donald G. Russell.

CANADA.

Dr. H. G. Barrie, Toronto, who was in South Africa as the Y. M. C. A. representative, will shortly leave for Shanghai, to do mission work for that organization.

Smallpox in Northern Ontario.—The Provincial *Board* of Health of Ontario recently held a meeting to consider the outbreak of smallpox *along* the Canadian Pacific Railway in the northern section of the province, at Sudbury and elsewhere. The disease has appeared in several places, all the way from the "Soo" to Ottawa; and Dr. C. A. Hodgetts, of Toronto, has been sent to Sudbury, where he has discovered ten cases.

Diplomas in Legal Medicine.—The *corporation* of McGill University met last week and the proposal of the medical faculty to grant diplomas in legal medicine was approved. The diploma will be awarded after a special post-graduate course under certain specified conditions, yet to be made public. The matriculation standard of the medical faculty was also discussed, *and it is proposed* to raise the standard and make it equivalent to that set by the highest requirements of any prov*ince in the Dominion.*

The Tuberculin Test.—While the medical men were holding their conference *for* the purpose of limiting the ravages of tuberculosis in Canada, the cattle men were *holding* a convention in the same city for the purpose of getting rid *of* the tuberculin test. In Canada the law requires that a strict test *by tuberculin* be made *on all* imported cattle while in quarantine. As a result of this conference with the *minister* of agriculture, it was agreed that the regulations should be somewhat modified. Toward this end legislation will be introduced during the present session of parliament, abolishing the law which now prohibits selling the hides of tuberculous stock, as scientists agree that there is not the slightest *danger* from selling these. The minister was *opposed to the abolition* of the tuberculin test, but some changes may be made regarding the employment of the test in thoroughbred cattle imported for breeding purposes.

Ontario Asylums Report.—The annual report of the asylums for the lunatics and idiots of the *province gives* the asylum population of Ontario as 5512, with an average of 5137 in daily residence. In 1900, the expenditure for the mainten*ance in the province* was $634,977.42, the per capita cost being $126.26. During the year 1900, 254 patients recovered, an increase of seven *over* the previous year, and 311 were discharged on probation, the average for the previous ten years being 255. The number of deaths was 269, a decrease of 23, as compared *with 1899.* Seventy-six per cent. of the population was employed, the *percentage* for the previous ten years being 75. The revenue from paying patients totaled $78,450.70, *nearly $4500 above the average. Dr. Daniel Clarke,* superintendent *of the Toronto Asylum,* contributed to the report a paper in *which he* combats the theory that insanity is purely a mental disease. *He contends that* it is always a bodily disease, and that mental or moral perturbations are occasions; not causes, *of brain disease.*

Health on the Yukon.—On the 15th *of January* the thermometer registered 68.5 degrees below zero: *and* the average minimum temperature for nine days was 60 *below.* Accom*panying this intense* cold in the Yukon valley was *the regular,* peculiar white mist, so dense that nothing could be seen *more than fifty* yards away. An epidemic of dog madness prevailed throughout Dawson for some days in January. As to the cause of this, Dr. McArthur, the medical health *officer,* is of the opinion that it is genuine rabies, which became prevalent by contagion. It is expected that it will take *some months* for the disease to become extinct. *All the dogs* have been impounded and so far no person has *been bitten.* Typhoid and pneumonia have been very *prevalent during* the past two months, the latter being of a very severe, acute type. "Typhopneumonia" has proved *very fatal.* It is stated that the pneumonia appears first *and* that at the time of the crisis, abdominal troubles with other marked symptoms of typhoid appear, resulting in a fatal *collapse. During the* past two months the death-rate has been very high. *Several well-known* citizens have succumbed to this fatal complication.

Conference on Tuberculosis.—*In* response to a general call by Lord Minto, the governor-general of Canada, there gathered at Ottawa, on the *14th inst.,* a large number of the prominent medical men of the Dominion as well as many private citizens. Every province of the *Dominion* was represented.

The object of the Conference was to place the Canadian Association for the Prevention of Tuberculosis, which was organized at the last meeting of the Canadian Medical Associaton, at Ottawa, on a permanent and established basis. Sir William Hingston, Professor Adami, Sir James Grant and Dr. Roddick took a prominent part in the proceedings. Professor Adami proposed that the Dominion government should have all immigrants examined for the purpose of curtailing the disease in that quarter. Dr. Chown, of Winnipeg, declared that the air of Winnipeg and Manitoba was free from the germs of tuberculosis. Dr. Lafferty, of Calgary, wants the government to erect sanitaria in the northwest, as that district is simply overrun with the tuberculous, fast becoming a menace to the residents. The associaton was organized with the Earl of Minto as honorary president and Sir James Grant as president. The association will petition the dominion parliament, now in session, to grant aid for the building of sanitaria and also to establish a department of public health.

FOREIGN.

The death of Dr. Leslie Ogilvie, physician to the Children's Hospital, Paddington Green, London, is announced.

A bounty on rats is being paid by the Stockholm authorities, as a precaution against bubonic plague.

The Congres de Gynecologie, of France, will meet this year at Nantes, September 23 to 30. Foreign gynecologists are invited to attend.

The Massage Institute connected with the Berlin University has opened a polyclinic for massage treatment of various affections, for patients of all aged.

The Leipsic dermatological clinic has been enlarged and remodelled on the latest ideals, with rooms for Finsen's light treatment, facilities for photographing, etc.

The University of Athens celebrated, December 30, the twenty-fifth anniversary of the professional career of the incumbent of the chair of surgery, Dr. S. Manghinas.

Medallion for Lannelongue.—The friends of Professor Lannelongue of Paris are to present him with a portrait medallion as a souvenir of his services as president of the International Medical Congress last August. It is to be the work of Chaplain, and every one who subscribes twenty francs will receive a bronze copy. The address of the committee having the matter in charge is: 15 rue Soufflot, Paris; Ch. Delagrave, treasurer.

Smallpox Epidemic in Glasgow.—No sooner has Glasgow freed itself from plague than it has been visited by an epidemic of smallpox. On January 25 there were 324 cases in hospital, an increase of 203 on the number a week before. Eleven deaths have occurred. The authorities are actually encouraging revaccination, and in the east end of the town the vaccination stations are often quite thronged. All "contacts" are vigorously followed up and isolated. The accommodation at the fever hospital is being largely increased in case of emergency by the erection of huts.

Plague in India.—According to the *British Medical Journal* of February 9, the number of deaths from plague in the city of Bombay, for January 9, 10, 11, 12, 13, 14 and 15 were 40, 45, 63, 45, 35, 43, and 51 respectively, or 324, as compared with 222 during the preceding week. In the corresponding week of last year, the deaths from this disease numbered 428. The plague is found in nearly every district of the city. In Calcutta 50 to 60 cases occur weekly. The government of Madras has granted 150,000 rupees toward the expense of preventing plague. During the week ending January 15, in Mysore Province, the cases of plague numbered 419, a marked increase over preceding records. The mortality in Bombay City is now sufficient to justify the present being called the fifth epidemic of the disease since 1896.

Plague Infected Ship at Bristol, England.—On January 20 a steamer arrived at Bristol, from Smyrna, Asiar Minor, with a cargo of grain. No cases of illness had occurred, but it was reported that six dead rats had been found in the grain and burned. Another was found and examined bacteriologically, with the result that bacilli were found. Still another rat was sent to Dr. Klein, who found by inoculations that the disease of which the rats had died was plague. By this time most of the cargo had been discharged. Every precaution was then taken. The ship was kept in the floating harbor and every portion thoroughly disinfected. Every one of the seventy-seven laborers employed in removing the cargo has been kept under observation and visited daily. So far no case of illness has occurred.

LONDON.

Outbreak of Plague on a Steamer at Hull.

The disappearance of the Glasgow outbreak of plague has been followed by other attempts of the disease to obtain a footing in this country, but so far unsuccessful. A steamer arrived at Hull on January 10, as previously noted in The Journal, from Alexandria, with the body of one of the crew who had died on the voyage. The body was removed to the city mortuary and buried on January 13, no suspicions being aroused. On January 12, however, two of the crew were taken ill. The medical officer of health and another doctor, who saw them on the following day, diagnosed influenza complicated by pneumonia. The patients died on January 15 and 16, respectively. Bacteriologic examination showed that they had suffered from pneumonic plague. Meanwhile two firemen had become ill, on January 14, and were removed to the hospital, and four other members of the crew were removed for isolation. Work was suspended on the vessel and it was removed to a mooring station and thoroughly disinfected. Seven more of the crew were removed to the hospital for isolation. One of the isolated men became ill and died on January 22. On January 21 the watchman of the ship, who had rendered assistance to the sick members of the crew, was taken ill and removed to the hospital. He died on January 27. The doctor who had seen the sick crew and who had assisted at the necropsies became ill on January 18 and was removed to the hospital on January 24. Bacteriologic examination of his sputum showed that he was suffering from pneumonic plague. His condition was critical for some days, but he is now recovering. In no case were enlarged glands detected; all were of the pneumonic form of plague. Altogether seven deaths have taken place, and the bodies have been cremated. The nurses and all others who have been exposed to infection have been treated with Haffkine's prophylactic serum. The names and addresses of all persons who have been in contact with or in any way associated with the vessel have been taken and their homes visited daily. Apparently all danger of the disease spreading has passed.

Intraperitoneal Rupture of Ovarian Cysts.

At the Edinburgh Obstetrical Society, Dr. Haultain recently read a paper on this subject, with special reference to operative treatment. He remarked that in the majority of cases rupture was apparently unassociated with discomfort, and therefore only in those cases in which the cyst was of sufficient size to have attracted attention could a diagnosis be made. The absence of symptoms was doubtless due to the innocuous contents of the cyst and their slow escape. In the greater proportion of the recorded cases severe and dangerous symptoms supervened. Palm, in his collected statistics of 25 cases, recorded 18 deaths: 3 from collapse, 6 from acute peritonitis, 3 from chronic peritonitis, and 6 from protracted fever. Nephen found that 65 out of 155 cases terminated fatally. In these instances the contents of the cysts must have been intensely irritating, and in many septic; in some death resulted from hemorrhage. The causes of rupture were numerous—violence, morbid processes in the cyst wall, in some cases from torsion of the pedicle, and intracystic hemorrhage. Gelatinous contents were slowly absorbed by the peritoneum, and might continue to distend the abdomen. More fluid contents—especially those of cysts of the broad ligament—are absorbed and the cyst may become permanently obliterated. In other cases the tumor redistends or secondary cysts take on active growth. The contents might be so irritative as to cause peritonitis and adhesions so widespread as to be an insuperable barrier to removal. The treatment of ruptured cysts consists in removal of the cysts as soon as possible. In a certain proportion of cases spontaneous cure occurs, but as delay might allow widespread adhesions to form, early operation is advisable. In operating, the surgeon is liable to be misled by the gush of fluid when he opens the peritoneum and to think that he has entered the cyst. An attempt would then be made to separate the cyst wall from suspected adhesions to the abdominal parietes, resulting in stripping off the parietal peritoneum. In these cases it is well to enlarge the opening and to introduce the hand into the cavity before attempting the separation of the cyst wall.

Oophorectomy for Recurrent Mammary Cancer.

At the Clinical Society, Mr. Stanley Boyd recently showed a woman, aged 31, on whom he had performed this operation. In 1898 the left breast was removed for carcinoma. In 1900 operation for recurrence was contemplated and abandoned. In August, 1900, the patient was emaciated; there were recurrence in the scar, two outlying subcutaneous nodules, considerable enlargement of the left supraclavicular and substernomastoid glands, which were rather fixed, and many large hard glands in the right axilla and a few in the neck. The left vocal cord was paralyzed and the patient had great difficulty in swallowing fluids. Double oöphorectomy was performed. Improvement took place rapidly from the day of the operation. On September 8 the nodules and glands, except one beneath the sternomastoid, had disappeared. On December 4 the voice and power of swallowing were normal and the patient had gained 21 pounds in weight.

Treatment of Rodent Ulcer by the X-Rays.

At the Hunterian Society, Dr. Sequeira showed three patients who had suffered from rodent ulcer of the face, for thirteen, eight and seven years, respectively. They were treated for ten minutes a day with the *x*-rays. The current employed was from 3 to 4 amperes, with a ten-inch spark. The lamp was placed six inches from the affected part, the normal skin being protected with lead foil. The ulcers healed entirely, and finally the raised growing edge also disappeared. Dr. Sequeira strongly recommends this treatment in all cases of rodent ulcer in which complete removal with the knife is impossible. It is too early to say anything of recurrence, but even if the treatment has to be repeated the patients are much better off than with progressive ulceration. Dr. Sequeira believes that so short an exposure as he has given, limited to the growth itself, is not likely to cause the serious sloughing which occasionally follows prolonged exposures. These results are interesting in connection with the equally successful results obtained from the *x*-ray by Drs. Knox and Pusey in lupus (THE JOURNAL, Nov. 10, 1900, p. 1211; Dec. 8, 1900, p. 1476).

Chronic Interstitial Nephritis in a Girl Aged Seven.

At the Society for the Study of Disease in Children, Dr. Guthrie related this case. A thin, stunted child with marked bronzing of the skin was admitted to the hospital January 6, on account of severe headaches, accompanied by vomiting, amaurosis and vertigo, which had occurred every day for two months. She never had scarlatina nor dropsy. The left ventricle was hypertrophied, the pulse of extremely high tension and the radial and brachial arteries were thickened. The urine amounted to from two to three pints daily and gave a specific gravity of 1006 to 1010. It contained albumin one-twelfth to one-half, and a few granular and hyaline casts. After admission the symptoms continued. She wasted rapidly and the heart enlarged. On the 17th she had two fits with loss of consciousness, rigidity and convulsions almost confined to the right side. On the 30th she had three more fits. During the eclamptic period the urine was fourteen to eighteen ounces, but in the intervals it rose to 106 ounces a day. On February 4 she became strange in manner. She gradually became comatose and died on the 7th. She was never dropsical. At the necropsy the heart was found hypertrophied and dilated. There were two large hemorrhages in the right cerebral hemisphere. The arteries generally were thickened and the kidneys showed marked interstitial nephritis.

Interstitial nephritis is very rare in children. Dr. Guthrie found records of eight similar cases between the ages of 5 and 14. The symptoms were precisely similar to those in adults.

Correspondence.

Diagnosis of Rabies.

PHILADELPHIA, Feb. 11, 1901.

To the Editor:—In THE JOURNAL for February 9, page 401, you give a report of the meeting of the Philadelphia Pathological Society for January 10, which includes a summary of the paper on "The Rapid Diagnosis of Rabies," by ourselves, and in your "Current Literature" you refer to this in place of an abstract of the paper. The report sent to you is so hopelessly muddled and inaccurate that we must beg space to correct it. Your correspondent has failed not only to give the facts as we presented them, but also to grasp the primary object of our work, which was an examination of the claims made by Van Gehuchten and Nélis as to the changes which occur in the intervertebral and plexiform ganglia in cases of rabies, and a comparison of their findings with those of Babès in the medulla oblongata, to which he has given the name "rabic tubercle." The method given by your correspondent as that followed by us is a hopeless jumble of two that were described. We did not use "Weigert's methylene blue" on any occasion, not knowing the preparation. We stained our sections according to Nissl's method, and with hematoxylin and eosin, the latter of which we found preferable for general use. We have examined the ganglia in twenty-eight cases of rabies, and in all of them found the lesions described by Van Gehuchten and Nélis, and believed by them to be the specific lesion of the disease. In twenty-one of these we examined also the medulla after the method of Babès, and in ten found the "rabic tubercle" described by him. We conclude, therefore, that while the method of Babès may give great assistance in some cases where the ganglia are not obtainable, for general use the procedure of Van Gehuchten and Nélis is preferable and more reliable, the changes described by them having a positive diagnostic value.

In the postmortem diagnosis of the case of the child detailed, cultures were made from the rabbits which succumbed to inoculation, carried through four generations, for the purpose of excluding accidental infections. The sterility of our cultures enabled us to say with absolute certainty that the animals did not die of any known bacterial disease. As the micro-organism of rabies has not yet been discovered and never cultivated, the results obtained are regarded as strong evidence that the cause of death was rabies. It was this conclusion we drew from our failure to obtain growths in our culture-tubes, not "that the micro-organism of this disease is different from that of any other type." Very sincerely,

MAZYCK P. RAVENEL, M.D.
L. J. MCCARTHY, M.D.

Result of Governor's Insults to Medical Profession.

DENVER, COLO, Jan. 31, 1901.

To the Editor:—THE JOURNAL has shown such an intelligent appreciation of the character and official acts of Charles S. Thomas, late governor of Colorado, that I feel sure you will record with some degree of satisfaction a few facts in connection with his recent failure to secure election to the United States Senate.

As long ago as last summer the medical profession of Colorado was actively awake to its duty in connection with Mr. Thomas's senatorial candidacy, and without regard to party affiliation, practically every regular physician in the state took an interest in this aspect of our political campaign. Early recognizing the probability of democratic control of the general assembly, physicians made it their business to work at primaries and in conventions for the nomination only of such democratic or "fusion" legislative candidates as would promise to oppose the ambitions of Governor Thomas. When we consider that the governor at that time was the supreme head of about as perfect a political machine as this state has ever known, the difficulties of our task may be imagined.

But the election occurred. The fusionist or democratic control of the general assembly was even by a greater majority than they themselves had anticipated. The governor felt perfectly secure of the senatorial nomination from the "fusion" caucus. There never was a time at which he claimed less than within four votes of enough to nominate. Those four votes it was an impossibility for him to secure. No arguments, no political influence, no improper proposals could induce even so small a number of the opposition to come to his support. The members who had pledged themselves to the doctors of their various districts stood by their pledges and the ambition of Governor Thomas's life ended in a tearful withdrawal of his name.

The medical profession of Colorado congratulates itself that the gratuitous and malevolent insults heaped upon it two years ago in the remarkable veto message of the governor, have been resented in the only manner that he—as a politician—could appreciate. When scheming politicians realize that physicians propose to assert their rights and privileges as citizens in an effective manner, we may be treated with more courtesy as an organized profession. Very respectfully,

WILLIAM P. MUNN,
President Colorado State Medical Society.

[The above shows what physicians can do if they work together.—ED.]

Deaths and Obituaries.

Samuel C. Busey, M.D., University of Pennsylvania, 1848, died at his home in Washington, D. C., February 12, aged 71. He was born in Maryland and began his medical studies with Dr. Hezekiah Magruder in Georgetown. After his graduation, he returned to Washington, where he engaged in active practice. He worked his way to the front at once. He served the Medical Society of the District of Columbia six times as its president, was professor of materia medica and diseases of children in Georgetown Medical School, and was one of the founders of the Children's and Garfield hospitals. He was a member of THE AMERICAN MEDICAL ASSOCIATION, took especial interest in municipal sanitation and his researches on this subject were painstaking and his findings valuable. On the fiftieth anniversary of his graduation in medicine, Dr. Busey was tendered a banquet by the local profession. Several years ago he fractured his thigh by a fall down an elevator shaft and never regained strength. During the last three years he has devoted his attention to literature and especially that relating to the history of the District of Columbia.

Fred J. Hodges, M.D., Chicago Medical College, 1888, died February 18, at the age of 36. After his graduation he practiced medicine a few years in Chicago, later in Anderson, Ind., and for the last few years had been associated with his brother-in-law, Dr. Rinehart, at Ashland, Wis. Six weeks ago, in performing an operation, Dr. Hodges was poisoned through an abrasion on his hands.

Gustavus Scott Franklin, M.D., College of Physicians and Surgeons, New York, 1862, at one time a member of the Ohio State Medical Society and of THE AMERICAN MEDICAL ASSOCIATION, died at his home in Chillicothe, Ohio. The Ross County Medical Society, of which he was one of the founders, passed resolutions of regret and sympathy at a special meeting held February 8.

Curtiss H. Osborne, M.D., Yale University, New Haven, Conn., 1877, a member of THE AMERICAN MEDICAL ASSOCIATION, died at his home in Pasadena, Cal. The Pasadena Medical Society attended the funeral in a body, and passed resolutions expressive of regret and sympathy.

Julius A. Mayes, M.D., Medical College of the State of South Carolina, Charleston, 1844, an expert botanist, and at one time president of the State Medical Association, died at his home in Mayesville, S.C., February 9, after a short illness, aged 78.

Edwin S. Miller, M.D., University of Pennsylvania, Philadelphia, 1878, a prominent physician of Altoona, Pa., and a member of THE AMERICAN MEDICAL ASSOCIATION, died from paralysis, at his home in Altoona, February 10, aged 45.

Augusta A. Steadman, M.D., Woman's Medical College, New York, 1881, formerly a practitioner in Taunton, Mass., but for the last ten years a resident of Amsterdam, N. Y., died at her home in that city, February 1, from pneumonia, aged 50.

Aaron T. Shallenberger, M.D., Jefferson Medical College, Philadelphia, 1846, who had practiced in the Beaver Valley for more than fifty years, died February 6, at his home in Rochester, Pa., after an illness for five weeks, aged 75.

Julian N. Parker, M.D., Yale University, New Haven, Conn., 1867, who had practiced for more than thirty years in South Manchester, Conn., died at his home in that place after a protracted illness, February 7, aged 58.

Charles H. Poucher, M.D., Medical College of Indiana, Indianapolis, 1893, formerly superintendent of the Indianapolis *City Hospital, died from the effects of prussic acid poisoning,* at Swanton, Neb., February 11, aged 32.

Peter Moir Barclay, M.D., New York University, 1854, a native of Aberdeen, Scotland, and for nearly half a century a practitioner of medicine in Newburg, N. Y., died February 10, at his home in that city, aged 66.

E. C. Frierson, M.D., College of Physicians and Surgeons, Baltimore, M.D., 1880, accidentally shot himself while cleaning a gun, at his home in Anderson, S. C., February 8; he died almost instantly, aged 40.

Samuel Brown Morrison, M.D., University of Virginia, Charlottesville, 1855, a surgeon in the Confederate service, died at his home, Rockbridge Baths, Va., February 4, from paralysis, aged 72.

Edward F. Davis, M.D., Miami Medical College, Cincinnati, 1872, who practiced for many years at Cleves, Ohio, died after a long period of invalidism at Hamilton, Ohio, February 11, aged 59.

Dana C. Highriter, M.D., College of Physicians and Surgeons, Baltimore, Md., 1887, died from rheumatic fever, after a short illness, at his home in Fulton, N. Y., February 9, aged 35.

Fletcher McFarland, M.D., Rush Medical College, Chicago, 1870, died recently at Jacksonville, Ill., aged 52. He was assistant physician at Oak Lawn until 1882, when he became blind.

William W. Alderson, M.D., College of Physicians and Surgeons, Baltimore, 1894, died from consumption at the home of his parents near Alderson, W. Va., January 24, aged 27.

Daniel Scott Boyle, M.D., University of Maryland, Baltimore, 1860, a surgeon in the Confederate Service during the Civil War, died at Westminster, Md., February 4, aged 67.

Leonard Kelly, Jr., M.D., Medical College of the State of South Carolina, Charleston, 1898, died after a prolonged illness at his home in Olyphant, Pa., February 10, aged 25.

Flavel H. Van Eaton, M.D., Missouri Medical College, St. Louis, 1858, died at his home in Olympia, Wash., February 2, after an illness of two years, from rheumatism.

Lucy M. Gardner, M.D., College of Physicians and Surgeons, Keokuk, Iowa, 1896, of Quincy, Ill., died from peritonitis, in La Porte, Texas, February 6, aged 42.

Michael G. Cunningham, M.D., College of Physicians and Surgeons, New York, 1883, died at his home in Binghamton, N. Y., February 11, from la grippe, aged 44.

Charles S. Jenne, M.D., University of Vermont, Burlington, 1887, died at his home in Westford, Vt., February 9, after a week's illness, from pneumonia, aged 35.

James T. Perkins, M.D., University of Maryland, Baltimore, 1877, died at his home in Springfield, Md., after a prolonged illness, February 6, aged 47.

Henry S. Mellinger, M.D., Jefferson Medical College, Philadelphia, 1845, died at his home in Cresswell, Pa., from apoplexy, February 8, aged 79.

Nathaniel B. Boileau, M.D., University of Pennsylvania, 1858, coroner of Hunterdon County, died suddenly at his home in Jutland, N. J., February 11.

William E. Boswell, M.D., Memphis (Tenn.) Medical College, 1873, died from consumption, at his home in Union City, Tenn., February 7.

William H. Edsall, M.D., Albany Medical College, Albany, N. Y., 1877, of Highland Falls, N. Y., died of pneumonia, February 9, aged 49.

Benjamin W. Tingley, M.D., Dartmouth Medical College, Hanover, N. H., died at his home in Bellingham, Mass., February 4, aged 80.

Andrew P. Glanden, M.D., Jefferson Medical College, Philadelphia, 1865, of Newport, N. J., died from paralysis, February 9.

John T. Bingham, M.D., University of Nashville, Tenn., *1860, died suddenly, at his home near Isam, Tenn., February 8.*

John Sistrunk, M.D., New York University, 1858, died at his home near Society Hill, Ala., February 5.

John H. Leary, M.D., Bellevue Medical College, New York, died in Providence, R.I., February 10.

C. L. Brock, M.D., died January 24, at his home in Sheldon, Iowa, aged 83 years.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulæ and outlines of treatment will be answered in these columns.]

Normal Salt Solution in Pleurisy with Effusion.

Dr. John A. Robison states that normal salt solution injected into the pleural cavity after removal of the fluid or when the fluid is loaded with fibrin enhances the tendency to absorption. The points he emphasizes are: 1, it increases osmosis of the fluid into the blood-vessels; 2, it increases the activity of the absorbent lymphatics; 3, it acts as a solvent and an antiseptic; 4, the heat of the injection has a stimulating influence on the pleural vasomotor nerves, dilating the capillaries and hastening the blood current.

Treatment of Severe Cases of Lumbago.

Dr. R. S. Bernice, in *Med. Record*, gives the following treatment of lumbago:

℞.	Ammonii chloridi	gr. xx	1	33
	Ammonii carbonatis	gr. v		30

M. Sig.: At one dose, well diluted in water.

Or,

℞.	Ammonii chloridi	ʒiii	12	
	Liq. hydrarg. perchloridi	℥ss	16	
	Spts. chloroformi	℥ss	16	
	Infusi gentianæ comp. q. s. ad	℥vi	192	

M. Sig.: One tablespoonful in water three times a day.

The dose of ammonium chlorid in either of these prescriptions approaches the maximum dose.

Formaldehyde in Diphtheria.

The following combination containing formaldehyde has been highly recommended in the form of a spray as a disinfectant to the throat in diphtheria:

℞.	Sol. formaldehyde (0.25 per cent.)	℥i	32	
	Potassii chloratis	ʒii	8	
	Acidi borici	ʒi	4	
	Glycerini	℥ss	16	
	Aquæ q. s. ad	℥iv	128	

M. Sig.: Use as a spray to the membrane deposits in the throat.

Taylor, in *Brit. Med. Jour.*, gives the following directions for treatment of diphtheria: A full dose of mild chlorid of mercury; swab the throat with the tincture of iodin; inhale the vapors of the tincture of iodin for five minutes at a time, using the following combination:

Tinct. iodi	ʒi	4	
Aq. destil, q. s. ad	℥iv	128	

M. Sig.: Use as an inhalation by heating over an alcohol lamp and repeat in half an hour if necessary. He recommended also, the administration of quinin, tincture of alcohol when necessary, beef tea and milk.

Treatment of Acute Catarrhal Rhinitis.

Dr. G. C. Stout, in *Ther. Gazette*, states that the treatment should be divided into prophylactic, abortive and curative. Prophylaxis embraces rational clothing, avoidance of draughts, care of the digestive functions and maintaining muscular tone. As a preventive measure a brisk dry massage of the body and limbs morning and evening is excellent. A laxative of mild chlorid of mercury and sodium bicarbonate, followed by strychnin sulphate in one-thirtieth grain doses three times a day, hot drinks at bed-time after a hot foot-bath; then covering up well in bed so as to produce general diaphoresis.

Treatment of a well-pronounced attack consists in giving a saline cathartic, and for the free discharge from the nose:

℞.	Morphinæ sulphatis	gr. 1/32		0020
	Strychninæ sulphatis	gr. 1/95		0007
	Atropinæ sulphatis	gr. 1/150		0004
	Acidi arsenosi	gr. 1/100		0006
	Aconitinæ	gr. 1/1000		00006

M. Sig.: One such tablet two or three times a day according to symptoms. And locally:

℞.	Cocainæ hydrochloratis	gr. x		66
	Acidi borici	gr. iv		25
	Aquæ destil. q. s. ad	℥ii	64	

M. Sig.: *Spray into the nose when the secretion from the nose is excessive and the breathing space narrowed.* After five minutes it is to be followed by a spray of:

℞.	Atropin	gr. x		66
	Aquæ destil. q. s. ad	℥i	32	

M. Sig.: Use as a spray once a day to the nares and allow to remain for five minutes and then gently blow *the nose.*

This should in turn be followed by an oily spray as a protective:

℞.	Menthol	gr. v		32
	Liq. petrolati	℥i	32	

M. Sig.: Spray into the nares once a day.

Pharyngitis or laryngitis, if present will be relieved by the following:

℞.	Olei eucalypti	m. ii		12
	Zinci sulphatis	gr. x		66
	Antipyrini	gr. xl	2	66
	Aquæ destil	℥ii	64	

M. Sig.: Spray into the pharynx and inhale every two or three hours.

Give internally the following tablet:

℞.	Pulv. opii	*gr. ¼ to ½*		015-03
	Camphoræ	gr. i		06
	Ammonii carbonatis	gr. i-iii		06-18

M. Sig.: One such capsule every three hours.

[The following powder may be used to great advantage instead of the spray containing cocain, but should always be prescribed and given out by the physician himself on account of the danger of contracting the cocain habit:

℞.	Cocainæ hydrochloratis	gr. v		32
	Sodii bicarbonatis	gr. iv		25
	Sodii boratis	gr. iv		25
	Iodol	ʒi	4	
	Sacchari lactis q. s. ad	ʒiii	12	

M. Sig.: A small amount to be used as an insufflation into the nares once or twice daily if necessary to relieve the congestion of the swollen turbinated bodies.

The following is very often recommended for cold in the head, although rather *heterogeneous in character:*

℞.	Quininæ hydrobromatis	gr. xx	1	33
	Podophyllin	gr. ii		12
	Aloinæ	gr. ii		12
	Atropinæ sulphatis	gr. 1/25		0025
	Strychninæ sulphatis	gr. 1/6		01
	Sodii bicarbonatis	gr. lxxx	5	33

M. Ft. *cap. No. xx. Sig.: One capsule every two hours.* —ED.]

Treatment of Bronchitis Accompanying Influenza.

Atkinson, in "Amer. Text-book of Ther.," recommends the following if the catarrhal condition is such as to produce paroxysms of coughing:

℞.	Morphinæ sulphatis	gr. ss		03
	Syrupi scillæ	ʒii	8	
	Syrupi lactucarii	℥ss	16	
	Aquæ	ʒvi	24	

M. Sig.: One teaspoonful every three or four hours.

If nausea be present and the cough troublesome, but the bronchitis not severe, the following is advised:

℞.	Morphinæ sulphatis	gr. ss		03
	Acidi hydrocyanici dil.	m. viii		50
	Spts. chloroformi	ʒiss	6	
	Aq. menthæ viridis q. s. ad	℥iss	48	

M. Sig.: One teaspoonful every three or four hours.

If the bronchitis is pronounced, he recommends more stimulating agents and prescribes the following:

℞.	Ammonii chloridi	ʒi	4	
	Mist. glycyrrhizæ comp.	℥vi	192	

M. Sig.: One tablespoonful every three or four hours in water.

Protargol in Acute Gonorrhea.

Belfield, in *Progressive Medicine*, recommends the following in the acute stage:

℞.	Hydrastis muriatis	gr. xv	1	
	Protargol	gr. xv	1	
	Glycerini	ʒiss	6	
	Aquæ destil. q. s. ad	℥iii	96	

M. Sig.: Use as an injection four times a day.

Acute Gout.

He also recommends lithium hippurate in treatment of acute gout, prescribed in the following manner:

℞.	Lithii hippuratis	ʒi	4	
	Syrupi aurantii	℥i	32	
	Aquæ q. s. ad	℥vi	192	

M. Sig.: One tablespoonful in water at bed-time; and as a local analgesic in acute gout he quotes the formula of Sir Dyce Duckworth as a local analgesic:

℞.	Atrophinæ	gr. ii		12
	Morphinæ hydrochloratis	gr. xv	1	
	Acidi oleici	℥i	32	

M. Ft. linimentum. Sig.: To be painted over the painful joint with a large camel's hair brush, and carded cotton to be superimposed, with a towel bandage.

Injections of Iodin Compounds in Syphilis.

Lang, of Vienna, in *Internat. Med. Mag.*, states that in those cases where syphilitics can not tolerate the iodids by the stomach he administers them per rectum, or when conditions are unfavorable for administration in this way, he resorts to subcutaneous injections as follows:

℞.	Potassii iodidi	℥i	32	
	Codeinæ hydrochlor	gr. vii		42
	Aquæ destil	℥i	32	

M. Sig.: Inject from fifteen to forty-five drops daily. The codein renders the injection less painful and does not retard the rapidity of absorption. In other cases he used the following:

℞.	Iodoformi	ʒi	4
	Vaselini (liquid)	ʒiss	6

M. Sig.: Inject seven drops subcutaneously every day, or every other day.

Treatment of Lupus.

Unna, in *Brit. Med. Jour.*, recommends the following paste in treatment of lupus:

℞.	Acidi salicylici		
	Solutionis antimonii chloridi āā	ʒi	4
	Creosoti		
	Ext. cannabis indicæ āā	ʒii	8
	Lanolini	ʒiv	16

M. Sig.: Apply locally to the afflicted part.

The solution of antimony is an unofficial preparation and is a powerful caustic and a destroyer of bacilli. The creosote and cannabis indicæ will relieve the pain. The salicylic acid aids penetration.

Treatment of Sciatica.

Hogge, as noted in the *Internat. Med. Mag.*, states that he has good success in the treatment of sciatica with the following injection in a limited number of cases:

℞.	Salophen	ʒii	8
	Sodii bicarb	ʒi	4
	Aq. destil. q. s. ad	℥ii	64

M. Sig. Inject two drams into the gluteal region every other day.

He states that he kept the patients in bed until the fifteenth injection was given and that all symptoms were relieved after the thirtieth injection.

Treatment of Typhoid Fever.

Dr. William Ewart, in *The Lancet*, recommends very highly the following:

℞.	Sol. hydrarg. chloridi corros. (B.P.)	m. xx	1	33
	Tinct. ferri chloridi	m. xv	1	
	Syrupi aurantii	ʒi	4	
	Aquæ destil	℥i	32	

M. Sig.: At one dose, to be repeated every six hours for ten days.

He claims with this combination to produce a rapid amelioration of the signs and symptoms, such as cleansing of the tongue, clearing of complexion and a return of the appetite, as well as the checking of the diarrhea when present. He claims that the iron acts splendidly as a local application to the ulcers and as a hemostatic, while the mercury exerts its influence upon the hepatic and lymphatic systems, as well as a disinfectant to the alimentary tract.

According to the Brit. Pharmacopeia, the mercuric solution in the above prescription contains 1/16 gr. of corrosive sublimate to each dram. Therefore each twenty minims contains 1/48 of a grain of the mercuric chlorid.

Medicolegal.

Consciousness Presumed.—The Court of Errors and Appeals of New Jersey holds, in the case of State vs. Hill, that the law always presumes a man to be conscious and sane, and if the contrary exists, thereby defeating the natural presumption, it must be shown by the party who alleges it.

Antiseptic Cotton a Medicinal Preparation.—The Board of United States General Appraisers at New York holds that merchandise consisting of a foundation of cotton batting with one surface thereof treated with an antiseptic preparation, the chief component material being cotton, is a medicinal preparation, dutiable as such under the tariff act, and not as a manufacture of cotton.

Right of Recovery for Operation.—It appeared at a trial term of the Supreme Court of New York, Kings County, in the case of MacEvitt vs. Maass, that the plaintiff, a physician and surgeon, was called in by the defendant to treat his wife. He made an examination of her, and informed the defendant that a surgical operation was necessary. They entered into an agreement that the plaintiff should perform it for $75. The trouble was an internal one somewhere in the abdomen. The plaintiff testified that a day or two later he made another examination of the patient and found conditions which were entirely new to him, and foreign to the surgical operation which he had proposed; that the first diagnosis was entirely wrong; that her condition was of much greater gravity than had been supposed from the first diagnosis; that the operation first mentioned was entirely unnecessary; that an entirely different surgical operation, but in the same region, was necessary; that it was one which would jeopardize the patient's life, whereas the first one mentioned would not have done so; and that he substantially informed the defendant of all this. But he did not say that the new operation was worth more or less than the one first proposed, or that he would charge for it more or less than the sum which had been agreed on. In fine, nothing was said by either on the subject of compensation for the new operation. The defendant simply assented to the plaintiff performing it. It was then left to the jury to find what the facts were, and to say whether the agreement for a compensation of $75 was superseded, and they gave the plaintiff a verdict for $225. This meets the approval of the court, which holds that the legal conclusion was that the defendant in assenting to the performance by the plaintiff of the new operation must necessarily have understood that the agreement previously made could not be carried out and was at an end, and that he was to pay for the new services what they should be reasonably worth. If it had turned out on the second examination that the operation first mentioned was not necessary, and that a different and only trifling operation was necessary, and the plaintiff had informed the defendant thereof, the plaintiff could not afterwards have claimed that $75 was agreed upon for that operation, although it was worth only one-third of that amount. The law would be that both parties necessarily understood that the first agreement was no longer in effect, though that was not in so many words said. Moreover, the testimony of the plaintiff and of the surgeons who assisted him in the operation, concerning the ailment of the patient and the particulars of the operation, having been excluded, as privileged, the court holds that their testimony as experts in respect to the value of the plaintiff's services could not be objected to on the ground that, as the nature and particulars of the surgical operation had not been given in evidence, there was no basis for such testimony. There was in evidence that a capital surgical operation was performed, of the time it took, and of the number of visits the plaintiff made to the patient before and after it, and the statute having excluded the particulars as to what the operation really was, the court holds that such evidence of value by the surgeons who saw them, being the best evidence which the nature of the case admitted of, must be held admissible.

May Erect an Individual Home for a Lunatic.—The Court of Appeals of Kentucky gives it sanction, in the case of Cantrill vs. Cecil, to the erection, under certain circumstances, of an individual home for an adjudged lunatic. Here was one who had an estate of $93.000 held in trust for her life by a brother, the principal to be encroached upon in case of imperious necessity only. After having been confined in public and private institutions for the insane, she was removed to the residence of a sister, who, having been advised that it was essential to do so, had erected, with the consent of the committee, but without waiting for that of the chancellor, an addition to her dwelling, at an expense of $6000, so that she could give her a sister's care, and the other could have her own "home," although she had to be confined to her rooms. The sister claimed that this addition added nothing to the value of property, and sought reimbursement therefor. The court holds that she was entitled to maintain a suit for same, but was not entitled to encroach on the principal of the estate, nor, perhaps, on the profits accumulated prior to the expenditure in question. It says that if this arrangement ought to continue as the best possible one under all the circumstances, then the ample income of the estate ought to be made available to pay for the structure which alone made it possible to continue it. Nor does it consider that the expenditure in dispute was an investment in real estate, and therefore in contravention of the terms of the deed of trust. If, in erecting the house for the invalid, there was any permanent improvement of the sister's property, the chancellor might, as matter of common justice and right, it says, charge the sister therewith, and might even provide for the contingency of the patient's immediate or early death, or the event of her ceasing to occupy the house, or of her permanent recovery of mind and health, if it should be supposed the happening of these contingencies might pecuniarily benefit the sister. But, after all, the court asks, why should the unfortunate woman be committed to private or public mad houses because there might result, perchance, some gain to her benefactor or custodian? The supreme consideration was her health, comfort and security.

Use of Boric Acid as Milk Preservative.—Section 4989 and 4990 of the Iowa Code provide that if any person shall sell any adulterated milk he shall be fined, and that the addition of water or any other substance or thing to milk is an adulteration. Construed literally, the trial judge in the case of State vs. Schlenker held that this enactment was unconstitutional; that the evident intent of the legislature was to prohibit sales of anything that would operate as a fraud upon the buyer or prove deleterious to his health, and that, as the defendant was guilty of no fraud and the adulteration was harmless, he had not violated the law, he having put about one-half ounce of boric acid in ten gallons of milk as a preservative, and told a number of customers what he was doing. But with these conclusions the Supreme Court of Iowa does not agree. It holds the statute constitutional and the definition of the term "adulteration" valid and binding. While it may be true, as a general proposition, that the legislature has no power to forbid the sale, without deceit or fraud, of a harmless and wholesome article of food, the supreme court declares that it is also true that in virtue of the police power it may pass such laws as are, or may reasonably appear to be, necessary for the health, comfort, and safety of the people. Almost every police regulation affects, to a greater or less extent, some property right; but these rights are subject to such reasonable limitations in their enjoyment as will prevent them from being injurious, and to such reasonable regulations as the legislature, under the constitution, may deem necessary and expedient. Courts will not interfere, as a rule, unless there is a plain excess or usurpation of power, and in case of doubt it should be solved in favor of the power of the legislature to make the enactment. It may be conceded that the milk sold by the defendant was not harmful to the health of those who used it; but it is certainly dangerous to the public to permit milkmen and those dealing in milk to adulterate it in such manner as to change its constituent properties. So it holds that it was not enough as a defense to show that the defendant did not intend to defraud, or that the milk he sold was wholesome. If that were enough, almost any law intended to protect the public health and safety might be overthrown. It is enough that adulteration such as prescribed by the statute may defraud or prove deleterious to the public health or comfort. The legislature may well determine that the adulteration of milk tends to facilitate vicious practices, and that it ought to be prohibited. Criminal intent not being an essential element of the offense described in the statute, it need not be shown in order to justify a conviction.

Miscellany.

Carcinoma in Sweden.—The official statistics tabulated by Dr. U. Quensel, of Stockholm, show that the mortality from carcinoma has risen from 8 to 9.75 per 10,000 inhabitants during the four-year periods from 1875 to 1879 and 1895 to 1899 respectively. During the first period the women affected outnumbered the men by 192 to 100, and during the second, by 150 to 100. During the first, the carcinoma mortality represented 3.57 per cent. of the total number of deaths, and during the last, 6.27 per cent. The *Semaine Méd.*, in the abstract of his report, calls attention to the fact that the mortality is inversely proportional to the density of the population, being 10.05 per 10,000 in communities of less than 2000 inhabitants: 9.08 in towns of 2000 to 10,000, and only 8.53 in towns of more than 10,000.

Heat in Diagnosing the Presence of Pus.—According to the *British Medical Journal* of January 26, Dr. J. Lewin, of Berlin, has been making experiments which tend to show that the application of heat, while relieving pain resulting from simple acute inflammation, has a decidedly contrary effect when suppuration is present. He is said to have ascertained from the treatment of 10 persons affected with appendicitis, that where hot compresses were applied from one to two hours, 8 were greatly relieved, while the others experienced increased pain. Spontaneous cure resulted in the course of two or three weeks in the 8, but in the other 2, after trying medical treatment without result, operative interference was considered necessary and pus found in both instances. In applying the test it is important to use no other calmative means, and to keep the patient ignorant of the expected results, in order that the effect may not be modified by a dread of operation.

Lay Massage.—The physicians in Belgium are trying to have a clause inserted in the medical practice bill now under discussion, to the effect that massage and medical gymnastics belong exclusively to the domain of medicine and should not be practised by empirical masseurs, with the exception of certain mild affections of the members and the muscles of the back. Masseurs for this purpose should pass an examination before a competent body, and be entitled to a diploma. The *Progrès Méd.* of Paris expresses disapproval of this latter suggestion and urges that massage should be exclusively restricted to physicians. It gives a long list of injuries produced by empirical massage, including the aggravation of contractions, progressive atrophy, laceration of tendons, transformation of a simple arthritis into a hydrarthrosis, etc. The Belgian committee also cites cases of rupture of the tendo Achillis, followed by permanent limping, a thrombosed vein kneaded by a masseur with the death of the subject during the séance, and a suppurative appendicitis perforating into the peritoneum during massage. Zabloudowsky has also published instances of the formation of furuncles and abscesses from lay massage, proving fatal in two cases, displacement of fragments of bones in fractures, transformation of convalescing lesions into subacute, acute and chronic stages, especially in joint affections, production of ankylosis and movable kidney, traumatic inflammation of the sheaths of the muscles and nerves, enlargement of hernia and of the umbilicus, and aggravation of mild forms of hysteria and neurasthenia by the prolonged excitation of the peripheral nerves. One of our Vienna exchanges recently published a case in which a person had undergone a physical examination for some purpose, the kidneys found normal in every respect. A few days later, after some lay massage, the kidney was found transformed into a floating organ. Berlin has now a chair of massage, and special courses in massage at clinics in Heidelberg, Leipsic, Stockholm, Vienna, and elsewhere have long been open to physicians.

Societies.

COMING MEETINGS.

Tri-State Medical Association of the Carolinas and Virginia. Richmond, Va., Feb. 26, 1901.

Medical Society of the Missouri Valley, Omaha, Neb., March 21, 1901.

Portsmouth (N. H.) Medical Society.—This Society, at its annual meeting, February 5, elected Dr. Arthur J. Lance, president; Dr. Benjamin Cheever, secretary, and Dr. Andrew B. Sherburne, treasurer.

International Alcohol Congress.—The eighth international congress against the abuse of alcohol is to assemble at Vienna, April 9. The secretary is Prof. Max Gruber, Schwarzpanier str. 17, Vienna.

Alton (Ill.) Medical Association.—This Society, on February 4, elected Dr. Edward C. Lemen, Upper Alton, president; Dr. Titus P. Yerkes, Upper Alton, vice-president; Dr. Lincoln M. Bowman, Alton, secretary, and Dr. Julius H. Fiegenbaum, Alton, treasurer.

Nineteenth German Congress of Internal Medicine.—Senator will be the president at the congress of internal medicine which will be held at Berlin, April 16 to 19. The chief subjects to be discussed are: "Heart and Vasomotor Remedies," and "Inflammation of the Spinal Cord."

Vigo County (Ind.) Medical Society.—At the annual meeting of this Society, in Terre Haute, Dr. George Schell, Terre Haute, was elected president; Dr. Dupuy, Riley, vice-president; Dr. Malachi R. Combs, Terre Haute, secretary, and Dr. Cassius M. Smick, Terre Haute, treasurer.

Sault Ste. Marie (Mich.) Medical Society.—This Society, with which it is expected that the physicians of the Canadian Soo will affiliate, has been organized with the following officers: Dr. Emil H. Webster, president; Dr. Frederick Townsend, vice-president, and Dr. H. E. McLennan, secretary and treasurer.

Union County (Ill.) Medical Association.—Twenty physicians of Union County met at Anna, January 31, and organized this Society, with Dr. James I. Hale, Anna, as temporary chairman, and Dr. T. Lee Agnew, Anna, temporary secretary. Permanent organization will be effected February 27.

Atlantic County (N. J.) Medical Society.—This Society, at its annual meeting, February 6, elected officers as follows: Dr. Theophilus H. Boysen, Egg Harbor, president; Dr. William Edgar Darnall, Atlantic City, vice-president; Dr. Theodore Senseman, Atlantic City, secretary and treasurer, and Dr. A. Burton Shiner, Atlantic City, reporter.

Denver and Arapahoe Medical Society.—The board of directors of this Society has decided to "vary the monotony" of the meetings by alternating sessions at which papers are read and clinical symposia with presentation of cases and specimens, or more or less social sessions. This plan was adopted three years ago by the Chicago Medical Society, and the results have fully justified the change.

Northeastern Ohio Union Medical Association.—At the one hundred and eighteenth quarterly meeting of this organization, held in Akron, February 12, the following officers were elected: Dr. George L. Starr, Hudson, president; Drs. George S. Peck, Youngstown, and Abner E. Foltz, Akron, vice-presidents; Dr. John H. Seiler, Akron, recording secretary; Dr. Charles W. Milliken, Akron, corresponding secretary, and Dr. Harold H. Jacobs, Akron, treasurer.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Meeting Held January 23.

Dr. George Erety Shoemaker in the chair.

Malignant Endocarditis.

Dr. Albert E. Roussel reported three cases of malignant endocarditis, one following measles, one typhoid fever, and another resembling splenic-lymphatic leukemia terminating in recovery. The first case reported was that of a patient aged 22 years, who had, during youth, suffered from bronchitis. On October 25, symptoms of measles set in, followed later by fevers, sweats and chills. There were vague body pains and loss of flesh and strength. At one time the disease was supposed to be typhoid fever. The temperature was 103, the pulse small, respirations 36. The apex-beat was in the fifth interspace, where a low-pitched murmur was heard. Later the action of the heart became irregular, and a diagnosis of probable endocarditis was made. Death followed. The postmortem showed that there was no hypertrophy; the left auricle was dilated, but with greyish-white vegetations on the valves. The other valves were healthy.

The second case was a patient aged 9 years, who had measles and chicken-pox. He had been examined subsequently by the speaker, but there had been no heart lesions produced by these attacks. Sometime later he passed through a typical attack of typhoid fever, all of the symptoms and clinical signs having been present. On December 1 he had a decided rigor and abdominal pain, and pain referred to the region of the appendix. He suffered from irregular fever for thirty-three days, but at times the temperature became subnormal. The red cells numbered 3,700,000; whites 44,000, and the hemoglobin was 25 per cent. The patient presented a waxy appearance, and the abdomen would pit on pressure. The blood was examined later and showed 3,100,000 reds; 49,000 leucocytes; hemoglobin 25 per cent. The polymorphonuclears were 79 per cent.; mononuclears, 2 per cent.; transitional forms 2 per cent., and eosinophiles 1 per cent. Death followed. The heart was normal in size; the coronary arteries were very firm: the spleen showed infarcts, as did the liver.

The third was a patient who had passed a life insurance examination. The onset was marked by symptoms of rheumatism, with fever and sweats. Slight jaundice subsequently occurred. On May 22, the liver was found enlarged, the apex-beat diffuse. There was a distinct cardiac murmur which was transmitted to the left. The pulse was 116. The red cells numbered 3,000,000; leucocytes, 26,000; and hemoglobin, 35 per cent. The pulse was 148 and irregular.

The speaker stated that in malignant endocarditis streptococci are generally found on the heart valves, though the following have also been found; the bacillus lanceolatus, staphylococcus, pneumococcus, and gonococcus. Some writers believe that the condition is a primary one, while others contend that it is secondary, or is grafted on a previous heart lesion. As a rule the right heart is affected.

Dr. James Tyson stated that he had seen numerous cases of malignant endocarditis accompanied by fever, sweats and chills. He believed that the process was a septic one, and frequently never recognized during life. Pneumonia is probably the most common cause. The right heart is most frequently involved, due to the fact that the valves here receive the blood from the veins. He thought that in the next case he has antistreptococcic serum will be given.

Dr. J. M. Anders expressed his belief that the principal point of interest in regard to these cases, hinges on the diagnosis. The infection is usually a secondary one, though it may occasionally be primary. As to the diagnosis, when we meet cases in which there is a cardiac murmur, colliquative sweats, and a high grade of anemia, we should suspect endocarditis. In former days endocarditis was mistaken for typhoid fever, but the absence of leucocytosis and the Widal reaction would be against typhoid.

Epiplopexy in Liver Cirrhosis.

Dr. J. B. Roberts read a paper on "Epiplopexy in Cirrhosis of the Liver." He has recently done this operation twice, once on a man aged 49 years, whose father had died of cirrhosis of the liver. The patient had manifested symptoms of this disease and an incision was made in the usual manner, the omentum drawn out, the peritoneal surface of the abdominal wall rubber with gauze and the omentum stitched with chromicized catgut. Relief of the ascites followed.

The second patient was a man 64 years of age, whose abdomen had for the past eight months grown considerably larger in size. He had been tapped eight times. There was much jaundice, and some edema of both legs. Tube casts were found in the urine. The operation was done under cocain anesthesia. A small incision was made above the umbilicus, but the omentum could not be found and another incision was made below it. The omentum was then drawn up and spread out, then rolled over slightly so that the stitches would *not pull out*—*which* happened in one case—and then stitched to the abdominal wall.

He believes that the operation should be done as early as possible after the onset of cirrhosis.

Dr. James Tyson had seen this operation prove of great benefit to a case of cirrhosis of the liver. It had cured the ascites.

Dr. Wm. L. Coplin thought that it might be a question whether anything is gained by this operation, since it short-circuits the blood supply of the liver, and if this is done the nutrition of the body might become impaired from loss of these elements.

Dr. Ernest Laplace believes that in cirrhosis of the liver the condition can not be compared to that of a healthy organ. In the former case the liver is incapacitated anyway, and it does its work in a circuitous route. He approves of the operation as done by Dr. Roberts.

CINCINNATI ACADEMY OF MEDICINE.

Regular Meeting, held January 28.

Perichondritis Auriculi.

The president, Dr. C. L. Bonifield, in the chair.

Dr. C. R. Holmes presented a patient with this trouble, involving the right ear. He first mentioned that this affection was an extremely rare one, in fact it was the first true instance of the disease that had thus far come to his notice. The patient was a girl, about 17 years of age, on whom he had operated nine weeks previously—a radical mastoid operation. She had recovered nicely from this operation, and just as he was on the point of sending her home, this inflammation, involving the cartilage of the auricle, had made its appearance. It started first in the concha, and then spread over the entire auricle, seeming to involve as it were a segment at a time. A number of incisions had been necessary and they had invariably been kept open by packing. There would undoubtedly be some deformity of the auricle, but he trusted that by keeping the pus well drained this would not be very extensive.

Seborrheal Eczema.

Dr. E. H. Shields presented a woman who had been shown at a meeting of the Academy several months ago, and in whom at that time he had made a diagnosis of lichen ruber planus. He had had reason subsequently to change this diagnosis to seborrheal eczema. The patient at this presentation seemed to have entirely recovered.

Sarcoma of Testicle and Scrotum.

Dr. J. Ambrose Johnston showed a specimen. The history was as follows: Mr. F., aged 50 years, had noticed a gradual enlargement of his left testicle for about two years, associated with paroxysmal attacks of pain. Recently he had noticed a beginning enlargement on the right side. The shape of the scrotum was, on examination, very similar to that of hydrocele; light, however, was not transmitted. Insertion of a hypodermic syringe drew off a dark, bloody fluid. When the patient came to operation it was found that the skin and tunica vaginalis were about half an inch in thickness, and the testicle was cystic; in size, three inches in one diameter and two in another. An incision was then made over the right testicle and the same condition, only less extensive, having been found, it was decided to remove both and the scrotum as well, the entire mass having an appearance of malignancy. This was done, and the cords ligated with catgut as high up as possible. The patient made an uneventful recovery. Microscopic examination revealed that the sarcomatous infiltration had involved both the tunica vaginalis and the skin in addition to both testicles.

Congenital Abnormality of the Small Intestine.

Dr. J. C. Oliver presented a specimen and report of a case. Soon after the birth of the infant it was given a small dose of castor-oil. This was vomited. No movement of the bowels occurring, the dose was repeated the following morning, and was again rejected. An injection was then given and a piece of black, hard material, coated with mucus, was passed *per anum*. For about forty-eight hours the patient was in charge of a midwife, but no passage from the bowels occurring during this period, Dr. B. P. Goode was called in. Dr. Oliver saw the child about eight hours afterward, with Dr. Goode. It had not nursed for twenty-four hours, and the abdomen was somewhat distended. The nurse in charge insisted that some gas had been passed from the rectum and, relying on this statement, a small quantity of senna and rhubarb was given. Returning the next day, he was informed that every dose of the cathartic had been vomited, and that the vomit had now assumed a fecal character. Examination of the rectum showed that no obstruction existed at this point, so the child was prepared for abdominal section. On opening the abdomen and examining the bowel, a dilated portion of the small intestine ending in a blind pouch was found; beyond this was a layer of tissue resembling the mesentery, but possessing no bloodvessels and about 1¼ inches beyond the termination of the bowel described above was the beginning of another portion of the bowel; this began as a blind pouch and had no communication with the bowel above. As the intestinal caliber was too small to accommodate a Murphy button, end-to-end anastomosis was made. Death followed in about five hours. Postmortem examination showed that the defect existed at the lower end of the ileum, about two inches above the junction with the head of the colon. The small intestine above the obstruction was greatly dilated, while that below, as well as the large intestine, was collapsed and empty. The specimen also showed that in spite of the fact that death had occurred within five hours after section, Nature had rapidly proceeded with healing; the water trial showed that union was firm and that there was no leakage. The remaining portion of the intestinal canal was normal.

Ovarian Cyst with Twisted Pedicle.

Dr. Rufus B. Hall presented specimens of intrapelvic disease with histories, one being an ovarian cyst with acute twisted pedicle, with peritonitis, operation and recovery. The patient, aged 40, having been informed by her family physician that she had a tumor, consulted him about having it removed. She lived a number of miles outside the city, and asked for a few days to complete some family arrangements before coming to the hospital. Up until the time she entered the hospital she was on her feet a great deal, and at the time of her entrance complained greatly of abdominal pain; her pulse and temperature were, however, normal. The operation had been set for the fourth day. During this time she became steadily worse, though her symptoms were not serious until the morning of the day determined on for operation. He had no doubt at that time that the pedicle of the freely movable tumor had become twisted. On opening the abdomen he found a cyst, perfectly black; this tapped, yielded more than a gallon of blood-stained fluid; a portion of the tumor, about as large as a cocoanut, was solid. The pedicle was long, narrow, and twisted three times upon itself; the venous supply was entirely cut off, but not the arterial. The result of this was that many of the veins lining the tumor had become gradually distended until rupture had occurred. There was at least three pints of blood-stained ascitic fluid within the general peritoneal cavity. General peritonitis of high grade was also present. The tumor was removed without difficulty, the abdomen thoroughly drained with normal salt solution, a glass drainage tube inserted—removed in thirty-six hours—and the wound closed. For two days her life was despaired of, but at the end of that time she began to rally and from then her convalescence was uninterrupted. She was discharged well in four weeks.

NEW YORK ACADEMY OF MEDICINE.

January Meeting of the Section on Pediatrics.

Infantile Colic.

Dr. H. Illoway, in a paper on this topic, said that the principal causes of infantile colic are flatulence, influences acting through the mother, indigestion, and refrigeration. Slow or imperfect indigestion will cause flatulence, and constipated mothers are apt to have constipated nurslings. It is generally recognized that indiscretions in the mother's diet often inflict much misery on her nursing infant, but it is less generally understood that salts, senna and similar purgatives, even when taken in such small doses as to fail to exhibit their action in the mother, may cause colic in the nursing infant. Changes in the breast milk, arising from mental worry, sudden emotion or sexual excitement, occasionally affect the infant profoundly, and the possibility of their occurrence should be borne in mind. An obstinate colic has been known to resist all treatment until the mother has been relieved of a toothache from which she has been suffering. The physician will often be misled in his efforts to elicit a history of overfeeding or of too frequent feeding unless he makes pointed and persistent inquiry. Refrigeration is an important causative factor, and generally arises from the infant being allowed to lie in a wet diaper, or in a draught or sit on a cold floor. An important point in the differential diagnosis between simple infantile colic and that dependent on grave pathologic conditions is that in the former the little one kicks and cries and then relaxes into a smile. An excellent means of relieving the colic is irrigation of the lower bowel with hot water, and the external application of heat. Of the many remedies recommended, he has found none superior to freshly prepared milk of asafetida, given in a dose of one-third to one-half teaspoonful, and repeated in fifteen or twenty minutes if required. If given with a little fine sugar, on a spoon, few babies will refuse it. Hiccough is often quickly relieved by putting a few grains of fine sugar into the infant's mouth. The treatment will include the removal of the cause as well as the relief of pain, and one should be slow to resort to opiates in a case of protracted colic.

Dr. Thomas S. Southworth remarked that many babies who are thought to be colicky are only petted and spoiled ones. By regulating the mother's diet and the intervals of nursing, and insisting that she take more out-door exercise, most cases of colic in the nursing infant can be satisfactorily treated. An important step is the personal examination of the stools.

ORLEANS PARISH MEDICAL SOCIETY.

Meeting held February 9,

Bony Outgrowth from Clavicle.

Dr. E. Moss read a report of a case of bony outgrowth from the clavicle, in which a diagnosis of sarcoma was made on the first examination. Two weeks of antisyphilitic treatment caused a rapid diminution in the size of the growth, which ultimately disappeared under a continuance of the same treatment.

Peculiar Symptoms in Influenza.

Dr. A. Nelken reported a case of influenza presenting peculiar symptoms. The patient had, with some elevation of temperature, enlargement of the cervical glands and a throbbing pain in the chest, which was ascribed to enlarged mediastinal glands pressed upon by the large vessels in their vicinity.

Case of Delayed Bowel Action.

Dr. J. Barnett reported the case of a woman who usually had but one fecal evacuation in two weeks, and that so small as to be entirely out of proportion to the ingesta. He was inclined to believe that hers was a case not of retention of feces in the alimentary tract, but of unusually good absorptive powers, with little of the ingested substances being left for evacuation.

AMERICAN.

3. **Cavite Fever.**—Wright describes the form of a disease which seems to be endemic in certain localities of the Philippine Islands, characterized by abrupt onset, high temperature, severe muscular pain, extremely painful and tender eyeballs. The predisposing causes are high temperature, low damp localities, overcrowding, and possibly the nearness to salt water. The exciting cause is supposed to be microbic, though it is as yet unknown. No deaths have occurred and the pathology is obscure, but the author seems to think it due to a toxic peripheral neuritis. The disease is most apt to be confused with dengue, but the absence of an afebrile period and rash enables one to differentiate it from that disease. The absence of catarrhal symptoms separates it from epidemic catarrh. The treatment is rest in bed, with liquid diet, free opening of bowels and cold-tar antipyretics and quinin. In some cases it has been followed by local atrophy and paralysis.

4. **Exophthalmic Goiter.**—Three cases are reported by Abrahams, which seem to point to syphilitic infection as a precedent to Graves' disease. He thinks that the specific affection is not a mere accident or coincidence. The old idea which charges exophthalmic goiter to a disturbance of the cervical sympathetic should receive attention only after syphilis has been excluded, and those cases which yield to mercury or the iodids be looked upon as of syphilitic origin. All the cases where the orthodox remedies fail should be put to the test of specific treatment, and also those characterized by gangrene of the extremities, pigmentation or nocturnal headaches or other suspicious symptoms.

5. **Carbuncle of the Lips.**—Powers calls attention to the danger of inflammatory local disorders in the region of the

derstood that salts, senna and similar purgatives, even when taken in such small doses as *to fail to exhibit their action in* the mother, may cause colic in the nursing infant. AMERICAN.

3. **Cavite Fever.**—Wright describes the form of a disease which seems to be endemic in certain localities of the Philippine Islands, characterized by abrupt onset, high temperature, severe muscular pain, extremely painful and tender eyeballs. The predisposing causes are high temperature, low damp localities, overcrowding, and possibly the nearness to salt water. The exciting cause is supposed to be microbic, though it is as yet unknown. No deaths have occurred and the pathology is obscure, but the author seems to think it due to a toxic peripheral neuritis. The disease is most apt to be confused with dengue, but the absence of an afebrile period and rash enables one to differentiate it from that disease. The absence of catarrhal symptoms separates it from epidemic catarrh. The treatment is rest in bed, with liquid diet, free opening of bowels and cold-tar antipyretics and quinin. In some cases it has been followed by local atrophy and paralysis.

4. **Exophthalmic Goiter.**—Three cases are reported by Abrahams, which seem to point to syphilitic infection as a precedent to Graves' disease. He thinks that the specific affection is not a mere accident or coincidence. The old idea which charges exophthalmic goiter to a disturbance of the cervical sympathetic should receive attention only after syphilis has been excluded, and those cases which yield to mercury or the iodids be looked upon as of syphilitic origin. All the cases where the orthodox remedies fail should be put to the test of specific treatment, and also those characterized by gangrene of the extremities, pigmentation or nocturnal headaches or other suspicious symptoms.

5. **Carbuncle of the Lips.**—Powers calls attention to the danger of inflammatory local disorders in the region of the

lips, and the risk of thrombosis of the facial veins extending to the cerebral sinus and causing facial pyemia. The only remedy in such cases is *prompt excision,* through the mucous surface of the lip, if possible.

8. **Post-Operative Hernia.**—The cure of post-operative hernia is only by operation, and Haynes suggests the following practical directions: 1. Make the incision in each side of the old scars in the healthy skin, though large surfaces must be incised. 2. Look for and recognize the various muscles of the facial planes at a distance from their cicatricial involvement and incise the layer in normal tissue. 3. Divide the peritoneum far enough from the cicatrix so that its normal tissues are easily recognized. 4. Sever adhesions of hernial sac to the viscera or omentum, between ligatures when necessary. 5. The omental stump is to be covered up by rolling into the omentum and keeping it there by running sutures of free catgut. The deeper sutures of the intestines should be covered by bringing the peritoneal coats together, thus preventing subsequent adhesion. 6. Close the wound with chromic catgut after all oozing has been arrested. Unite the peritoneum with a No. 0 chromic gut; the muscular layers by a No. 1, if they are thin and weak, and a No. 2 if thick and strong. The fascial layer is to be closed by a continuous suture or interrupted stitches of No. 1 chromic, and the skin by a No. 0 applied subcutaneously. The wound is to be protected by a light dressing and supported by rubber adhesive bands. Rest in bed for at least three weeks should be observed to give the union sufficient strength. No truss should be used afterward.

9. **Dietetic Management of Typhoid.**—Inglis protests against the use of milk as a diet in typhoid. It is not to be considered as a liquid diet for, after its introduction into the body, it becomes solid and the best kind of culture-medium. The fear of starvation is useless, the ideal diet for typhoid fever is pure water in abundance. This will keep up the excretions by the skin, lungs, kidneys and liver, and the elimination of poisons is a necessity. The bowels then being emptied become open to antiseptic treatment. Later, to satisfy friends and others, he would give such foods as are most easily digestible and absorbed in the stomach, keeping in mind that while the stomach may be acting poorly the intestines are worse. Tender lamb chops and poached eggs are better than milk. He speaks strongly against the use of alcohol as a stimulant; he gives a small drink of good coffee instead, which is more permanent in its effect and may be given with cream and sugar, Sugar, he considers a valuable diet, highly nutritious, while no other hydrocarbon is more promptly and easily absorbed, and the typhoid patient can take it up rapidly.

10. **Sudden Death in Pleurisy.**—Allen reports a case of sudden death in pleurisy and discusses the mechanism of such cases, giving the opinions of authorities. This case, he thinks, can be best explained by assuming that a fleck of fibrin was absorbed from the area of fresh pleurisy in the right lung, carried to the pulmonary vein and lodged there, thus producing a gradual thrombosis causing fatal termination several hours later. This case certainly lends no support to the theory of vascular kinking, since, though the adhesions were very extensive, there was no contraction of the chest and the heart was not displaced.

12. **Digitalis.**—Solomon first describes the constituents of digitalis and their therapeutic standing. As regards the choice of digitalis preparations, he enumerates the various requirements as follows: 1. Should the effect be immediate or slow? 2. Is cardiac action chiefly desired? 3. Is diuretic action wanted? 4. Should the action be both cardiac and diuretic? But one preparation of digitalis fully represents the drug, that is the powdered leaves. In the tincture containing digitalin and digitoxin the action is chiefly cardiac and slightly diuretic; the infusion containing little if any digitalin or digitoxin, but considerable digitonin, as well as some digitalein, is the best diuretic preparation. In prescribing the tincture it is well to remember that the addition of water modifies the virtue of the preparation by precipitating the contained digitoxin. If water is taken with the dose, any precipitate that settles at the bottom should be swallowed. As regards its physiologic action he calls attention to certain fallacies, viz., the estimation of the effects of the drug from experiments on healthy animals as compared to those on diseased individuals. All drugs have more or less specific or selective action in disease, frequently sometimes in different diseases. This has been shown to be so in cases with digitalis. We are taught that this drug is indicated where there is failure of dynamic power of the heart, especially if at the same time the arterial tension is low, but it is surprising, and this point must be emphasized, what benefit follows the administration of the drug in cases where on theoretical grounds it would seem best to avoid it. This is so not infrequently in aortic regurgitation. The nitrites, especially nitroglycerin, often make an admirable addition to the drug in cases where it is apparently contraindicated, and permit it to be used where it would otherwise be impossible. The cumulative action may be entirely avoided by carefully watching the diuresis and by the administration of the drug as longer intervals. Occasionally it is well to skip a day or two. The relative cardiac and diuretic action of the digitalis derivatives is noticed. Digitophyllin has been used to a very limited extent. Its action resembles digitoxin and it may some day come into general use. On the heart and circulation in general the three digitalis glucosids, digitalin, digitalein, and digitoxin, have effects much in common, though there are certain well-defined differences. All three are true heart stimulants, but digitalin is unique in its special influence on the vasomotor center, medulla, and ganglia in the muscular coats of the blood-vessels, contracting them and raising the arterial pressure. It also slows the pulse by directly stimulating the cardiac ganglia. Digitalein and digitoxin do not directly raise arterial tension and slow the pulse, but they do dilate renal blood-vessels, increasing the flow of the urine, and in this respect their therapeutic value is great, especially in cardiac affections accompanied by low arterial tension. The author contrasts digitalin and digitoxin, the latter being the chief ingredient in the leaf, which should be standardized in the treatment of its contained digitoxin. It is superior to digitalin in its diuretic action. Its action is prompter and more certain and it is less liable to cumulative action. He thinks it has the brightest future of all the digitalis preparations and in combination with nitroglycerin acts admirably. A number of cases are reported showing the cardiac and other conditions in which the drug has been used by the author.

14. **Uremia.**—Jelks calls attention to the fact that uremia may occur in persons with perfectly sound kidneys. The functional activity of this organism may be so affected that uremic symptoms arise. He notices the methods of examining for solid constituents and reports a number of cases of cardiac and other symptoms apparently connected with functionally, etc., insufficient excretion.

16. **Epidural Hemorrhage.**—The diagnosis of this condition is most important, and the symptom which is well nigh pathognomonic, as pointed out by Horsley, is the interval of consciousness between the time of injury and the first cerebral symptom, which may last for a few minutes or many hours, depending on the severity of the injury. Epidural hemorrhage frequently exists without such interval, but this class of cases will be found complicated with some trauma of the brain. Other important signs are injury to the scalp, if only a slight contusion, inequality of pupils, gradual appearance of coma heralded by stupor; early convulsions point to the seat of pressure. It takes a considerable amount of blood to cause sufficient pressure for cerebral symptoms and usually a number of centers are involved. The hemiplegia and paraplegia come on gradually according to whether the hemorrhage is at the side or top of the brain. Epidural hemorrhage at a distance from motor centers is not likely to cause convulsion or paralysis until it causes general compression and localizing symptoms which should be looked for. Breathing is slow, the pulse usually slow and full, later becoming rapid and weak, the temperature subnormal, and cases without fracture and contusions and of sufficient severity should be operated on as soon as possible under favorable circumstances. The author reports a case.

17. **Closure of Cutaneous Wounds.**—The following method is advised by Lilienthal for closing skin wounds or other eruptions so as to avoid infection, stitch abscesses, etc. The deep layers of the wound are closed with various materials, but the wound of the skin is covered with sterilized gutta-percha and the edges approximated with India rubber zinc plaster. He has had no infection in these cases, notwithstanding the plaster he had used was not considered aseptic, but has had one made recently by Johnson & Johnson, sterilized and kept in a sterilized container. When applying the plaster one must be careful to check all hemorrhage and to dry the skin thoroughly with alcohol or ether. The strips are then laid on. The method should not be used where there is tension. It is applicable in partial closures when drainage is employed. On the fifth or sixth day the strip should be removed by loosening both ends, drawing them toward the wound.

18. **Tracheal Injections.**—Murray calls attention to the method of introducing remedies by tracheal injections. The curved canula of the syringe is passed between the vocal cords, slowly injecting the fluid into the trachea, the Schadel syringe being used. He gives Mundell's prescription for injection, consisting of 5 grams each of the essences of thyme, eucalyptus, and cinnamon, with 100 c.c. of sterilized olive-oil, 3 c.c. being injected three or four times consecutively. The usual first effect of the injection is slight explosive cough. Out of thirteen cases treated during the past seven months all but three have been decidedly benefited; cough and expectoration have been lessened and temperature lowered. In no case has he seen glottic spasm follow the injections. The antiseptics used enter at once into the field of their labor, and penetrate to the farthest limit of the respiratory space, coming into immediate contact with the toxins as they are generated. While he says he does not undertake to estimate the full value of the treatment he thinks it may be fairly said that it does lessen the cough and expectoration and improve the general condition.

20. See abstract in The Journal, xxxv, p. 1172.

32. **Suprarenal Capsule.**—Bates emphasizes some facts already published and calls attention to the use of suprarenal capsule with its hemostatic action in operations on the eye, ear, nose and throat, urethra and uterus. He concludes his paper by saying that suprarenal extract is the most powerful known hemostatic and when properly used has no objectionable properties. When it is used locally, hemorrhages from the mucous membrane can always be controlled. Its internal use as a hemostatic is sometimes efficient. When it controls hemorrhages locally or otherwise its effects are noticeable in less than a minute from its administration. The dried powdered gland, he thinks, is the only preparation for internal use.

22. **Appendicitis.**—Miller maintains that there is a reaction taking place against the exclusively surgical treatment of appendicitis. That cases have occurred under surgeons where the appendix was found healthy speaks strongly against the too universal and indiscriminate operation. He thinks sufficient stress has not been placed upon the point of dulness and in every case in his experience, where he has relied upon this symptom, he has been led to a correct conclusion. In cases without any pronounced inflammatory symptoms, in which dulness was marked, he found the appendix indurated and adherent. Twenty cases are reported which show the significance of this symptom.

23. **Gonorrheal Infection.**—Tenney first notices the nonspecific discharges and then passes to the question of actual gonorrheal infection. He emphasizes the importance of the persistence of the infection and does not hold that there is much danger of infection without any visible discharge for months. He discredits Noeggerath's and other estimates as to the extreme frequency of gonorrhea.

24. **Bacteriologic Diagnosis of Gonococcus.**—The most important precaution in examining for the gonococcus, according to Richardson, is to smear the pus properly on a cover-glass; usually it is too thick. Another important precaution is to be sure that the anilin oil gentian-violet has not decomposed. In examining for the organism in inflammatory processes other than gonococcic conditions, something being more than a cover-glass examination and the application of the Gram's method of staining is needed. The suspected microbe must be isolated in pure culture, its peculiarities found to agree with the known pictures of the gonococci, and the micrococci composing such colonies must be tested by the Gram's method and have a decided tendency to group in fours. The test of the behavior of the cocci so isolated, toward the Gram's method, is of great importance, and is to be applied with certain precautions: 1. The cultures must be over forty-eight hours old. 2. The cover-glass preparation must not be too thick. In short, no culture is to be regarded as a culture of the gonococcus unless the organism occurs only in special media, decolorizes by Gram's method and shows a decided tendency to grouping in tetrads.

33.—See abstract in The Journal, xxxv, p. 1685.

34. **Parasites in the Blood.**—Le Wald notices the *filaria*, recognizing the three forms, nocturna, diurna, perstans, and the plasmodium malariæ, the peculiarities of which are briefly stated.

35. **M. S. Mixture.**—The title of this article defines the mixture. Adams concludes that its chief advantages are: 1. State of excitement and struggling are not marked. 2. It requires a short time to get a patient under, five or ten minutes. 3. Very little of the anesthetic is required. On an average about 40 c.c. are used in an hour. 4. It is a comparatively safe anesthetic. 5. It is very pleasant to take. 6. The after-effects are not marked. 7. Patients recover quickly. 8. It can be used in nearly every condition in which either chloroform or ether is employed.

37. **Insanity.**—Beebe discusses the conditions and symptoms that constitute insanity, basing the diagnosis: 1, upon the state of feeling—emotions; 2, upon the reasoning faculties—intellect; 3, upon the power to do or not to do—volition—the proper balance of these three being sanity. The due consideration of these will establish the fact whether the patient is in a state of mental daylight, twilight, or darkness.

38. **Spinal Anesthesia.**—Whitacre reports four cases of spinal anesthesia in which the method was successful and the by-effects not serious. The dangers, he thinks, are the possible mortality which may result from a toxic effect of the drug upon the respiratory or cardiac apparatus or from the production of thrombi or emboli which may result from infection, or from the too rapid withdrawal of the cerebrospinal fluid. Symptoms of poisoning or depression may occur short of death, and in quite a majority of cases severe vomiting has been noticed. The method never can be applied in certain classes of patients, i. e., nervous women and children, where consciousness of the operation will enhance the shock, and there is little probability that it can be applied to the higher portions of the spine without permanently increasing the dangers. On the other hand, there are a large number of cases where renal, cardiac and pulmonary disease exists, in which this method is far less dangerous, even with our present knowledge, than general anesthesia, and he also believes that the method will be perfected, giving us a less toxic drug with equal efficiency. Other advantages are that the patient can often give valuable aid during the operation and can be consulted in regard to more extensive measures than were originally intended. The usual after-effects of ordinary anesthesia are generally absent and shock in the properly selected cases is less than often occurs after general anesthesia.

39. **Unclean Mouths.**—The dangers from mouth bacteria in producing dyspeptic and other symptoms are noticed by Fletcher, as also the dangers from more virulent organisms. The mouth can not be kept absolutely clean from disease germs, but they can be gradually reduced in number by hygienic treatment, securing the best possible development of the teeth and glands, the use of antiseptics and the prohibition of consumption of such foods as specially foster the growth and development of fermentative and putrefactive germs. The

fermentation of carbohydrates is specially noticed as the cause of acid fermentation, destroying the teeth and favoring bacterial growth. We can not disuse them altogether, but they can be reduced to a minimum. He thinks that the alkaline antiseptics are absolutely necessary to properly cleanse the mouth and should be applied to it at least twice a day, even in the best conditions, and two or three times as often with the majority of persons.

42. **Seborrhea.**—After noticing the views of authorities on the subject, Loth endorses the opinion of Elliot that the only true seborrhea is the condition usually referred to as seborrhea oleosa, which may occur not only on the scalp but also on the face, sternum, interscapular and genital regions. Any inflammatory process which would develop on such a surface would be characterized by features of true seborrhoic eczema and syphilitic or psoriatic lesions similarly modified. Seborrhea does not produce eczema, but acts only as a predisposing factor. The conditions known as seborrhea sicca, pityriasis capitis, seborrhea corporis, etc., are all degrees of seborrhea dermatitis. We have merely clinical grounds for believing that these affections are parasitic in character. These are the circinate character of the lesions, their marginate outline, peripheral extension while clearing in the center, the evidence of infection derived from brushes used by a person having the disease, the spreading from one member of a family to another and the response to antiparasitic remedies.

43. **Trigeminal Neuralgia.**—Hughes protests against too much surgical treatment of trigeminal neuralgia and in forty years' practice in cases that he has had the chance to steadily treat, he has yet to see the first go to the surgeon. His chief reliance in neuralgia, especially sciatica and facial, has been on belladonna or atropin, strychnin, large doses of quinin and more recently hypoquinidol, which is a phosphate of quinin. He has also supplemented this with persistent galvanization of the affected nerve tracts and some form of bromid, the hypophosphites of iron, and gelsemium in green root tincture for direct anodyne effect. He uses locally, ether, menthol, heat and electricity. In many cases also he has used Fowler's solution and coal-tar anodynes. In neuralgia there is a peculiar state of special aptitude to pain in the nervous system; there is weakness and proneness to become affected by cold, etc., that would in other cases be harmless. He draws the line on uterine diseases as the direct cause, not attributing neuralgia to them. As regards surgical operations, he is conservative. He thinks that the complete removal of the Gasserian ganglion should be undertaken only as a last resort. He objects to this procedure: 1. Because of the curability of the disease by medication if rightly employed, in many cases where sufficient vital stamina remains, such as would withstand the ordeal of ganglion extirpation. 2. Because trifacial neuralgia is not a disease exclusively of the ganglion. 3. Because it appears to be a disease not confined to the fifth nerve or the beginning at the Gasserian ganglion. It is a morbid state of the sensory nervous system with characteristic trigeminal manifestations and not exclusively a local disease. 4. Because as good an effect can be obtained by rest and recuperation. 5. Because of the trophic irritative or paralytic sequelæ in the cornea and face, the herpes, ear and jaw involvement, ptosis and fourth and sixth nerve paralysis and, finally, the mortality of operation in some cases. The infection which follows the perforation of the antrum, and the shattered health of many surviving also seem to forbid it. The fact that power of tension of the tympanum comes from the fifth nerve and otic ganglia is not considered as it should be by surgeons. His suggestion for a neurosurgical plan of successful treatment of trifacial neuralgia when neurotherapy fails would therefore be this: Mentally prepare the patient for its radical relief by securing hopeful consent to a combined surgical and neurologic treatment. Put her or him in bed, give chloroform, extirpate the involved peripheral nerves if you wish, keep both the eyes closed—not necessarily by stitching—for the same length of time as one is kept closed by stitching to prevent the eye sloughing, so likely to follow Gasserian ganglion extirpation without it. Keep the eyes closed to secure brain and nerve center rest. Keep visitors away from the patient, maintain absolute brain and neural quiescence, such as follows the operation, by appropriate medication, and maintain at least a six to ten weeks' treatment on the lines above indicated. With this plan put in faithful practice he thinks Gasserian gangliotomy would take its place among the lost arts.

45. **Tubercular Peritonitis.**—From a study of the literature, Neff concludes that tubercular peritonitis is a disease to be treated surgically by laparotomy, rapidly and carefully performed. The danger is slight, the mortality being less than 3 per cent. As regards the theory of the curative effect of laparotomy, he thinks the antitoxin theory of Gatti the most rational, though several of the various assigned causes may combine. Sepsis is not apt to occur on account of the pathologic changes that have taken place in the peritoneum, and tubercular infection of the wound is always absent. Antiseptics are useless and drainage should be avoided for its tendency to permanent fistula. Most of the deaths after the operation have been due to a general tuberculosis or tuberculosis of some other part. The successful treatment of this condition depends on the diagnostic ability and good judgment of the surgeon.

48. **Jamaica Ginger Amblyopia.**—Dunn reports two cases of this condition, the only previous cases that he has learned of being those of Thompson and Woods. See The Journal, xxxvi, p. 34.

58. **The Esophageal Glands.**—Two varieties of these glands, the submucous, which has already been recognized, but the other variety entirely distinct from this, are described by Hewlett, from their situation as superficial to the muscularis mucosa. They occur mainly in two localities, in areas in its upper portion and near the cardiac orifice where they extend a short way toward the stomach, being replaced by typical fundus glands, and they have been grouped by some with the gastric glands. Hewlett describes the structure of these glands in detail, noticing the previous observations of Rudinger, Schaffer and others pointing out their distinction from the submucous glands and raising the question as to the possibility of their giving rise to carcinoma. He has collected six cases of adenocarcinoma of the esophagus, to see if their location bore any relation to these glands, but did not find them situated within the usual limits of the latter.

59. **False Diverticula of Intestine.**—By a true intestinal diverticulum is understood one whose walls are composed of the entire thickness of the intestine. A false diverticulum, on the other hand, is a hernia of the mucosa and submucosa through the muscular wall and consists only of mucosa and serosa with intervening connective tissue. It is also desirable to distinguish between congenital and acquired diverticula, but the false are always acquired. Their etiology is somewhat obscure. Traction has been suggested, but it is not generally accepted as the cause. For a long time it was held that they were due to increased intestinal pressure, feces, gas, etc. Klebs has suggested that they may occur with growth of the mesentery, in length outstripping that of the blood-vessels, or more probably with traction in later life upon the mesentery by the intestine. The funnel-like attachment of the ventral wall to the entering mesenteric vessels becomes converted into diverticula. The greater frequency of intestinal diverticula in elder and obese persons supports these later views. Other authors have attributed the origin of diverticula to "pulsion" rather than traction and Hansemann has defined more precisely the vascular relationship. It has been shown by Heschl that the intestine ruptures under pressure at the point where the diverticula are found. Experiments by Good and Hanau have produced the same formations. Senility favors these conditions and various other etiologic factors favor the normal lessened resistance. Chronic constipation may be considered a predisposing factor. Fatty degeneration of the muscularis has been mentioned. Separation of the muscular fibers of the duodenum by the common bile-ducts favors diverticula in that part of the duodenum, stenosis leading to increased intestinal pressure and in general sluggishness of the intestinal

functions may produce it. These are factors unconnected with clinical symptoms and only discovered postmortem, but in some cases pathologic processes have followed, such as ulceration and inflammation due to filling of the diverticula with feces, peritonitis, etc. One of the favorable terminations is an increase in the connective tissue element, but this is rare in these acquired formations. Fischer reports and discusses a number of cases of interest as bearing on the etiology and pathology.

62. **Islands of Langerhans in Chronic Pancreatitis.**—The conclusions of Opie's article are: 1. That congenital syphilitic pancreatitis retards the development of glandular acini but does not affect the islands of Langerhans. Embedded in the stroma, but not invaded by it, the latter maintain their continuity with the small ducts and acini with which they have a common origin. 2. Two types of chronic interstitial inflammation affecting the development are distinguished: *a.* Intralobular pancreatitis localized chiefly at the periphery of the lobule implicating the islands of Langerhans only when the sclerotic process is very advanced. In pancreatitis following obstruction of the ducts the islands long remain unaltered though embedded in dense scar-like tissue. *b.* Interacinar pancreatitis. In this type the process is diffuse, invading the lobule and separating individual acini; the inflammatory change also invades the islands. 3. Relation has been observed between lesions of the islands of Langerhans and the occurrence of diabetes mellitus. In one out of eleven cases of intralobular pancreatitis mild diabetes occurred. Sclerosis in this case followed obstruction of the ducts by calculi and was far advanced and affected the islands of Langerhans. 4. In two of the three cases of intracinar pancreatitis diabetes was present. The third case was associated with hemochromatosis, which at the latter stage is associated with diabetes from pancreatic lesions. In the fourth case of diabetes, hyalin deposit between the capillaries and the parenchymatous cells had so completely altered the islands of Langerhans that they were no longer recognizable.

66. **Spinal Tuberculosis.**—Wiener insists on the importance of early diagnosis of the treatment and the need of paying special attention to reflex spasms of the dorsal muscles. The conventional plaster-of-Paris jacket should not be relied on. Permanent extension is the reliable measure. He does not think much of forced correction of the spine in tuberculous deformity unless in cases where the deformity is of recent date.

67. **Addison's Disease.**—Willson reports a case of Addison's disease and discusses the pathology and symptoms. He thinks that the symptoms are best accounted for by the combined effects of suprarenal inadequacy, and sympathetic irritation, either functional or organic. He compares adrenals in their influence on the system to the sexual glands, both atrophying in old age and raising blood tension.

70.—See abstract in The Journal of January 12, p. 126.

80. **Syphilis and Associated Affections.**—The relation of syphilis to other disorders is stated by Bulkley, who recognizes that various affections may complicate a specific disease. There may be a simultaneous or successive infection, but there is need of more definite microscopic studies in regard to the ordinary infections of specific lesions. As regards infection of general disease, he finds that variola seems to aggravate syphilis while it exists, according to some observers, and others have seen syphilitic lesions disappear during the course of smallpox. The testimony, therefore, is somewhat varying. As regards erysipelas there is some evidence that it has a counteracting effect on syphilitic virus. There is, however, a lack of experimental and clinical observation. Measles and scarlatina seemed, according to Mauriac, to hasten the eruption; typhoid may temporarily affect specific eruptions. The subject is worthy of further observation. Other disorders like syphilis and malaria, syphilis and diphtheria, tuberculosis, lepra, and sepsis are all noticed. Bulkley concludes that in erysipelas there seems to be an antibiosis, as cases are recorded where erysipelas appeared to be curative. The toxins of some of the other infectious diseases seem to have some effect in arresting the progress of syphilitic lesions in their early stages, but as their effects pass off the virus reasserts itself. Metabiosis, where one organism prepares or paves the way for another, seems to be indicated in malaria, as it temporarily renders the subject peculiarly liable to severe symptoms in syphilis. Symbiosis where the two morbid actions assist each other, is illustrated by tuberculosis. Lepra and septic conditions aggravate both primary and later manifestations, and many cases are recorded where the pus-producing micro-organism was found in connection with syphilitic lesions. He suggests that it is worth considering whether the unusual severity of certain cases is not largely due to mixed infection. The paper concludes with a lengthy bibliography.

81. **Wheal Lesions in Syphilis.**—The absence in American literature, of mention of the wheal type of syphilitic lesions, is noticed by Klotz who reviews certain authorities and his own observation showing that such do occur. The appearance of wheals is generally supposed to be due to an angioneurosis, but the author suggests the embolic process which would account not only for the appearance of patches of syphilis but for the primary localized syphilis, for which, heretofore, we have not been able to offer a satisfactory explanation.

82. **Unusual Phenomena of Syphilis.**—Zeisler reports a case of othematoma occurring without any known cause, in a physician who had been accidentally infected with syphilis. It promptly disappeared under administration of iodid of potassium, without causing any injury, save a slight thickening of the cartilage in the locality. About six months after the occurrence of this accident the patient had symptoms of Meniere's disease and has since had peculiar nervous phenomena, which possibly suggests some pathologic alteration at the base of the brain. Zeisler suggests, therefore, the possibility of othematoma being due to some central origin.

97. **Bromids.**—Clark regards bromids only one of the many drugs to be employed in epilepsy, but it is the one par excellence for treating the seizures. The formula which he considers the best is the elixir of the triple bromids, containing 5 gr. each of potassium bromid, ammonium bromid, and sodium bromid to a dram of simple elixir. Every possible precaution to prevent brominism must be taken. The organism must be kept at the highest functional state; hot and cold baths, massage and electricity should be given. He orders prolonged hot baths in patients in good condition, twice each week on retiring, and a cold shower bath and a friction rub every morning on rising. He allows coffee, but no alcoholic stimulants in connection with these cold packs. The bowels must be watched, mouth kept clean, and any signs of bromid intoxication be promptly treated. When the bromid salts can not be given in high doses, he uses the bromids and bromin in emulsion, which is less irritating to the intestinal tract, not constipating and less toxic. It also seems more lasting in its effects. The greatest adjunct to the bromids, however, he thinks is the method which he calls hypochlorization or salt starvation. This was introduced by Toulouse and the *rationale* is simply to substitute bromin for chlorin in the tissues, both chemically and physiologically. Linossier, in investigating the subject on animals, found that bromhydric acid should be substituted in the stomach for chlorhydric acid. Bromin is not a foreign substance, but is a true mineral substance of the body. It is difficult, however, to get epileptics to discontinue salt altogether, so semistarvation of salt is all that can be expected of them. Bromid is taken into the system more readily as salt is dispensed with. One of the best and easiest ways of carrying out this adjunct of bromid treatment is the establishment of a milk diet with occasional removal to a mild salt diet, and Clark gives a dietary modified from Toulouse. Cases are quoted, and in conclusion he summarizes as follows: 1. Bromids still hold a very prominent place in epileptic treatment. 2. Tonics must be given constantly while administering bromids. 3. Bromid salts should be given gradually to find the epileptic's sedative level. 4. Baths, high enemas, alimentary antiseptics, massage and electricity are absolutely essential to successful bromid medication. 5. Bromin is a worthy successor to bromid in many cases. 6. Salt or semisalt starvation is a great adjuvant to the bromid treatment.

98. **Rheumatic Manifestations.**—Richy advocates the use of salophen in rheumatic symptoms and reports two cases, one of rheumatic pericarditis and the other of joint rheumatism treated with this drug, beginning with 10 or 15 gr. and gradually reducing the amount. He also finds this almost a specific in influenza. He has also used it to advantage in headaches dependent upon rheumatic diathesis and sciatica, in tonsillitis and scarlet fever.

103. **Formaldehyde.**—The different methods of disinfecting by formaldehyde are described by Bissell, who gives a report of experiments made by himself with various cultures and sums up the application of formaldehyde to household disinfection as follows: 1. It is the most satisfactory of the gaseous disinfectants. 2. Its penetrating powers are extremely slight. 3. A certain degree of moisture facilitates its action. 4. It should always be supplemented by a cleansing process.

113. **Leprosy in Hawaii.**—Davis gives a very good description of the Molokai leper colony, which he visited in 1898; the history of leprosy in the islands, with tables of the mortality, etc., is given. He thinks the low moral standing of the natives, habits of using the same beds, clothing, and pipes, also the fact that the leper was never an outcast among them, account for the spread of the disease. Vaccination also during the epidemic of smallpox in 1852 and 1853 undoubtedly helped to spread the disease. The native Hawaiians have no special dread of the disorder and many cases are on record where natives have tried to contract the disease in order to join friends or be provided for in the Island of Molokai. As regards treatment, he is pessimistic. He finds nothing that is curative and practically no medicine is administered in the leper settlement.

119.—See abstract in The Journal, title 42, p. 403.

121. **Posterior Uterine Displacements.**—The recapitulation of Chase's article is as follows: 1. Posterior deviation with fixation from adhesion is usually a serious menace to health and often a barrier to childbearing. 2. This condition can be best treated by laparotomy. 3. After the adhesions have been severed the cure should be completed by maintaining the uterus in an anterior position: *a*, by intraperitoneal shortening of the round ligament; *b*, if this is insufficient resort should be had to anterior abdominal suspension of the uterus. 4. Experience, while not settling all points, demonstrates that efforts to maintain the uterus in an anterior position, either by ventrosuspension or fixation, are from the uncertainty of the degree and extent of the adhesion not devoid of danger in case of conception, which should be considered, and, in certain instances, guarded against. 5. Ligation or resection of the Fallopian tubes is a more rational procedure than ovariotomy for the prevention of conception and more justifiable, as it does not unsex the woman and saves her from a premature menopause and its unpleasant consequences. 6. The value of these methods of treatment of posterior deviations is amply demonstrated and their employment should be more generally adopted.

123. **Uterine Curettement.**—Moriarta considers curettement in septic and sapremic conditions as complications of the puerperal state. He specially dwells on the importance of thorough removal of infection spreading retained tissues, the necessity of careful and conscientious measures in the operation of curettement, the danger of perforation of diseased uterine wall, the chances of a long and patulous cervix leading to mistakes, and gives the details of the technique. He uses anesthesia according to the conditions, sometimes he employs it and sometimes not. After scraping and the removal of new adhesive tissue, which is done with a good-sized Rhamstetter irrigating curette, he follows it with a small-sized curette, going over the walls slowly and methodically. Following the scraping he uses a hot solution of bichlorid—1 to 2000—followed by a saline solution of sterile water; he then packs with iodoform gauze. If large quantities are needed it is well to wash it to prevent iodoform poisoning. The gauze is removed at the end of twenty-four hours and usually not replaced.

125. **Intrapelvic Hemorrhage.**—Manton reports a case of excessive uterine hemorrhage due to a pathologic new growth, a fibroma, in the lower portion of the broad ligament encroaching upward with involvement of tube and causing degeneration and destructive changes in the blood-vessels of the part.

Considerations Touching the Pathology and Relations of Diabetes. W. Howship Dickinson.—The morbid anatomy of diabetes, according to Dickinson, is as yet somewhat uncertain. We have nothing that serves to define the disease, such as the hepatization of the lung in pneumonia. The most frequent morbid appearance is extravasation of the blood in the perivascular canals of the brain. Of twenty-two diabetic patients, eight displayed this phenomenon. Other signs of morbid action are the enlargement of the perivascular canals, giving the white matter a cribriform appearance, and the abnormal contents of these leucocytes and amorphous debris. In the cord we sometimes have dilatation of the central canal. In two out of the eight cords which he had, this was present, and also a peculiar hyaline modification in the lateral parts of the gray horns. R. T. Williamson has published cases of diabetes with evidence of degeneration of the posterior column. In the liver we have certain characteristics varying from health. The organ is large, red, hard and congested and the veins contain coagula. Dickinson does not dwell on the consequential changes of diabetes, such as the inflamed states, etc., but passes to the clinical causes. He mentions emotional disturbance, anxiety, and notices that locomotive engineers are specially liable to the disease, probably owing to the anxious nature of their work. Heredity is a most prominent cause and the association of diabetes with gout or hereditary disorders is notable. The clinical association on the side of the nervous system, of loss of the patella reflex, is noted. This may be connected with some change in the cord or nerves, though morbid changes have not been found in the peripheral nerves. Peripheral neuritis has been regarded, however, as one of the results of the toxemia of diabetes and this may account for the symptom. Another nervous phenomenon of diabetes is the occurrence of excess of earthly phosphates in the urine, especially phosphate of lime, which is unexampled in any other disease. He has placed on record cases where the daily increase of lime exceeded 3 grams. Still another symptom is the peculiar dusky redness of the complexion, often seen in advanced and severe cases. The author's investigations at the Bethlehem Hospital, of the urine of fourteen out of 106 lunatics, gave appreciable reductions of copper, together with some degree of darkening with liquor potassæ, but in no case marked diabetic characters. He is inclined to think that glycosuria accompanies insanity in a slight degree, and in a small proportion of cases. We are not yet at the bottom of the pathology of diabetes; what we know points to the undoubted origin of the disease in mental causes. Its association with larger excretion of phosphate of lime, the loss of the patellar reflex and the glycosuria of insanity are significant as to its relations with the nervous system.

Hemorrhagic Diathesis in Typhoid Fever and Its Relationship to Purpuric Conditions in General. Albert G. Nicholls and G. Everett Learmonth.—A number of examples have been recorded of hemorrhagic complications of typhoid, and the authors notice the opinion of authorities in regard to these. The hemorrhagic type was first brought to notice by the earlier French school, notably by Trousseau, but the cases are exceedingly rare. They report, in elaborate detail, the history of a case with postmortem and bacteriologic examination of the blood, peritoneal cavity and kidneys. The case was atypical in that the intestinal lesions were most marked in the large bowel, the spleen was small and there was a mixed infection with staphylococcus albus. One main factor of the hemorrhages was a fatty degeneration of the basement membranes of the capillaries and the various endothelial cells, especially notable in the lungs and kidneys. They found but few cases recorded of general hemorrhagic diathesis in typhoid. As regards the positive conditions, they notice the views of Gerhardt that the hemorrhage tendency has been more frequently observed since the introduction of the cold bath treatment. A too rigid commitment of the patient to an animal diet may be an important cause, as tending to a scorbutic condition. Its appearance seems to be most common in children and early adult life. The vast majority of cases are found in those suffering from a severe form of typhoid, the patients are much prostrated, temperature high and heart weak. The anatomic lesions differ very little from those of ordinary typhoid, but the authors are inclined to credit the action of special microorganisms as having to do with the symptom. The condition is a serious one and the treatment is necessarily symptomatic.

Treatment of Typhoid Fever. FREDERICK J. SMITH.—In cases where the diagnosis is certain the author says there are two general principles of treatment: 1. Examination of the stool. 2. The appetite of the patient. He maintains that one stool should be examined every twenty-four hours during the active course of the disease, to determine whether there is undigested milk or other food, blood or sloughs which are significant, or a due proportion of feculent debris. He has made it a cardinal rule to allow the appetite to be the sole arbiter of the diet, providing vomiting, hemorrhage and abdominal distention are not present. The temperature he ignores. In the early stages of the disease, where the appetite is in abeyance the temporary administration of water as the only food has given good results. We do not know definitely just how long this should be continued, but he has kept it up for four or five days with the best results, and the wish of the patient for foor is the only reason he had for stopping it. Milk is the standby for diet when food is given, but it should be administered in a form where balling and curdling does not take place, for example liquid custard or even baked custard if broken up fine, in bread and milk, and he would allow eggs slightly boiled or poached at any stage. All commercial foods he thinks are of doubtful value. Meat, if given, should be put through a sausage machine or minced as fine as possible. The patient may be allowed to nibble stale bread to keep the jaws exercised. The foods to be avoided are those which remain in small hard particles on leaving the stomach. The quantity and time must be regulated, about once in four hours in small quantities, but the patient should not be awakened for the purpose of giving food; sleep is more important. Between meals nothing should be given but cold or hot water, as preferred. Of the complications, vomiting, as an exhausting symptoms, should be avoided if possible. Tympanites is an ominous symptom and on its discovery all foods should be stopped, excepting water. His own plan is to at once administer 2 drams of sulphate of soda every two hours until the bowels are acting freely. It usually follows constipation. He also orders an ice-bag to the abdomen, and resorts more persistently to chlorin water or salol as an antiseptic. Constipation need never be permitted to persist. He uses sulphate of soda and calomel as the usual laxatives. If the diarrhea should be excessive, he would investigate the food and stimulants; if due to indigestion, stop all food but water. If there is much sloughing material, showing signs of ulceration, the symptom is bad. He has used an enema containing opium, nitrate of bismuth and ipecacuanha. Pyrexia can be best treated by tepid sponging. He does not favor cold baths as a rule, though in some cases they may be indicated. If starvation and opium are found to be useless in hemorrhage nothing else is of the slightest use. As to drugs, he has a preliminary routine treatment, giving 2 gr. of calomel at once, following it with 1 gr. every night. Mixtures containing carbolic acid or chlorin water are given, or he gives salol in water three times a day. Of other drugs he uses practically none excepting in emergencies. Alcohol, the thinks, is unnecessary, though a little may be allowed those who are in the habit of taking it. He does not object to beer drinking. The importance of the physician giving personal attention to the question of cleanliness is emphasized, and he expresses the opinion that the future of therapeutics in typhoid will be in serum-therapy.

Intraperitoneal Method for Radical Cure of Inguinal Hernia. T. H. WELLS.—The writer describes an operation performed by Mr. Symonds, in inguinal hernia, which he sums up in seven stages: 1. An incision 2½ inches long in the linea semilunaris, ending over the external abdominal ring and passing through the skin, fat and superficial and deep fascia. 2. Deepen the upper 1½ inches through the abdominal muscles, transversalis fascia, and the subperitoneal fat, and having arrested all hemorrhage, open the peritoneal cavity. 3. Explore the sac with the finger and remove any gut. 4. Insert forceps along the palmar surface of the finger, seize the apex of the sac and invert it, bringing it out into the upper wound. 5. Stitch the sac, after giving it a couple of twists on itself to obliterate its cavity, to the peritoneum. 6. Stitch up the external abdominal ring. 7. Close the wound by bringing the structures layer by layer into accurate apposition. The advantages are its quickness, obliteration of the neck of the sac high up, the inverted sac aiding in forming a firm scar. The sac and its contents are explored and, if necessary, the sac opened below quickly and safely. The incision allows any methods of closing the inguinal canal and external ring carried out as the operator may desire.

Bulletin de l' Acad. de Med. (Paris), January 8 and 22.

Total Resection of the Stomach. J. BOECKEL.—This is the first gastrectomy done in France and the fourth on record. The operation lasted 1½ hours; the patient made a rapid recovery, was up the twenty-second and left the hospital the thirty-third day. She had previously been much emaciated by the carcinoma which rendered the resection necessary, and after its removal gained seven pounds in a month, and thirteen more in another six weeks. The stools are regular and normal. She eats the food at the family table with no restrictions except quantity, cabbage and sauerkraut. A week after leaving the hospital her lunch was veal, carrots, fried apples, wine, biscuits and grapes, with three cups of black coffee, according to a letter received from her. The removal of the entire stomach is an operation comparatively simple and the marked and regular increase in weight testifies to perfect and regular assimilation without it. Boeckel is inclined to believe that its application is not limited to cases of carcinoma. The first point in operating is to free the greater curvature of the stomach by severing the gastro-colic ligament; then to detach the upper portion of the stomach between forceps, one placed immediately above or below the cardia; this is followed by freeing the lesser curvature by severing the gastro-hepatic ligament. The lower portion is then liberated after section of the upper portion of the duodenum between the forceps. The last step is the anastomosis of the cardiac ostium with the duodenum and suture of the abdominal wall without drainage.

January 22.

Obstetric Spinal Analgesia. GUENIOT.—Spinal cocainization has been employed in 60 obstetrical cases in France. A review of these shows that the small amount of cocain required—1 cg. of cocain in a 1 per cent. solution is ample—obviates the inconveniences sometimes observed in surgical operations. This amount induces complete analgesia below the umbilicus, suppresses the pain caused by the contractions of the uterus and the passage of the child, and far from interfering with delivery, seems on the contrary to accelerate it; it imparts greater energy and regularity to the contractions and also enables the woman to make more energetic and more sustained efforts as they are painless. The analgesia lasts from seventy minutes to two hours. No serious danger for mother or child has been observed in consequence, the only phenomena of intoxication noted being cramps or slight tremor in the limbs, transient headache, slight vomiting and a slight rise of temperature. At the same time, it is best to avoid using this method of anesthesia in patients with lesions of the heart or large vessels, chronic affection of the respiratory apparatus, or disease of the nerve centers, especially brain tumors. It is also contraindicated when absolute asepsis can not be secured. Further special contraindications are extremely rapid course of delivery, frequency and energy of contractions of the uterus or exaggerated tension of the organ, or the necessity of manual intrauterine intervention. The cocain evidently has a pronounced stimulating and regulating action on the contractility of the organ. If this fact is confirmed by further experience it will give the drug a high place in obstetrics. While it acts like ergot, it does not tetanize the uterus like the latter, and leaves the cervix permeable, at least to a certain extent. The indications for obstetric spinal cocainization are four: All obstetric operations which demand anesthesia, with the exception of those requiring the introduction of the hand into the cavity of the uterus; excessively painful delivery; extremely protracted course of the latter in consequence of weakness and irregularity of contractions, and lastly, a tendency to hemorrhage from any cause, inertia of the uterus, placenta previa, etc. The decrease in the amount of blood lost during delivery is extolled by Doléris as one of the chief advantages of obstetric laparotomies, and possibly also the preservation of the mental faculties. Doléris states that he is now aiming to make parturition altogether painless, but Guéniot doubts whether this will prove an advantage on the whole.

Bulletin Medical (Paris), January 23.

Dialyzed Raw Meat. Battesti.—A process is described which converts raw meat into a bouillon containing one-third more of the nutritive substances than the same amount of chopped meat, while the stomach is completely relieved of the task of digesting it. Fresh beef or mutton is chopped and put through a sieve, and 200 gm. of tepid water containing 5 gm. of hydrochloric acid are poured over it. In a few minutes 2 gm. of pepsin are stirred into the mixture and the whole is cooked at 38 C. for five to six hours. The product is a reddish fluid with a slightly acid and bitter taste, which can be corrected by adding a pinch of sodium bicarbonate.

Raw-Meat Muscle Serum. Ch. Richet.—The juice derived from meat submitted to a pressure of 25 kilograms to the square centimeter, cured dogs with experimental tuberculosis, in Richet's tests, as mentioned in The Journal at the time. He calls this fluid "myoserum," and states that the curative effect is evident only when as much is injected as 20 c.c. to the kilogram of body weight. He now announces that this myoserum, injected subcutaneously or into a vein, has marked toxic properties, killing animals when employed in the proportion of 5 c.c. to the kilogram. The juice commences to putrify in an hour or two in warm weather and, even when kept at the freezing-point, spoils in a few days.

Berliner Klin. Wochenschrift, January 14 and 21.

Modern Treatment of Diphtheria. T. Escherich.—In this review of what has been accomplished by antidiphtheria serum, Escherich gives his own experience, showing that while 54.8 per cent. of his patients with diphtheria—115 in all—between 1890 and 1894 were cured, since then 86.92 per cent. of 1147 patients have recovered. This includes 80.42 per cent. of recoveries in 378 cases of progressive croup and 57.38 per cent. in 176 cases of septic-toxic variety. None of the latter was cured before 1894, in his experience. He gives 1000 to 1500 units in localized diphtheria, double this amount in progressive croup, and three or more times this amount in the septic-toxic form, but as much as 20,000 units have been given by some physicians. The serum exanthemata have been reduced from 11 to 3 per cent. of the cases. He has had one fatality similar to the sudden death of Langerhans' child, that attracted so much attention a few years ago. A boy of 11 months was given a prophylactic injection on account of sudden laryngitis with symptoms of stenosis requiring intubation. He died in a few hours, with symptoms of heart failure. The heart was found very much dilated and the thymus soft and juicy, weighing 15 gm.

Succussion Sign of Kidney Affections. S. Goldflam.—Pain is a constant and unfailing sign of surgical affections of the kidneys, according to Goldflam's experience, but it is not always easy to elicit the pain. Ballottement is instructive, but even this fails at times. If the patient sits or stands, the trunk bent forward, and the physician strikes the lumbar region with the ulnar side of his fist, lightly but abruptly, perpendicular or lateral to the mass of the sacrolumbar muscles, a concussion of the region is produced which is painless in normal conditions and in certain kidney affections, but in surgical renal affections it induces pain similar to that caused by bimanual palpation or ballottement. No pain is induced by the succussion when the lesion is located in the gall-bladder, spleen or in any organ except the kidney.

Centralblatt f. Bakteriologie (Jena), December 8, 24 and 28.

Theory of Disinfection of the Hands. H. Marx.—The Journal mentioned at the time, Marx's announcement that the accumulation and localization of the Babes-Ernst corpuscles in bacteria is a visible standard for their virulence and vitality. He now announces that the aim of disinfection of the hands should be to render them a destructive soil for microbes, not necessarily to remove all the germs, but merely to prevent their further development. The standard for these conditions is the presence or absence of the Babes-Ernst corpuscles, and this should be the gauge for disinfection of the hands.

Requisites for Formalin Disinfection. C. Spengler.—Tubercle bacilli in sputa are not killed by formalin disinfection as usually performed. Spengler's experience at Davos has shown him that complete destruction of the bacilli is certain if the room is kept at 25 C. during the disinfection, and if the infected substances are moistened thoroughly and give off moisture under the influence of the fumes. The formalin must contain .5 to 1 per cent. formic acid.

December 24.

Microbes in Venous Thrombosis. M. Jakowski.—Venous thrombosis has been noted after typhoid fever, croupous pneumonia, puerperal affections and general septic pyemia. Two cases have been published consecutive to gonorrhea, and Korzon has recently reported a case of pyemia in the course of crural thrombosis during pregnancy. Jakowski has been experimenting on animals, injecting diphtheria or typhoid bacilli and toxins and then applying a ligature to the limb. The toxins alone or combined with constriction failed to induce thrombosis, and the tests were constantly negative in case of constriction alone. But injection of the bacilli and constriction resulted in the production of more or less thrombosis in every case. The bacteria probably lodged at some slight lesion in the vessel, possibly where the constriction was applied, and there elaborated their toxins. These toxins in turn acted destructively on the morphologic elements of the blood, breaking them up and liberating the fibrin ferment, thus causing the formation of a clot.

December 28.

Polymorphism of Water Vibriones. J. H. F. Kohlbrugge.—This author has succeeded in isolating from water several varieties of vibriones which resemble the vibrio of cholera in every respect and possess, in addition, the property of changing their shape. In water they are vibriones; on agar they become rods and cocci and resume the vibrio shape when replaced in water. The lively movements in each phase show that the changes are not degenerative processes.

Centralblatt f. Chirurgie (Leipsic), January 19.

Sterilization of Silk Catheters. M. W. Hermann.—The solution of ammonium sulphate, which Elsberg recommends for the sterilization of catgut (See The Journal, xxxiv, p. 1587), has proved a remarkably simple and effective method of sterilizing silk catheters without the slightest injury.

Centralblatt f. Gyn. (Leipsic), December 22 and January 12.

Gangrene of the Lower Extremity in the Puerperium. G. Burckhard.—Two cases are described which, with those collected by Wormser, raise the number on record to seventeen. In one of Burckhard's cases, the circulation in the leg was impeded from extravasation of blood owing to rupture of the uterus. All the patients recovered after amputation of the leg, except one, and two succumbed without surgical intervention.

January 12.

Injection of Paraffin for Surgical Prothesis. J. Pfannenstiel.—Gersuny's success in treating a case of incontinence of urine by the injection of paraffin was mentioned in The Journal, January 19, p. 219. Pfannenstiel followed his example in a similar case and reports that the results were almost disastrous; the paraffin produced embolism in the lungs and possibly also in the brain, without effect on the incontinence.

Deutsche Med. Wochenschrift (Leipsic), January 31.

Woody Phlegmon. R. Muehsam.—This author describes a case of the rare lesion termed ligneous phlegmon of the neck, by Reclus in 1896. It appeared suddenly during convalescence from broncho-pneumonia, in a robust man of 35, accompanied by slight temperature, and was persistently rebellious to treatment for four months, then gradually subsided, the fistula finally closing three months later. No bacteria could be detected in it, nor evidences of actinomycosis. In other cases various bacilli and cocci and actinomyces have been discovered, and the possibility of the latter infection indicates potassium iodid in dubious cases. One of Reclus's patients died from asphyxia by compression.

Heterogenesis of Lactic Acid Bacilli. A. P. Fokker.—In this preliminary communication, the professor of hygiene at Groningen announces that lactic acid fungi can be cultivated in incompletely sterilized or Pasteurized milk, which can originate only by heterogenesis from the casein. More colonies can be derived from sour milk than according to the microscope, are possible. When the sour milk is filtered in the oven, the filtrate contains more bacilli than when filtered at room temperature. In the latter case a vicarious albuminoid substance is found in the milk in the place of the absent micro-organisms. This albuminoid substance is closely related to casein, and when heated in an alkaline fluid, forms granules. The micro-organisms develop the second day in the incubator before fission of the bacilli occurs, unless the casein is removed, in which case none develops. The phenomenon of heterogenesis can best be observed in incompletely sterilized or fresh milk. Secondary colonies sometimes develop in the midst of the primary colonies, consisting of other varieties of fungi. True lactic acid bacilli cease to develop at a temperature of 60 C., but the lactic acid fungi described above continue to develop in Pasteurized milk. They frequently differ from the familiar lactic acid bacilli in certain respects.

Mastitis Adolescentium. R. Adler.—Besides the case described in this communication, there are only three cases on record in which histologic examination was made. In each of these the gland was normal in structure, and the affection is therefore not an inflammation but a physiologic and possibly atavistic hypertrophy of the mammary gland. The left breast was removed in a youth of 16 years, on account of swelling and pain for several months. There was no secretion. A few months later the patient returned with the other breast in the same condition. Suppuration does not occur in these cases except from secondary infection, the hyperemia offering a *locus minoris resistentiæ*. Adler recommends a celluloid shield to protect the region, fastened with plaster unless extirpation is necessary, abstaining from local remedies.

Wiener Klin. Rundschau, January 20 and 27.

Atypical Initial Symptoms of Tubercular Meningitis. J. Zappert.—Wherever the meningeal exudation makes its way out, the adjoining portion of the cerebrum will show most marked alterations at the autopsy, and possibly also encephalitic destruction. The fresher the exudation and the irritation of the pia mater, the less pronounced the lesion. The anatomist is able, from the postmortem findings, to reconstruct the clinical picture. In case of primary lesion of the total convexity, convulsions must open the syndrome. Aphasia must follow much involvement of Broca's speech convolution, and disturbances in the arm and face must result from a lesion in the cortical centers for the facialis and arm. The muscles of the face on the opposite side and in the further course of the affection, the upper extremity, the leg and, when the lesion is on the left side, the speech, are affected in turn. The cortical localization is clearly indicated by paralysis or cramps in one arm, and also when the symptoms include the face or limb of the same side. Zappert shows, by a number of examples, the actual occurrence of these phenomena as the early symptoms of tubercular meningitis. Cortical centers whose localization is less definitely established than the motor centers may predominate in the clinical picture, as, for example, when the motor disturbances are accompanied or preceded by sensory phenomena. He has had occasion to observe disturbances of the eye muscles and vision due to a lesion in their respective centers, hemianopsia accompanied by unilateral convulsions, in the incipient stages of tubercular meningitis. The primary commencement of the affection in the spinal membranes has also been clinically and anatomically demonstrated.

January 27.

Spray for Rinsing the Bladder. O. Kraus.—The tenacious secretions in certain forms of cystitis, etc., are very difficult to remove from the bladder, and the crevices still contain mucus after the most careful cleansing. This is obviated by the instrument devised by Kraus, which rinses the organ with spray under a pressure of 2½ atmospheres. Carlsbad water is efficient for the purpose, the force being supplied by liquid carbonic acid.

Wiener Klin. Wochenschrift, January 17 and 24.

Relations Between the Nose and the Female Genital Organs. A. Schiff.—By cocainization of the four genital spots in the nose Schiff succeeded in curing 34 out of 47 women of dysmenorrhea. Mechanical and hysterical dysmenorrhea were not affected, but all the cases of nervous origin, with or without palpable lesions in the genital sphere, and also the extramenstrual sacral and abdominal pains were cured. The facts observed indicate that the pain in many cases of dysmenorrhea and similar conditions is not actually genital but originates in menstrual or other irritation of the genital points in the nose, and is projected thence into the sacral and abdominal regions. This cocainization should always be done as a differentiating measure in cases of dysmenorrhea in which the pain does not cease with the commencement of the flow, in order to distinguish between the purely genital and the projected pains. In case of a positive result, the genital points should be cauterized or, better still, treated with bipolar electrolysis. The points must be determined through the speculum and thoroughly anesthetized, preferably with a 20 per cent. solution of cocain. He found it possible in a number of women to cause severe pains in the sacral or abdominal region by excitation of the genital points in the nose, thus corroborating the close connection between them. Weil has observed pain appear in the sacral region in men on tamponning the nose, and has cured forty cases of dysmenorrhea by cocainizing the genital spots in the nose, the influence of suggestion being completely excluded. Gomperz has had a similar experience, but found that the pains were never arrested for more than a year, after which they again required intervention. Grosmann has also temporarily cured epilepsy in a man of 45, arresting the seizures for five weeks by galvanocauterization of the inferior turbinated bone, but they recurred later. He has also succeeded in curing neuralgia of the first and second branches of the trigeminus and three cases of acute lumbago in men by treating the nose. In his experiments on animals, excitation of the superior laryngeal or of the first and second branches of the trigeminus nerve, augmented the blood pressure in the left auricle, with dyspnea. This corroborates the connection which has long been noted between asthma and affections of the nose.

Treatment of Typhoid Fever with Jez's Antityphoid Extract. V. Jez.—In the *Wiener Med. Wochenschrift* of Feb. 23, 1899, Jez first described his extract and reported 18 cases of typhoid fever treated with it. The experience of the last two years has completely confirmed his previous findings, and Eichhorst has also recently reported successful administration of it in 12 cases. The latter remarks: "The rapid improvement in the general condition was astonishing. I applied it only in extremely severe cases, and none of them died. In one case, defervescence occurred in seven days, and in the remainder, in four or five days after commencement of the treatment." The extract has no effect on any disease except typhoid fever. It is entirely harmless and can be administered in large doses, with no after-effects. It diminishes the temperature and strengthens the pulse, abbreviates the course of the disease, and diminishes or completely neutralizes the action of the typhoid toxins. It is administered by the mouth and consequently avoids all the inconveniences of subcutaneous injection. The Berne Serum Institute has undertaken its manufacture, which is not a secret process. Rabbits are immunized against the typhoid bacillus and killed the second or third day thereafter. The extract is derived from the organs, spleen, marrow, brain, medulla, spinal cord and thymus, in which the antitoxin is formed as has been demonstrated on man and animals. The extract is a limpid, reddish, alkaline fluid. A tablespoonful is given every one or two hours, and three tablespoonfuls a day after the morning temperature is reduced to 38 c., a total of 400 to 500 gm. in all. The fever shows the effect of the extract in twenty-four hours, and within forty-eight hours changes from continuous to intermittent and, finally, to apyrexia by the end of the second week. This effect on the fever is so constant that 100 gm. of the extract will prove a valuable differentiating measure. The sensorium becomes clear in twenty-four hours, and the patient is conscious, tranquil, and *free from pain of any kind, demonstrating that the effects of* the typhoid toxins have been neutralized by the antitoxins in the extract. These results, observed in fifty cases, impel Jez to recommend his extract in the most favorable terms. He appends detailed accounts of a typical case treated with it.

Klinitchesky Journal (Moscow), December.

The Eliminating Organs in Typhoid Fever. D. V. Nikitin.—The intoxication in typhoid fever is made up of the acute toxemia from the typhoid toxin, the chronic endogenous and exogenous toxemia which had previously existed in the patient, and the toxemia from disturbances in metabolism during the disease. The liver and skin are most active in the elimination of these toxins, but all the excreting organs in the body assist in the task more or less, and may substitute each other. *The diarrhea in typhoid fever can not be explained* exclusively by anatomic lesions in the intestines, but evidently plays a part in the elimination of the toxins. The vomiting also serves the same purpose. Intestinal hemorrhage in the beginning of the disease can not be considered as the consequence of a lesion, but rather as the result of the hyperemia of the intestines, and it serves to eliminate the toxins in the same way as lavage of the blood is applied in acute uremia. The rapid breathing may also be explained as increased functioning of the lungs—augmented ventilation to eliminate the volatile toxic products and increase the absorption of oxygen. The more intense the toxemia, the harder the eliminating organs work. When the latter are not equal to the task, from congenital or acquired weakness or degeneration of the organism, the disease is liable to terminate fatally. The duration of the disease in many cases is determined by the functional capacity of the eliminating organs. The course of typhoid fever, therefore, according to Nikitin's conception, does not depend on the virulence and other properties of the typhoid bacilli, but on the individual properties of the affected organism and on its equipment for the struggle for existence.

Vratch (St. Petersburg), December 29 and January 5.

Importance of Lowered Sensibility in the Causation of Infectious Diseases. A. K. Federolff.—Scientists have been unable to explain why the chemical products of the vital activity of pathogenic microbes in some cases attract, and in others repel the white corpuscles. Federolff believes that this varying chemotaxis is due to the physiologic condition of the phagocytes rather than to any special properties of the bacterial products. He attributes sensibility and psychic functions to the phagocytes, displayed in their purposeful movements, in their selection of food materials and in their aggressive seizure of the causal agents of infection. If they are benumbed or diseased, then the products elaborated by the bacteria or resulting from their dissolution, fail to incite the phagocytes to their normal aggressive activity. Tests of the effect of narcotic substances on the white corpuscles have demonstrated that their tactile and chemical sensibility are diminished by an anesthetic, exactly as the general sensibility is depressed and the reflexes are abolished by anesthesia. When, from any cause, the products of metabolism accumulate in the blood and lymph spaces; they probably exert a narcotizing influence on the cells and especially on the sensitive phagocytes. As the latter become benumbed and remain passive under this action, their physiologic faculty of producing the alexins—which some claim are bactericidal substances poured out into the blood plasma—is also reduced in proportion. The bacterial products may irritate the blood-producing organs, and so induce leucocytosis, but this is no criterion of the power of the organism to resist infection. The resistance depends on the physiologic condition of the leucocytes rather than on their numbers. In short, Federolff believes that depression from any cause may lead to accumulation of the products of metabolism. These in turn are liable to narcotize the cells—especially the phagocytes—check their functioning, assimilating, oxidations, etc. This allows the germs of infection to develop and elaborate their toxins, unhindered, entailing in consequence some infectious disease.

Queries and Minor Notes.

SECRETARIES OF EXAMINING BOARDS.

Jamestown, Tenn., Feb. 4, 1901.

To the Editor:—Please give the address of the secretaries of the State Board of Medical Examiners of California and Missouri.

M. H. L.

Ans.—The secretary of the State Board of Health of Missouri, by which licenses are issued, is L. C. McElwee, M.D., 1113 N. Grand Ave., St. Louis, Mo. The secretary of the California State Board of Examiners is Charles C. Wadsworth, M.D., 1104 Van Ness Ave., San Francisco.

PRACTICE IN CALIFORNIA.

Socorro, N. M., Feb. 2, 1901.

To the Editor:—Kindly give the requirements of the State Board of Health of California regulating the practice of medicine in that *state, also the name and address of the secretary of the* State Board of Health.

J. F. S.

Ans.—A diploma with affidavit, etc., from a recognized medical college, and a recommendation from some physician in good standing with the State Board of Medical Examiners are required. The secretary, whose address is given in the answer to the foregoing query, will furnish the needed application blanks on request.

PRACTICE IN OREGON AND WASHINGTON.

Lebanon, Kan., Feb. 1, 1901.

To the Editor:—Will you inform me as to the qualifications for the practice of medicine in Oregon and Washington? If an examination is required before a state board, please give their address.

W. C. B.

Ans.—The laws of Oregon and Washington are almost identical. In each state an examination is required and the candidate must, in his application, give full data as to studies, previous practice, etc., by affidavit. Fuller information, application blanks, etc., can be obtained from Byron E. Miller, M.D., Portland, Ore., or W. G. Tucker, M.D., Port Townsend, Wash., secretaries to their respective state boards of examiners.

PRACTICE IN ILLINOIS.

Pittsburg, Pa., Feb. 12, 1901.

To the Editor:—Would you kindly let me know through The Journal the requirements for practicing medicine and surgery in Illinois?

Subscriber.

Ans.—Application for license must be made in writing to the secretary of the board, Dr. J. A. Egan, Springfield, accompanied with proofs of good moral character and of graduation from a recognized medical college, and an examination must be taken. The examination fee of $10 must also be sent. If the application is satisfactory, the applicant will be notified when and where the examination will be held, and, on passing this, will receive his certificate.

EXEMPTION FROM EXAMINATIONS.

Greebville, S. C., Feb. 11, 1901.

To the Editor:—Would a medical college, a private institution, whose faculty are members of the state medical association, under whose appointment their state medical examining board was made, be considered reputable when they, by a majority vote, urged the legislature of their state to exempt their graduates from an examination by said board?

L. C. S.

Ans.—The action mentioned by our correspondent may be reputable enough from a purely *commercial point* of view, though we can not say that it would be in a professional sense. It is certainly against the best interests of the profession and of higher medical education. The Journal has already expressed its opinion in regard to this case and other similar ones. It was not, however, understood at that time that the faculty was advocating the exemption of their students from examinations. To the outside world it looks like a confession of inferiority on their part; that they are afraid to have their students take the examinations. The only other excuse it could have is that they wish to give additional inducements to attend their institution.

WORK ON PROSTITUTION.

Springfield, Ohio, Feb. 9, 1901.

To the Editor:—Can you suggest a work on prostitution, or any source of information in regard to whatever experiments have been made or are being made looking to its restriction or control.

W. B. P.

Ans.—The leading works on the subject are those of Acton and Sanger, the latter the most recent. The subject is a sociologic more than a medical one; the efforts for its restriction are constantly being made; those for its legal regulation or control have not been entirely successful. The matter has been discussed at length, over and over again, and was made the subject of discussion at one of the international congresses held last year, when considerable diversity of opinion was elicited.

New Patents.

Patents of interest to physicians, January 22 and 29:

666,375. Truss. Wm. R. Butler, Richmond, Va.
666,533. Purifying water. Jules H. Lavollay and G. E. Bourgoin, Paris, France.
666,534. Refining perfumes. Jules H. Lavollay and G. E. Bourgoin, Paris, France.
666,431. Electrotherapeutic apparatus. John S. Mead, Buffalo, N. Y.
666,627. Making picric acid. Max Neumann, Wittenberg, Germany.
666,636. Decomposing glycerids. Jonas W. Aylesworth, East Orange, N. J.
666,731. *Electromedical eyeglasses. Philibert Balme, Izieux,* France.
666,844. Sterilizing device. Frank C. Burgholz, Harrison, N. J.
667,144. Static electric machine. Charles H. Cook, Indianapolis, Ind.
667,127. Apparatus for feeding coagulants to liquids. Anthony Harris, Hunters Quay, Scotland.
666,676. Spirometer. Israel Hogeland, Chicago, Ill.
667,099. Treating and utilizing chlorin gas. Edward C. Paramore, Philadelphia, Pa.
667,100. Apparatus for treating chlorin gas. Edward C. Paramore, Philadelphia, Pa.
666,856. Retinoscope. Elmer L. Ryer, New York, N. Y.
666,703. Apparatus for congealing gelatin substances. Christoph Steilacher, Stuttgart, Germany.
33,998. Design, dispensing cabinet. Horace G. Stripe, New York, N. Y.

Copies of above patents may be obtained for 10 cents each by addressing John A. Saul, Solicitor of Patents, Fendall Building, Washington, D. C.

Change of Address.

W. A. Attaway, Nashville, Tenn., to 358 W. 36th St., New York City.
A. A. Ames, 54 3rd St., South, to City Hall, Minneapolis, Minn.
J. J. Ahern, 3851 State St., Chicago, Ill., to Cresco, Ia.
T. B. Busbee, Memphis, Tenn., to Goldthwaite, Tex.
J. W. Bethea, Des Moines, Ia., to Fernwood, Miss.
C. L. Bacon, 410 W. Main St., to 220½ Walnut St., Muncie, Ind.
O. E. Beebe, 227 Hermitage Ave, to 235 Ogden Ave., Chicago, Ill.
Marion Burke, 621 N. Cascade Ave., Colorado Springs, Colo., to 969 San Pasqual St., Pasadena, Cal.
C. S. Burns, Harrison, Ark., to Davis, I. T.
A. Caspe, 253 E. Broadway to 42 Rivington St., New York City.
Chas. Chapin, 1100 Tracy St., to 805 E. 14th St., Kansas City, Mo.
E. L. Clough, Oakdale, La., to Lake Charles, La.
J. J. Cavanaugh, Garland, Kan., to Arcadia, Kan.
J. R. Culbertson, Gray Court, S. C., to Washington, Ga.
C. Cushing, 1607 I St., Washington, D. C., to 696 Sutter St., San Francisco, Cal.
T. E. Chapman, Coats, Ark., to Wirth, Ark.
Geo. S. Darby, 653 to 651 Monroe St., Chicago, Ill.
A. T. Finch, Boydton, Va., to Chase City, Va.
A. T. Fisher, 2120 Vine St., to 2038 Cherry St., Philadelphia, Pa.
H. H. Fisher, Oil City, Pa., to 625 Kelly Ave., Wilkinsburg, Pa.
T. D. Farrer, 3001 to 3020 Lawton Ave., St. Louis, Mo.
M. W. Glasson, 701 S. Cherry St., to 632 S. College St., Nashville, Tenn.
L. C. Grady, 1100 Tracy Ave., to 805 E. 14th St., Kansas City, Mo.
T. A. Grace, Kansas City, Mo., to Orrick, Mo.
J. T. Greenwood, St. Louis, Mo., to Lone Star, Tex.
R. Graham, Seaton, Ill., to Biggsville, Ill.
J. H. Holbrook, Sulphur Bluff, Tex., to Mt. Vernon, Tex.
S. B. Hall, 913½ S. 13th St., to 1616 S. 10th St., Omaha, Neb.
O. F. Howe, Kansas City, Mo., to Medical College, Memphis, Tenn.
A. A. Heinemann, 94 Goethe St., to 56 Goethe St., Chicago, Ill.
G. T. Hunter, Hotel Granada, to 952 Bush St., San Francisco, Cal.
H. E. Jones, Hotel Racine, to 211 6th St., Racine, Wis.
W. B. Kern, Woodriver, Neb., to Hastings, Neb.
Adolfo Luria, 291 Division St., to 291 W. Division St., Station F, Chicago, Ill.
D. McCall, Memphis, Tenn., to Spotville, Ark.
T. A. McNicholl, 1919 7th St., to 221 W. 132d St., New York City.
Minda McLintock, Glenwood, Ia., to 2400 Dearborn St., Chicago, Ill.
J. J. Meany, 2107 W. Madison St., to 1770 Chicago Ave., Chicago, Ill.
J. G. McKinney, Quincy, Ill., to Barry, Ill.
H. S. Nelson, 54 3d St., South, to 1043 Andrus Building, Minneapolis, Minn.
H. H. Procter, Meharry Med. College, Nashville, Tenn., to Auburn, Ky.
E. H. Pomeroy, Calumet, Mich., to Oakwood, Lake Geneva, Wis.
D. J. Prather, 1165 Washington St., Oakland, Cal., to Bakersfield, Cal.
F. B. Romero, Las Vegas, N. M., to El Paso, Tex.
W. G. Rowe, 1834 E. 11th St., Kansas City, Mo., to Grain Valley, Mo.
L. L. Seaman, Hospital Ship *Maine*, Asiatic waters, to 18 W. 31st St., New York City.
Gustavus A. Sulzer, 4 Damarin Block, to 98 E. 2d St., Portsmouth, Ohio.
F. D. Stricker, 616 Elmwood Ave., to Grace Hospital, Detroit, Mich.
A. J. Sanders, Leeds, Ala., to Henry Ellen, Ala.
F. Tice, Omro, Wis., to 1044 W. Monroe St., Chicago, Ill.
J. P. Truax, Fort Casey, Wash., to Fort Flagler, Wash.
J. E. Trexler, Altman Building, to Commerce Building, Kansas City, Mo.
S. M. Taff, City Hospital, St. Louis, Mo., to Fayetteville, Ark.
C. C. Violett, Napoleon, Ky., to Lindsborg, Kan.
W. S. Wolfe, 3230 to 3301 Vista Ave., St. Louis, Mo.
H. Williamson, 270 Woodward Ave., to 52 Forest Ave., Detroit, Mich.
C. Wetherbee, 706 Woodward Ave., to 327 Brush St., Detroit, Mich.
L. G. Witherspoon, 909 W. North Ave., to 1002 W. Madison St., Chicago, Ill..

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Jan. 31 to Feb. 6, 1901, inclusive:

William Alden, acting asst.-surgeon, from the General Hospital, Presidio of San Francisco, Cal., to duty with troops en route to Manila, P. I., and for subsequent assignment in the Division of the Philippines.

Guy G. Bailey, acting asst.-surgeon, leave of absence from the Department of California extended.

William P. Banta, acting asst.-surgeon, relieved from further duty in the Division of the Philippines and assigned to duty in the General Hospital, Presidio of San Francisco, Cal.

Henry D. Belt, acting asst.-surgeon, assigned to temporary duty at Fort Trumbull, Conn.

James Carroll, acting asst.-surgeon, from Columbia Barracks, Cuba, to Washington, D. C., for duty in the pathological laboratory of the Army Medical Museum.

William D. Crosby, captain and asst.-surgeon, U. S. A., member of a board in New York City to examine officers of the Corps of Engineers, for promotion.

Matthew A. DeLaney, acting asst.-surgeon, from the National Soldiers' Home, Va., to temporary duty at Fort Monroe, Va.

J. Ryan Devereux, acting asst.-surgeon, member of a promotion board at Washington, D. C., vice *Captain E. L. Munson*, asst.-surgeon, U. S. A., relieved.

Calvin De Witt, lieut.-col., deputy surgeon-general, U. S. A., leave of absence granted on account of sickness.

Joseph B. Girard, major and surgeon, U. S. A., leave of absence granted.

Albert Hartsuff, col., asst.-surgeon-general, U. S. A., retired from active *service, Feb. 4, 1901, by operation of law.*

Willis S. Horne, acting asst.-surgeon, from Marlin, Tex., to duty at San Antonio, Tex.

Henry S. Kilbourne, major and surgeon, U. S. A., member of a board in New York City, N. Y., to examine officers of the Corps of Engineers for promotion.

F. M. McCallum, acting asst.-surgeon, from Jefferson Barracks, *Mo., to Fort Reno, O. T.*, and return, on temporary duty.

James C. Merrill, major and surgeon. U. S. A., member of a board at the Army Medical Museum, Washington, D. C., to examine medical officers for promotion, temporarily relieving Col. A. A. Woodhull, asst.-surgeon-general, U. S. A.

John W. Ross, surgeon, U. S. N., retired, on duty under the War Department, is assigned to service in the Department of Cuba.

Edward A. Southall, acting asst.-surgeon, from the General Hospital, Presidio of San Francisco, Cal., to duty with troops en route to Manila, P. I., and for subsequent assignment in the Division of the Philippines.

August von Clossman, acting asst.-surgeon, now in St. Louis, Mo., to report for duty as examiner of recruits in that city.

Joseph W. Walsh, acting asst.-surgeon, from Brooklyn, N. Y., to duty at the General Hospital, Washington Barracks, D. C.

Marshall W. Wood, major and surgeon, U. S. A., to take charge of the medical supply depot at St. Louis, Mo., during the temporary absence of Major J. B. Girard, surgeon U. S. A.

In addition to the above, the following named acting asst.-surgeons were directed, Feb. 1, 1901, to proceed from the places set opposite their names to San Francisco, Cal., for duty with troops en route to Manila, P. I., and for subsequent service in the Division of the Philippines: Polk D. Brown, Hartsville, Tenn.; Henry M. Hall, Cedartown, Ga.; Melville A. Hayes, Washington, D. C.; Edgar W. Miller, Chicago, Ill.; Frank W. Pease, Wahpeton, N. D.; Julius M. Purnell, Paris, Ky.; Anton R. Schier, Oconomowoc, Wis.

Boards to Examine Candidates for Admission Into the Medical Corps of the Army.—Special Orders No. 28, of Feb. 2, 1901, Headquarters of the Army, Adjutant-General's Office, Washington, D. C., provide for the organization of two boards on Monday, Feb. 11, 1901, at 10 o'clock a.m., or as soon thereafter as practicable, for the examination of candidates for admission to the Medical Corps of the Army. These boards will be governed in their proceedings by such instructions as may be communicated to them by the Surgeon-General of the Army. One is appointed to meet at the Army Medical Museum Building, Washington, D. C. It will consist of Col. Alfred A. Woodhull, asst.-surgeon-general, U. S. A.; Maj. Louis A. La Garde, surgeon, U. S. A.; Capt. William C. Borden.

asst.-surgeon, U. S. A., and Capt. Frank R. Keefer, asst.-surgeon, U. S. A. The other is directed to meet at the U. S. General Hospital, Presidio of San Francisco, Cal. Its membership consists of Lieut.-Col. Benjamin F. Pope, deputy surgeon-general, U. S. A.; Lieut.-Col. Alfred C. Girard, deputy surgeon-general, U. S. A.; Maj. Robert J. Gibson, surgeon, U. S. A., and Capt. William H. Wilson, asst.-surgeon, U. S. A.

Navy Changes.

Changes in the Medical Corps of the Navy for week ended Feb. 9, 1901:

P. A. Surgeon J. A. Guthrie, detached from the *Franklin* and ordered to the *New York*, February 18.

Surgeon A. M. D. McCormick, detached from the Naval Hospital, Norfolk, Va., and ordered to the Naval Academy, February 2.

P. A. Surgeon R. Spear, detached from the *Buffalo*, on arrival at Cavite, and ordered to the *Isla de Luzon*.

Asst.-Surgeon W. B. Grove, detached from the *Vermont* and ordered to the Naval Hospital, New York.

Asst.-Surgeon W. H. Bucher, detached from the Naval Hospital, New York, and ordered to Naval Hospital, Norfolk, Va.

Asst.-Surgeon M. V. Stone, detached from the *Isla de Luzon* and ordered to the *Buffalo*.

Medical Inspector E. Z. Derr, ordered to the Naval Academy, February 14.

Surgeon W. R. DuBose, detached from the Naval Academy, February 13, and ordered to the *Wisconsin*.

Medical Inspector D. M. Bertolette, ordered to the *New York*, February 16.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ended Feb. 7, 1901:

Surgeon Preston H. Bailhache, relieved from duty as chairman of the board for the physical examination of Second Asst.-Engineer R. F. Halpin, R. C. S., Feb. 4, 1901.

Surgeon G. T. Vaughan, detailed as chairman of the board for the physical examination of Second Asst.-Engineer R. F. Halpin, R. C. S., Feb. 4, 1901.

Asst.-Surgeon G. M. Corput, bureau order of January 26, directing Asst.-Surgeon Corput to proceed to Cleveland, Ohio, for temporary duty, revoked, Feb. 2, 1901.

Asst.-Surgeon Edward Francis, to proceed to Cleveland, Ohio, and assume temporary command of the service during the absence on leave of Surgeon Pettus, Feb. 2, 1901.

Acting Asst.-Surgeon J. C. Ballard, granted leave of absence for five days from February 7, Feb. 4, 1901.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended Feb. 9, 1901:

SMALLPOX—UNITED STATES.

Florida: Jacksonville, Jan. 26-Feb. 2, 1 case.

Illinois: Chicago, Jan. 26-Feb. 2, 4 cases, 1 death.

Kansas: Lawrence, Jan. 26-Feb. 2, 2 cases; Leavenworth, Jan. 1-31, 4 cases; Wichita, Jan. 26-Feb. 2, 22 cases.

Kentucky: Lexington, Jan. 26-Feb. 2, 2 cases.

Louisiana: New Orleans, Jan. 26-Feb. 2, 9 cases, 2 deaths.

Massachusetts: Lawrence, Jan. 26-Feb. 2, 2 cases.

Michigan: Grand Rapids, Jan. 26-Feb. 2, 1 case; Manistee, Jan. 26-Feb. 2, 4 cases.

Montana: Butte, Dec. 26-Jan. 20, 39 cases.

Nebraska: Omaha, Jan. 19-Feb. 2, 6 cases.

New Hampshire: Manchester, Jan. 26-Feb. 2, 32 cases.

New York: New York, Jan. 26-Feb. 2, 50 cases, 2 deaths; Utica, Jan. 19-29, 1 case.

North Dakota: Morton County, Jan. 30, 10 cases.

Ohio: Ashtabula, Jan. 26-Feb. 2, 2 cases; Cleveland, Jan. 26-Feb. 2, 49 cases, 3 deaths.

Pennsylvania: Allegheny City, Jan. 26-Feb. 2, 5 cases; Erie, Jan. 26-Feb. 2, 2 cases; Pittsburg, Jan. 26-Feb. 2, 8 cases.

South Carolina: Greenville, Jan. 26-Feb. 2, 1 death.

Tennessee: Jackson, Jan. 1-31, 20 cases, 2 deaths; Memphis, Jan. 26-Feb. 2, 18 cases; Nashville, Jan. 26-Feb. 2, 4 cases.

Texas: Galveston, Jan. 12-26, 37 cases.

Utah: Ogden, Jan. 1-31, 32 cases; Salt Lake City, Jan. 26-Feb. 2, 29 cases.

Wisconsin: Eau Claire, Jan. 22, 12 cases: Washington Township, Jan. 22, 20 cases; Green Bay, Jan. 26-Feb. 2, 1 case; Milwaukee, Jan. 26-Feb. 2, 2 cases.

SMALLPOX—FOREIGN.

Austria: Prague, Jan. 5-12, 21 cases.

Belgium, Antwerp, Jan. 12-19, 3 cases.

Brazil: Rio de Janeiro, Dec. 1-15, 27 deaths.

England: Bradford, Jan. 23, 4 cases; Newcastle on Tyne, Jan. 12-19, 6 cases.

India: Calcutta, Dec. 15-29, 72 deaths; Karachi, Dec. 16-23, 5 cases.

Japan: Korea, Seoul, Dec. 22, many cases and deaths.

Russia: Moscow, Jan. 5-12, 2 cases, 1 death.

Scotland: Glasgow, Jan. 18-25, 324 cases, 3 deaths.

Spain: Barcelona, Nov. 25-Dec. 30, 71 deaths.

YELLOW FEVER.

Colombia: Cartagena, Jan. 8-13, 3 deaths.

Cuba: Cienfuegos, Feb. 1, 1 case; Havana, Jan. 22-29, 1 death.

CHOLERA.

India: Calcutta, Dec. 15-29, 87 deaths.

Straits Settlements: Singapore, Dec. 8-15, 25 deaths.

PLAGUE—UNITED STATES.

California: San Francisco, Jan. 12-19, 2 cases, 2 deaths.

PLAGUE—FOREIGN.

India: Calcutta, Dec. 15-29, 46 deaths.

Japan: Osaka, Dec. 22-Jan. 7, 3 cases; Wakayama, Dec. 22-Jan. 7, 1 case.

Turkey: Smyrna, Dec. 30-Jan. 6, 1 death.

THE JOURNAL OF THE
AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, $2.50. Subscriptions may commence at any time. Volumes begin with the first issue of January and of July.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The qualifications for membership require that the applicant be a member, in good standing, of a state or local medical society entitled to send delegates to the annual meeting of the American Medical Association. A list of these societies will be sent on request. Applications must be accompanied with a certificate showing that the applicant is a member of a recognized society, and should be sent with the annual dues—five dollars—to the treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago. Members receive The Journal free. Subscribers to The Journal may become members of the Association without additional expense if they are members of medical societies recognized by the Association. Those desiring to have their names transferred from the subscription to the membership lists should send certificates as above, with a receipt for their subscription to The Journal, covering the current fiscal year.

FISCAL YEAR.

The fiscal year of the American Medical Association is from January 1 to December 31; and the annual dues paid by a new member cover only the fiscal year, no matter at what time of year the membership is obtained. Those who pay their dues and join the Association at the annual meeting in June, for instance, pay only for the fiscal year which ends with the December following, and the annual dues for the following fiscal year are payable the succeeding January, at which time the treasurer sends a statement to each member. Such members, however, are entitled to The Journal for the full year, even though the membership be not continued.

PAPERS READ AT THE ANNUAL MEETING.

"Every paper received by this Association and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the Association. . . The Board of Trustees shall have full discretionary power to omit from the published transactions, in part or in whole, any paper that may be referred to it by the Association or either of the Sections, unless specially instructed to the contrary by vote of the Association." (From Article V of the By-laws.)

NEWS.

Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

ORIGINAL PAPERS.

Articles are accepted for publication with the understanding that they are contributed solely to this journal.

COPYRIGHT.

Matter appearing in The Journal of the American Medical Association is covered by copyright, but as a general thing, no objection will be made to the reproduction of anything appearing in its columns if proper credit be given.

CONTRIBUTIONS TYPEWRITTEN.

It will be satisfactory to all concerned if authors will have their contributions typewritten before submitting them for publication. The expense is small to the author—the satisfaction is great to the editor and printer. We can not promise to return unused manuscript.

Half-tones, zinc etchings and other illustrations will be furnished by The Journal when photographs or drawings are supplied by the author.

ADVERTISEMENTS.

Advertising forms go to press eight days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. Advertising rates will be made known on request.

CHANGE OF ADDRESS.

In ordering a change of address it is important that both the old and new addresses be given.

REMITTANCES.

Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "Journal American Medical Association," except those for annual dues. These should be made payable and sent direct to the Treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago.

The Journal of the
American Medical Association

Vol. XXXVI. CHICAGO, ILLINOIS, MARCH 2, 1901. No. 9.

Address.

NUTRITION AND STIMULATION.*

I. N. LOVE, M.D.
NEW YORK CITY.

"There has been a wave of enthusiasm affecting the profession for the past three decades, which has been growing stronger each year, and is now truly at its flood, and this wave has concerned itself chiefly with what has been termed scientific research. We are all now ready to announce our belief that the laboratory side of medical science must be cultivated as a foundation for the whole superstructure of more or less empirical clinical facts, and we have given evidence by the establishment of numerous institutions for study along these lines, and more will follow. More systematic and accurate methods are being applied throughout the entire field of medical practice than ever before, and every worker, whether wielding the microscope, manipulating cultures or making clinical observations and studying bedside symptoms, realizes the importance of thoroughness and the application of careful scientific methods."[1]

In passing it may be well to suggest that the term "scientific" has been used in too narrow a sense by many members of our guild. A recent writer very tersely says: "The use of the word 'scientific' in a narrow sense as applied to laboratory work, has done much to arouse prejudice and establish false standards. By degrees there has grown up a distinction, which is now heard on every hand, between what is termed 'scientific medicine' and 'practical medicine' naturally with the implication that practical medicine as personified in the practitioner is not scientific. In other words 'scientific' as popularly used in medical writing and discourse, demands a laboratory and the accessories which a laboratory implies, whereas the man who is examining his patients from day to day in most painstaking and accurate fashion is looked upon as a faithful and conscientious practitioner, but not as a scientific investigator. So deeply has the laboratory impressed itself upon the uncritical thought of the time, that he who often aimlessly looks through a microscope, or with narrow vision describes a lesion, is placed upon a pedestal as a man of 'scientific' tendencies, while his colleague who faithfully describes a symptom is denied any such distinction."

"The reason for this anomalous state of affairs is certainly not far to seek. It lies in the fact that accuracy and hence knowledge have, in great measure, come by way of the laboratory. The insistence on the necessity of exact observation and description has certainly not had its origin with any one set of investigators in the general field of medicine. The laboratory worker deals with problems of the most complex sort, and on the other hand with facts which may be easily and accurately described. His claim to distinction as a scientific man does not, however, lie in his description of isolated facts, but wholly upon his attitude toward the problems, the solution of which depends upon the proper interpretation of those facts. Certainly nothing is simpler than to go into a laboratory and to describe at any length what one sees under a microscope. This is, however, not science, however often the results may masquerade as such, nor does the mere accomplishment of such work constitute a scientific man. But to go into a laboratory, to study facts laboriously, and then to appreciate clearly the meaning of those facts for the sum total of knowledge and to make generalizations therefrom is, properly speaking, 'scientific.'"

Says the same writer: "We are safe in saying that all which is concerned with the acquisition of accurate and systematic knowledge of principles, by observation and deduction, is scientific. We must realize that a cell, as seen under a microscope, is no more an object of scientific investigation than a cough and a chill." Indeed, we must be imbued with the thought that the science of the sickroom, the science of life, its continuance, the securement of growth, the science of nutrition by which growth is accomplished, the securement and maintenance of a strong, robust, healthful physical and mental makeup and a useful, graceful old age, are all quite as important and worthy of our religious regard as laboratory results and deadhouse details.

Continuance of life, commencing with the original protoplasm, the cell, depends upon proper nourishment and a proper recognition of this fact, and attention to the means of securing this result is the duty of the physician. In other words, the physician should be interested in the child, from, and even before its conception.

May we not hope that the time will soon come when the physician will be the family counselor, and not alone be called to see individual members of the family when sick, but consulted prior to any important domestic movement, especially in advance of all matrimonial plans.

A reckless disregard of the physical equipment of either one or both parties in a matrimonial partnership can only result sorrowfully: "A child born weakly—of weakly parents, maybe—perhaps weds precociously a weakly wife or husband, 'produces weakly children, and they weaklier children,' of whom it may be emphatically said, 'better they had not been born,' 'for life is not to live, but to be well.' Without being actually ill, however, they are ever ailing, never healthy, never strong, sturdy, and active, as are many others; appetite is capricious, seldom good; food not taken with relish, hunger a sensation unknown to them; the poor, puny, pining things may be said to vegetate from day to day, instead of thrive and enjoy life; the pleasures of childhood are not theirs. 'A hale cobbler is a better man than an ailing king,' tersely and truly wrote somebody, 'for life consisteth not in the abundance that a man possesseth,' and compared with a good constitution, all the wealth of the world is nothing; yet how marvelously little do some, in their thirst for riches or position, 'appear to think this when sanctioning or encouraging ill-assorted or non-assorted marriages, regardless of physical and mental fitness, and that common sense should tell them can only result in disaster.' Were parents careful as to the companionships their children form, instead of anxious for them to ally with those of every wealthy *roue*, who bear about them the too manifest constitutional deterioration it is desirable to avoid, we should be less often shocked by the pitiable objects we sometimes encounter."

---

* Address in Medicine to the Mississippi Valley Medical Association, Asheville, N. C., October, 1900.

1. Boston Medical and Surgical Journal.

2. Ibid.

If the physician could have a voice in the decision of these matrimonial schemes it would be well, but whether he has or not, he surely should be constantly on duty after marriage as the adviser and helper in the securement of a healthful and well-endowed heir.

We should insist, except in rare instances, that married life is a failure unless a child be born within a year, and we should encourage the thought that barrenness is acknowledgement of physical or moral delinquency, and in nearly every case is a reflection on the party of the second part as well as the party of the first.

Let us insist, that the future man will be a more complete and perfect specimen if we as physicians can be permitted to feed him or direct his feeding from the moment that he is conceived and starts on his life's career. Every mother or prospective mother should be taught that she is, from the time she reaches puberty, built and equipped for two, for herself and the child that from the beginning it was intended that she should bear and rear. And so, when bearing her child, the mother should be taught every detail of personal hygiene, proper feeding and elimination not only for her own sake, but for the health, life and perfection of the coming child.

Dr. Arthur W. Johnstone recently presented a most valuable paper, with the title "Auto-intoxication from Defective Menstruation," from the standpoint of nutrition, on the utility of the function of menstruation as providing a means of elimination for the surplus unused in child-bearing, demonstrating that many nervous symptoms of gynecologic subjects were due to retained excretions from defective menstruation, explaining many points of the pathologic features of puberty and the menopause.

The chief definite knowledge of proper infant feeding on the part of the medical profession has been the development of the past twenty years. There was no real check on the "slaughter of the innocents," the fearful, the awful infant mortality that obtained the world over until the problem of infant feeding was properly solved, and the first step in its solution was the appreciation of the fact that the substitute food for the babe must be sterilized, and the second was to know that sterilization means cleanliness rather than the destroying of micro-organisms in the food at the expense of killing the vital elements therein by cooking them to death; the third step was the recognition of the fact that infantile intestinal disturbances were almost uniformly caused by improper food and relief depended on the correction of the food-supply and the accomplishment of proper intestinal drainage—the removal from the bowels of the irritative materials. The pioneer work of Pasteur, Tyndall, Lister, and others was quite as important from a medical and dietetic standpoint as from the surgical one.

It is needless for me to draw attention to the essential elements of proper food. We are all familiar with the three general groups of elements or necessary food, which may be subdivided into: 1, the mineral—water, salt, ashes of plants and animals; 2, the carbonaceous or respiratory—heat-giving, starch, sugar, fat, etc.; 3, the nitrogenous—flesh-forming, tissue-building, such as albumin, fibrin, casein, etc. It stands to reason that throughout life the mineral and respiratory foods are necessary in full amount, but that when the individual has gained full maturity, complete growth, say after the age of 30, the nitrogenous or tissue-building foods are demanded in smaller quantity, and after 40, the middle mile-post of life, has been reached, less than one-half or even one-third as much animal food is required as during the period of development. This is not sufficiently appreciated, and the continued use of large quantities of nitrogenous food after maturity accounts for numerous diseases.

The investigations and views of Haig, Garrod and others are being daily confirmed by careful observers as to the close relation existing between the excessive use of animal food and gouty as well as organic diseases in general. Close study of numerous victims of the gouty diathesis, hereditary and acquired, has convinced most observers that the proper solution of the problems involved lies along the lines of judicious diet, which involves especially the reduction of animal food consumption and a more liberal use of fruits and vegetables. When we realize how close the relation is between gouty conditions, atheromatous degeneration, tuberculosis, cancer, general organic disease, premature age, and animal food in general, we will surely study the question most assiduously.

The liberal eating of fruit is a most excellent habit to form; it not only opposes constipation and favors the freest elimination in a general way, but the mineral salts contained in the fruit largely affect favorably the elimination of uric acid. The free eating of cherries, strawberries and grapes is an excellent fruit cure, and Weiss, acting on the recommendation of Woehler and Linnaeus, has recently made experiments which determine that quinic acid is probably the active ingredient present which acts as a curative agent in gouty states. A decoction of the root and leaves of the strawberry plant has long been a favorite domestic remedy in gout in some parts of Russia.

As a proper selection of the full varieties of food, and their complete digestion and proper assimilation, together with perfect elimination—in brief, a perfect scheme of metabolism—are essential to growth, so they are demanded after full growth is accomplished, in maintaining a healthful condition of the animal mechanism; but, as previously stated, the essentials for keeping up the equilibrium of metabolism in the latter period are different.

The scheme of metabolism includes assimilation or tissue-building, the power which the animal organism possesses of accumulating from its food supplies a store of potential energy, which is able to transform into kinetic energy and which commonly manifests itself in the form of muscular work and the production of heat, and finally the formation and elimination of excretory products which result from the changes which occur in the constituents of the tissues as the necessary accompaniments of such transformation of energy.

The balancing of the bodily income and expenditures is the essence of health. The real effect of food is to repair waste, administer to the growth of the bodily organs, maintain the balance of nutritive and temperature equilibrium under the varying conditions and circumstances to which the individual may be exposed, to maintain all the animal functions in complete activity and prevent loss of weight.

It is well that we exercise our intelligence in the selection of foods essential to health, to the proper running of our mechanisms, and remember that we eat to live and must not simply live to eat. In other words, after maturity there is grave danger to us in the cultivation of epicurean tastes, the love of the tickling of our palates.

It is not always safe to trust merely to the sensations of hunger, surely not to capricious choice or fanciful desires. We can not too strongly emphasize the thought that high livers are short livers. It is the part of wisdow for us all, then, to realize that as we approach maturity we must be satisfied to eat less and eliminate more, and that the greatest helper in the flushing of the eliminating organs is large quantities of pure water. Bodily exercise is absolutely essential to healthful activity of the eliminating organs, and unless we wish to be full, dull, heavy, luggy, and lazy as well as fair and fat at forty, we must keep moving and echo loudly the words of wisdom, "Blessed be drudgery." As an exercise walking will ever continue to be healthful and good. We as physicians fail in our duty when we do not announce in strongest terms not only the advantage from the standpoint of happiness, but also of longevity, of plain living and high thinking.

During this last decade we have added more definitely to our knowledge of the keystone in the arch of metabolism, the glandular system, than ever before, and during this period we have secured our first real knowledge of those glandular organs which had previously been considered as almost superfluous, the ductless glands, such as the thyroid and thymus. It would be most interesting to review the bearing of these glands on growth and health, both mental and physical, but time will not permit.

As we have studied food problems, we have had crowded on us more and more every day the necessity of state legislation in the matter of pure food laws. Correspondence with many thousand physicians during the past year elicited almost uniformly the view that legislation which will favor purity of food laws can not be too strict. Members of the medical profession of Missouri, almost to a man, have endorsed the legislation which precludes the sale of baking powders containing alum, an astringent which is certainly not favorable to good digestion, and other more comprehensive laws should follow. An investigation of the whole field of food adulteration presents facts which are almost appalling.

Some writers have placed under the head of medical or auxiliary foods those things which go to make up stimulants, neurotics and narcotics, such as alcohol, tea, coffee, tobacco, etc., but the expression, "auxiliary food," is of doubtful propriety. The term should surely be applied only to those things which are necessary to life.

ALCOHOL.

Among the so-called auxiliary foods alcohol is the only one which is open for discussion. Accepting as we may the views of Dujardin, Thompson, Pavy, Burney Yeo, Atwater and others in favor of the fact that when alcohol is ingested in the system in moderate quantities a part is utilized and only a part eliminated and it is therefore a food, it does not follow that it is essential to life. Many things may be oxidized and used in the body, and be a food to that degree, yet not be a desirable one. The evidence is constantly accumulating that, as a food, alcohol is of doubtful utility, and the list of valuable foods that are in no way involved in doubt, and certainly not harmful and dangerous to the body, mind and soul, is so great that alcohol as a food may well be left out of our nutritive philosophy and be permitted to take its place as a stimulant pure and simple. As a matter of fact, the dangers that are associated with alcohol are so great that it should only be classed under the head of medicines and luxuries. As a luxury, it certainly adds to the sum of human conviviality, cheerfulness and happiness when used in very moderate quantities, but then only with the meal. If used liberally it takes its place along with opium and Indian hemp, primarily as an exhilarant and secondarily a depressant and narcotic. A very limited amount of alcohol with the meal now and then does, to advantage, stimulate appetite and improve digestion, and by its psychic effect, making the user enjoy his food and environment, it may be helpful. The limited amount of good that it may do, in this way, in a few rare cases, is offset a thousand, yes, a million, fold by the awful dangers which accompany its use. The writer has for years had liberal views on this question, and while he believes that the proper solution of the temperance question lies in teaching every child from the beginning until matured to be the ruler of its own spirit, to cultivate self-denial, self-control, self-respect, yet more and more as time passes he believes that absolute avoidance of alcohol in all its forms as a beverage, as a luxury, is the safest course for all, and that while now and then a strong, self-reliant, rigid back-boned individual may with impunity take his occasional drink or liberal indulgence, the endorsement given to the drinking of alcohol by his act and the injury to his brother, whose keeper he surely is, however much he might wish to avoid his responsibility, is an unanswerable argument against him.

No one better than a physician knows the awful results to humanity, physical, mental and moral, of alcoholic indulgence. So that while being gently tolerant of the views of those not agreeing with me, I am strong in the conviction, after many years of study of the subject, viewed from the standpoint of experience and observation, that as a luxury alcohol should be ruled out of our lives.

While holding this view I but regret that many opponents of alcohol are so severe, intemperate and almost unkind in their discussion of the question. Is it not better for us all to make our appeal in a kindlier spirit of charity, to the judgment and intelligence of all concerned, presenting the argument that alcoholic indulgence is an injury to ourselves—a weakness, its excessive indulgence a vice, not a crime?

Alcohol as a medicine, a prompt and diffusible stimulant, has great value, but as each half decade of my experience has passed and I have taken stock of my knowledge I have been stronger in the view that in the majority of cases it can be dispensed with. In advanced stages of typhoid fever, pneumonia, tuberculosis and sepsis it certainly meets conditions admirably, and yet in many of these we can substitute hot milk, coffee, tea, strychnia, normal salt solution and other remedies to advantage.

Alcohol has been more abused, more excessively and needlessly used, more misapplied, than any other one remedy. The London *Lancet* recently quoted from the *New York Medical Journal* for Aug. 19, 1900, a case reported by Dr. M. A. Walker, of a boy of 6 years, who, before breakfast, about 8:30, drank 3 ounces of whisky. The parents knew nothing of this until about 9:30, when the boy, while sitting at the breakfast table, dropped a plate and then fell from his chair. At 10:15 he fell asleep on the floor, and his mother put him to bed thinking he would "sleep it off." There was no thought of serious consequences until 7:30 p.m., when the parents could not arouse him. At 7:45 he was comatose, the pupils were widely dilated and did not respond to light. The pulse was 145, small, weak, and compressible; the respirations were 40, easy, and quiet. The axillary temperature was 103.2 degrees. In spite of treatment—which was not described—circulation and respiration slowly failed. At 10:30 severe clonic convulsions occurred and lasted about ten minutes, and from this time there were almost constantly recurring localized spasms of the face and extremities, the left side being much more affected than the right. Cheyne-Stokes respiration began about 2:45 a.m., and death from cardiac failure occurred at 5 a.m. No means of stimulation seemed to have the slightest effect on the heart. The rectal temperature rose to 105.3 degrees just before death.

What physician who closely scans the details in this case does not recall the victims of typhoid fever, pneumonia and diphtheria, in the years gone by, who were similarly symptomed from alcoholic drenching? Let me urge one and all in the coming years to have a care in the administration of alcohol—it is as dangerous as a drug, as it is as a food.

Duty demands that physicians utter a note of warning against the use of alcohol in any form by women. Drinking on their part, whatever it may be abroad, is on the increase in America, particularly among the wealthy, the leisure class. The modern woman is not as busy in a domestic way as she once was. In many of the leading cities of America the free drinking of wine by very respectable women in public places is too common, and some of them now liberally indulge in the luxury of the cocktail and high-ball, and overwhelming evidence can be presented that the soda fountain is a popular rendezvous for fashionable female tipplers in some of our leading cities. This is an awful thing. It is bad enough for men to drink, but for women it is physical, mental and moral suicide. Their emotional make-up is such as to render the drinking of alcohol in any form deadly dangerous. At this point it can not be too strongly stated that a physician should only in the direst extremity administer alcohol to a woman; to a nursing mother, never. Too often beer, or some sloppy substitute masquerading in its place is given to the nursing mother to increase her flow of milk. It should never be done.

TEA, COFFEE, ETC.

Coffee, tea, cocoa and chocolate are all popular aromatic beverages which, while differing considerably from one another in their common physical characteristics, all agree in containing alkaloids closely resembling each other. Coffee and tea contain the active principles caffein and thein, practically identical, and the others contain an alkaloid of theobromin, which is very like them. Coffee is the more powerful and, on account of having much less tannin than tea, is not so constipating. Tea, being less potent, is a safer beverage if used liberally. Chocolate, as prepared from the cocoa of commerce, is very weak in the alkaloid theobromin; being very rich in cocoa-butter, made with milk as it usually is, it makes a most nutritious drink.

Coffee properly made is a great comforter to mankind, if not used to excess. It is truly "the cup that cheers but does not inebriate." It is a decided stimulant to the nervous system. Used intelligently it is a great conservator of energy, lessening the need for sleep after exertion, and removing the "tired feeling," and the best authorities claim that it has the power of augmenting the functional activity of the muscles, and a very stimulating effect on the heart, in small quantities quickening its action, in large quantities slowing it, while in excess it seriously disturbs its rhythm and regularity. If the digestion is above par, tea and coffee may be taken with meals, but if impaired they should be taken pure, without cream or sugar, an hour or two before meals. Coffee increases the secretion of the skin and the kidneys, and in the majority of cases it increases the flow of bile, peristalsis, and thus antagonizes constipation. This is more apt to be the result if it be taken as a pure infusion an hour or two before meals, on an empty stomach.

Tea and coffee, being stimulants, should not be given to children, on the principle that thoroughbred, spirited colts need no whip, but oats instead. Unquestionably the milder stimulants given to children during the growing period favor the appetite for stronger ones later.

It is well to remember that one good strong cup of coffee twice a day is ample for the average adult, and if taken in this way, if any exceptional demands be made on one's strength or endurance the additional cup of coffee will assist in meeting the emergency admirably. In the sick room, or for the victim of surgical shock, a good strong infusion of coffee by the mouth or the rectum, is in the majority of cases superior to alcohol.

TOBACCO.

Tobacco is a luxury which may very properly be classed, save in its dangerous features, with coffee and tea, but, like them both, it increases the power of resistance of the individual to fatigue and enables him to meet great tests of endurance and indulgence in prolonged abstinence from food. Tobacco differs from alcohol in every essential; the latter, whether we accept the idea that it is a food or not a food, can only be pronounced poisonous or dangerous so far as the individual dose is concerned when given in very large quantity, whereas tobacco in itself contains—no matter how small a portion—an active poison, a narcotic, which readily affects the brain. The secondary effects of *all* stimulants like alcohol and sedatives like tea and coffee are narcotic, but some, like tobacco, opium, henbane, etc., seem to immediately attack the centers of the brain.

The tobacco plant belongs to the genus Nicotiana, a name given to it in honor of Jean Nicot, a French ambassador at the court of Portugal, who first introduced this plant into France. Belonging to this genus are several species which yield at the present day the tobacco of commerce. These plants belong to the natural order Solanaceæ, a family which yields us not only tobacco but stramonium (Jamestown weed), belladonna (or deadly nightshade), henbane, cayenne pepper, tomatoes, ground cherries, potatoes and mandrakes.

A well-known writer has observed: "At first sight this looks like an incongruous family, but still there are certain common properties running through the whole order. All contain, more or less, substances that act on the nervous system, and thus increase from the mild poisons of the solanums till we arrive at the deadly principles of the atropas, the henbanes and the tobaccos. It seems well established that smoking was introduced from the new into the old world, yet in the latter there was ample material for its indulgence, for at least two species of Nicotiana, the N. rustica and N. persica, are indigenous to Asia. The American plant, the Nicotiana tabacum, has been one of the most cultivated, and Virginia, Kentucky, Maryland and Ohio are the states where it has been raised to the best advantage. Canada has produced some fairly good tobacco, South America sends its tobacco to Europe in large quantities, but for a long time the best in the world has come from Cuba. Our new possession, Manila, has furnished a high-grade specimen of great fame. From Persia has been brought the refined and delicate 'Shiraz tobacco' procured from Nicotiana persica, but the most aristocratic variety, Latakia, is produced in Turkey by the Nicotiana rustica. In Africa and Egypt the American species thrive. Algeria furnishes the chief supply of tobacco to France, and this explains the zeal of custom house officers at French ports in promptly confiscating the personal supply of cigars in the belongings of American globe-trotters. Germany, Holland and other European countries furnish a proportion of low-grade specimens.

Tobacco is used in three different ways, either chewed, smoked or in the form of snuff through the nasal passages. It would be interesting to discuss the details of the manufacture of tobacco, its proper treatment before being ready for chewing, smoking or snuffing, but in each case the effect is the same and the result depends on the absorption of the active principle, nicotin, and whether one snuffs, chews or smokes, unless he be possessed of a strong will power, he becomes more and more a slave to a narcotic but a step removed from those which are more alluring, such as opium, morphin and cocain.

In order to fully understand the effect of tobacco it is well to understand its constituent parts. In the analysis of a pound of tobacco, the fresh dried leaves, we have:

	Ounces.	Grains.
Nicotin	0	419
Concrete volatile oil	0	7
Chlorophyl	1	46
Gum	1	222
Starch	0	279
Albumin and gluten	0	349
Sugar	0	139
Salts	2	245
Water	1	402

In chewing tobacco about the only constituents which can exercise much influence on the system are the nicotin and volatile oil. The soluble salts would act the same as the saline constituents of the other plants and they explain why tobacco is such an exhausting crop for the soil. Among the salts of tobacco the nitrates are the most abundant, and this explains the ready way in which tobacco burns in the process of smoking. In snuffing, the soluble parts of the tobacco, as in chewing, are, after being dissolved, absorbed through the mucous membrane. In these latter days we understand that the intense vascularity of the nasal mucous membrane permits rapid absorption and the nicotin readily enters the circulation, the same as we have demonstrated that solutions of morphin do, and as thoughtless rhinologists have shown, in their temporizing and palliative treatment of nasal catarrh and hay-fever by means of the cocain spray.

In considering the chewing of tobacco from a medical standpoint we have to consider the nicotin absorbed through the buccal and pharyngeal mucous membranes and the small amount probably swallowed, together with the draught on the salivary glands and the waste of saliva. The chewing, viewed from a polite standpoint, unless absolutely in private, can not be considered other than in bad form. In the animal economy we have the secretory and excretory system of glands; the product of the former are essential to the proper performance of physiologic duty within the body and must be husbanded, and the latter are no longer needed and naturally seek the external world, but their proper disposal should be in private, away from the haunts of men, surely not in a way to offend the feelings of others or to make of one's self a public nuisance. So tobacco-spitting can not be excused under any circumstances from the polite standpoint, but the saliva is a secretion, not an excretion, and its free expectoration is a needless waste.

The use of tobacco by smoking is becoming more and more the almost exclusive way, and while in the earlier days the pipe was much in evidence, the cigar has almost crowded it out. It is interesting to study the history and preparation of tobacco and the manner of making cigars, but the main thing for us to recall is that while a good cigar, used very temperately two or three times a day, may be smoked by the average adult man to good advantage, excessive indulgence in smoking is very harmful. It is only necessary to recall one's first cigar and the profound effect it produced, to realize that the smoking of tobacco in large quantities is trifling with a dangerous agent.

In tobacco smoke we have the following: nicotin, empyreumatic oil, butyric acid, carbonic acid, ammonia, paraffin, empyreumatic resin, acetic acid, carbonic oxid, carburetted hydrogen and water.

The chief effects of smoking are from the nicotin and empyreumatic oil, the first being an active poison —an infinitesimal quantity will destroy life—and the latter, which is the rank accumulation in the stem of the pipe, is also a potent poison, one drop on the tongue of a cat having been fatal. The nicotin and the oil both act on the nervous system, though differently, the nicotin paralyzing the heart by its action on the brain, while the oil confines itself chiefly to the spinal cord and the motor nerves. It will thus be seen that no part of the victim's equipment escapes the deadly effect of tobacco in excess; as Lankester observes, "the nicotin seizes on the main citadel and the distilled oil attacks the outposts, and the whole man—body and mind—is brought under their influence."

1. Smoking in excess is more harmful than chewing, for the reason that the nervous system is not only more injuriously affected, but the catarrhal disturbances of the air-passages render the smoker more liable to dangerous and fatal diseases of the air-passages.

2. The excessive smoker is not only more liable to pneumonia, la grippe, tuberculosis, laryngeal and pulmonary, as the sensitive mucous surface and the bankrupted nervous system present a double invitation at all times, but fatal results are more apt to occur. Every case of laryngeal tuberculosis coming under my observation for several years has presented a history of the victim being a smoker, in the majority of instances to excess.

3. Heart failure is a frequent complication and serious with excessive smokers.

4. Cigarette smoking is worse than either the cigar or the pipe, but only for the reason that, the cigarettes being milder tobacco, the smoker almost universally inhales the tobacco fumes, and when we realize the component parts of tobacco smoke and how direct the routes from the air vesicles of the lungs into the blood current we can appreciate the ill effect.

5. Inveighing against the cigarette on the ground that the paper is poisonous and the tobacco drugged, mixed with opium, Indian hemp, etc., is all wrong, as the cigarette being a milder tobacco, perfectly pure, and the paper unobjectionable, if smoked without inhaling and in a temperate way, is to be preferred.

6. The cigarette smoker nearly always inhales the smoke and, becoming habituated to this quick toxic action, he will not smoke without inhaling whether he uses the cigarette, the cigar or the pipe, for the same reason that the morphin habitue accustomed to the hypodermic method will not be satisfied with the drug through the mouth; both victims want quick action.

7. Children who use tobacco before reaching maturity have their growth interrupted, as nothing more definitely interferes with the equilibrium of the tissue-building, digestion, assimilation, elimination, metabolism, than tobacco, and for these reasons its use favors gouty diseases, atheromatous degeneration, premature senility and decay. The excessive users of tobacco are crippled in their general equipment and are in no form to wrestle successfully with any disease.

8. He who smokes cigarettes to excess, or uses tobacco in any form to excess, is in danger of becoming an alcoholic, but in even greater danger of becoming a drugger, as tobacco is so closely allied to opium and Indian hemp. In a general way one excess invites another, as the will power becomes lessened.

9. Nothing is so apt to bankrupt the sexual equipment as tobacco, unless it be opium, as it stands to reason that a cerebrospinal paralyzant must obtund sexual desire and power.

10. The numerous mental wrecks, youths who have come under my care during the past ten years, whose lives were failures, or who fill suicides' graves, impress me that to-day tobacco stands as the gravest danger confronting the new century, and the medical profession has a fearful responsibility in educating young men and their parents to appreciate this danger.

The business world is, I am glad to see, undertaking the solution of the tobacco problem the same as it has that of alcohol, in that it is declining to employ cigarette fiends as well as moderate or excessive drinkers.

I am firm in the view that the medical profession must study calmly, tolerantly, temperately, the problems related to stimulants of all kinds, but tobacco and alcohol in particular, and they put themselves in best form for doing the best work along these lines and wielding their greatest influence for good, by themselves being exemplars of temperance, self-restraint, self-denial and correct living.

49 West Forty-fourth Street.

Zinc Oxid in Putty.—The French minister of public works has prohibited the use of white lead and ordered zinc oxid to be used in its place in putty, etc. This is the result of the efforts of Dr. Laborde, who has emphasized the injury from lead poisoning from this source, and proved that harmless zinc oxid is an efficient substitute for it in most of the various uses to which it is applied.

THE RESULTS OF THE SURGICAL TREATMENT OF INFLAMMATION OF THE MASTOID PROCESS.*

EDWARD BRADFORD DENCH, M.D.

Professor of Otology, University and Bellevue Hospital Medical College; Aural Surgeon to the New York Eye and Ear Infirmary; Consulting Otologist to St. Luke's Hospital; Consulting Otologist to the New York Orthopædic Dispensary and Hospital.

NEW YORK CITY.

The subject upon which I wish to speak has been so thoroughly considered during the past few years, it would be manifestly impossible for me to give more than my own personal experience in regard to it. What I wish particularly to emphasize, however, is the advisability of early operation in doubtful cases, and to show by my own statistics that the procedure itself is practically free from danger.

At the present time the general surgeon does not hesitate to open the abdominal cavity for diagnostic purposes. In the same way, I believe the otologist is perfectly justified in exploring the mastoid cells, whenever there is the slightest evidence of an inflammatory process. In the vast majority of cases, the signs are so well marked that a diagnosis can be easily made. In some, however, especially in those patients in whom the pneumatic cells of the mastoid are well developed, it is impossible to make an absolutely positive diagnosis until the disease has existed for several weeks, and sometimes for several months. When these cases are operated upon, the destruction which has taken place is invariably found to be extensive, and recovery is necessarily slow. Had operative interference been instituted when the first signs of the affection appeared—in other words, had an exploratory operation been done, the patient would have been relieved at a much earlier period, and a long and tedious convalescence would have been avoided.

So far as the operation itself goes, I am convinced that it is absolutely free from danger, if conducted in an aseptic manner. By this, I mean that the field of operation, the hands of the surgeon, the instruments employed, the sponges, ligatures, dressings, and, in fact, everything which is introduced into the wound, must be thoroughly aseptic. As much care must be taken in the preparation for such an operation as if the surgeon intended to enter the cranial cavity. The operator can never tell the extent of the disease in any given case, and not infrequently finds that there is an extension to the cranial cavity, in cases which have appeared comparatively simple.

The technique of the operation is too well known to require any description. I have only a few suggestions to make in regard to the method of operating. In the first place, the incision through the soft parts should be made as close to the ear as possible. If this is done, there will be no deformity after the operation; secondly, in every instance, I believe it wise to explore the entire pneumatic structure of the mastoid process, including the cells at the apex of the process. We often find the pneumatic spaces filled with granulation tissue or with pus, even when they are covered by a wall of apparently healthy bone. This is especially true of the cells at the tip of the mastoid. Another point is that, in every instance, the mastoid antrum should be entered, as a first step of the procedure. Even in cases where the cortex has been perforated spontaneously, I do not think it wise to begin the operation at this point. The mastoid antrum should always be entered in the usual manner. If this is done, the accidental exposure either of the meninges or of the lateral sinus will occur less frequently, while, at the same time, perfectly free drainage from the middle ear will be obtained.

---

* Presented in a Symposium before the Section on Laryngology and Otology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Regarding the practice of closing a portion of the superficial wound with sutures, in order to render the recovery more rapid, my own experience has been that this procedure is scarcely advisable. Recovery is quite as rapid if the entire wound is treated by the open method, and any danger of pus retention is also completely avoided.

In 273 cases operated on, in not a single instance could death be attributed to the operation. Cases suffering from intracranial complications prior to the mastoid affection, are naturally excluded from this list. The simple point, however, which I wish to make is that the operation in itself is perfectly safe, and is a warrantable procedure as a diagnostic measure in doubtful cases.

TREATMENT OF CHRONIC OTORRHEA.[*]

FRANK ALLPORT, M.D.

Professor of Ophthalmology and Otology, Northwestern University, Woman's Medical School; Professor of Ophthalmology, Chicago Polyclinic; Oculist and Aurist to St. Luke's, St. Joseph's and Wesley Hospitals.

CHICAGO.

The subject of chronic tympanic suppuration is an important topic of aural surgery. The purpose of this paper, however, is not to introduce novel procedures for its relief, but rather to summarize our knowledge and endeavor to ascertain the crystallized sentiment of otological experience. For, be it remembered, unanimity by no means exists concerning relief measures for this troublesome and dangerous pathological condition, its treatment ranging all the way from the time-honored syringe to the radical mastoid operation. If concrete opinions concerning curative measures prevailed, no excuse would exist for this paper, but the discrepant views entertained by eminent authorities on both sides of the Atlantic furnish ample provocation for an endeavor to produce order from apparently chaotic conditions.

A professional classification according to expressed views might be designated as follows: The ultraconservatives, conservatives and radicals. 1. The ultraconservatives are those still possessing an abiding faith in the syringe, cleanliness, insufflations, drugs, mild surgical procedures such as polypus removals, etc., and who believe that all decided surgical measures, such as ossiculectomies and tympanal curettage, or worse, are not only unnecessary, but unwarrantably dangerous unless distinct mastoid symptoms are present. 2. The conservatives are those who give the previous treatment an opportunity of several months to effect a cure, failing in which, the tympanum is usually swept clear of pathological products. Many of them, but not all, regard a radical mastoid operation as a dernier ressort, not to be performed until all other means have failed, after persistent effort, and perhaps not then in the absence of mastoid symptoms. Other conservatives advise a radical operation more readily. 3. The radicals are those who waste no time over the preceding methods, but open the antrum, mastoid and tympanum as soon as chronicity is established. In this view they are supported by the opinion that the mastoid antrum is an actual anatomical extension of the tympanic attic and usually participates in chronic suppuration of the latter, and should be thoroughly opened and cleaned as soon as brief ordinary unavailing treatment has practically proved the existence of antral disease. They believe, therefore, that chronic otorrhea implies antrum involvement, perhaps induced by exuberant middle-ear granulations, which retain antral pus, unreachable and incurable by tympanal treatment or operation, and that such measures are mere placebos. They feel that necrosed bone in other parts of the body, even when exposed to view and readily subject to local treatment by acids in proper strengths, is treated by the skilful surgeon by radical surgical intervention, and not by tedious and unsatisfactory applications. They feel that the important and complicated structures of the middle ear should be treated upon the same general surgical principles, but with their importance much accentuated. They also believe that an effort should be made to save the ossicles in a fairly physiological condition, naturally impossible after ossiculectomy, and that the only probable method of accomplishing this is by the performance of the radical operation.

Among the ultraconservatives, according to their writings, may be classed Ole Bull, Manning, Dentovitch, and the late Samuel Sexton. Among the conservatives may be classed Shepherd, Black, Stucky, Buck, Gomperz, Burnett, Randall, Reinhard, Politzer, McBride, Lucae, Guye, Gradenigo, Eemann, Barr, Faraci, Buller, Cheatle, and White. Besides these Noyes is inclined to conservative views, while leaning somewhat toward ultraconservtism, with great faith in the "dry treatment" of chronic otorrhea. Dench and Vulpius, while still believing in a fair trial of conservative measures, are more and more impressed with the necessity for radical procedures, which they perform much more frequently and unhesitatingly than formerly. Dench shows a record of 64 per cent. of cures by the radical operation, as against 58 per cent. by ossiculectomy. Knapp expresses the same views, and believes that during the last few years the indications for intratympanic operations have steadily lost ground. He does very few of them, but has not utterly abandoned them. He thinks the indications for the radical operation are always strengthened in the presence of such constitutional diseases as tuberculosis, diabetes, syphilis, etc. Milligan has not abandoned conservative measures, but believes that twelve months of faithful treatment should be considered sufficient, after which, if the discharge continues, he would perform the radical operation. Among the radicals we find such names as Stacke, Schwartze, Macewen, Siebenmann, Jansen, Holmes, Alderton, Lane, and Gleason.

One noticeable feature of these lists is the evidence of surgical evolution and progress for, while such lists are, of course, numerically quite incomplete, their proportions and characters are unquestionably a fair representation of professional opinion. The time is fast disappearing when capable and conscientious surgeons are contented to indefinitely and dreamily subject such patients to interminable treatment, with the assurance that conditions are improving, and that a cure may some day be anticipated. Nor must this pessimism be construed into a lack of reasonable faith in ultraconservative measures. Much may be accomplished by antiseptic syringing, especially if effected by a good intratympanic syringe. Benefit unquestionably frequently follows what is known as the "dry treatment," peroxid of hydrogen, acids, iodin, enzymol, powder insufflations, gauze-drainage—which serves to keep the meatus sterile, cuts off the entrance of staphylococcus, and drains and asepticizes tympanal exudations—inflation, alcohol, granulation removals, and the numerous other suggestions for pursuing this plan of treatment. Procedures of this kind are undoubtedly frequently followed by satisfactory results, both as to discharge and hearing, but it is more than questionable whether it is justifiable to positively or negatively assume that our weapons for battle are thus limited, and whether patients should be permitted to continue the possessors of a disgusting and dangerous condition, owing to professional and mental inertia or a fatuitous faith in the direct therapeutical interposition of Divine Providence.

---

[*] Presented in a Symposium before the Section on Laryngology and Otology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Some ultraconservatives reluctantly admit that the time may come, in the treatment of a case, when the boldness of an ossiculectomy may be indicated, but that momentous event is delayed to the very last moment of several years, hoping that at last persistent and varied efforts will finally be crowned with success. They believe that in the narrow confines of the tympanic cavity there is much room for mishaps and that an ossiculectomy being performed out of sight, and with great dependence upon the tactile sense, is fraught with much possible danger, and cite instances where the facial nerve, jugular vein and carotid artery have been injured and infection has developed along venous or other channels to the intracranial contents, with fatal results, especially where a granulation plug occludes a communicating opening between the brain and tympanum, forgetting apparently the lamentable end of many patients who have with their lives testified to the inefficiency of this line of treatment, persistently employed. The mere question of thoroughly cleansing an ear is by no means a simple one in chronic otorrhea. It is frequently surprising how mass after mass of foul material can be forced away by painstaking use of an ordinary syringe, supplemented by a tympanic syringe, peroxid of hydrogen, alcohol and inflation, and much time may be consumed before an ear may be considered even moderately clean. It will thus be seen how irksome these procedures must become to a busy surgeon, when daily repeated, especially when occurring in dispensary practice.

Concerning the use of the more or less popular "dry treatment," it is difficult to understand how even ordinary cleanliness can be obtained without the use of an intratympanic syringe, especially when used with peroxid of hydrogen, etc. The attic, where the trouble is usually most pronounced, is a complicated structure, containing the ossicles and many folds and sacs, well qualified to retain mucus, pus, desquamations, etc., difficult or impossible to dislodge by a cotton-tipped probe. If not dislodged, these foul products must remain the focus of disease. While, therefore, fully aware of the unfortunate effect of moisture in these cases, the writer is of the opinion that of the two evils, the lesser is the one which makes an effort at a thorough cleansing of the parts, until all detritus has been removed and all odor—due to saprophytes—has been dissipated. The parts may then be dried painstakingly with cotton, inflation, dry, and possibly hot, air, and the desired treatment applied. The names of those favoring the indefinite pursuance of this method are numerically small, and growing smaller each year.

The conservative ranks are numerically the strongest and contain those surgeons who have graduated from the ultraconservative column, but are not yet ready to say that a radical operation is always indicated in chronic otorrhea. There is considerable diversity of opinion among these surgeons upon several points. For instance, some believe that the patient should be given the benefit of perhaps a year's treatment before any operative procedures are undertaken, which operation should then be an ossiculectomy and curettage, to be followed possibly later by a radical operation, especially if mastoid or head symptoms supervene, if irrigation expels cheesy matter or mother-of-pearl flakes, if the discharge continues fetid in spite of persistent irrigation, if granulations recur when removed or cauterized, and if caries, especially of the posterior attic or meatus, is present. Others again cut down the treatment period to one or two months, to be then followed by the operative procedures just mentioned; while others, who are about ready to swell the radical columns, are willing to treat the case for about one month, when, if discharge continues, an ossiculectomy or possibly a radical operation is advised. In the event of the latter advice the ossicles may also be dealt with as seems best after a thorough post-aural examination. Upon one point there can scarcely be a divided opinion, namely, that the thorough performance of an ossiculectomy and curettage is a long step in advance and places the patient in a much more favorable condition for drainage and treatment than before, even if discharge does not cease, or recurs. The operation is attended with but little annoyance to the patient; tinnitus and vertigo are often much relieved; the thickened and functionless tympanic structures are removed; drainage is much improved; the tympanum can be much more readily reached for treatment; hearing is often benefited—for if ossicular continuity is severed by caries of the malleus and incus, or retarded by pathological middle-ear products, such as exuberant granulations, cholesteatoma, etc., sound waves can not reach the labyrinth even with reasonable ease, and hearing is naturally affected—and all conditions are bettered even if a cure is not effected, which, if we are to believe the statement of many competent observers, is not by any means an event of rare occurrence.

It must also be remembered that even after the patient has been induced to undergo a radical operation we sometimes find during the operation that no especial disease existed in the antrum or cells, and that the operation has hardly been essential, and a regret must be felt by a conscientious surgeon, that more persistence in conservative treatment had not been exercised.[1] This is emphasized by the reflection that even the radical operation is not always followed by a complete cure of the discharge (although some surgeons feel they can assure their patients a safe and sure result), which it appears should somewhat restrain enthusiasm for its universal performance. It should not be forgotten, however, that most serious and deep-seated pathological conditions are sometimes found in the course of a radical operation or at a post-mortem, when subjective and objective symptoms have been of the very slightest character.

The personal equation of surgeons should also be considered in the advisability of the advocacy of the frequent performance of the radical operation. This operation is by no means a simple one. There is probably no space of equal size in the body surrounded by so many dangerous elements as the space involved in the tympano-mastoid procedure. It is hazardous ground for the novice or for him who is not thoroughly grounded in the topography and surgical anatomy and abnormalities of the parts. Again, all operators are not equally skilful, and an operation that might be reasonably safe in the hands of a Stacke or a Macewen, might be exceedingly dangerous when performed by some other aurist, who, while inexperienced, might be unwilling to admit it, and who might feel that he must follow in the steps of the master, even if his services are supplemented by those of the undertaker. It certainly requires conviction and courage to advise a radical operation in the absence of mastoid symptoms, especially in the early stages of a chronic discharge. So many people are unquestionably cured of such a discharge without an operation that patients who become familiar with this fact must indeed have supreme faith in their surgical adviser when they mount the operating-table under these circumstances, and it must be admitted that a consequent facial paralysis, impaired hearing, protracted healing, continued discharge, fistula or death, can not serve to exalt the professional position of the operator in the minds of the laity, the profession or even himself. Of course, the complexion of the case absolutely changes in the presence of long-continued discharge unchecked by persistent conservative procedures, cholesteatoma or of mastoid or intracranial symptoms, under which circumstances the patient himself frequently demands radical relief. But in the absence of such indications, no surgeon should be blamed for the advocacy of conservative measures, especially when it is remembered that a cessation of the discharge and improvement of hearing frequently follow ossiculectomy and curettage. These illy defined and insidious forms of chronic otorrhea with antrum or cell infection, but unaccompanied by palpable symptoms of such extensions, are certainly difficult ones in which to decide upon a plan of action unless one happens to be a radical in his opinions. The gravity of the situation may not be always measured by the quantity, quality or odor of the discharge, although these indications often mean much, but certain ill-defined symptoms, such as a slight rise in temperature, irritability, nervous exaltation, mental depression and general appearance of parts, are not without their significance.

Concerning the radical operation, it may be confidently stated that he must be very conservative indeed who denies the advisability of such a step in the presence of mastoid or intracranial symptoms, or of distinct organized cholesteatomatous masses. And there are many eminent surgeons who would not advise a radical operation in long-continued and intractable discharge without the above history, but there are at present comparatively few who are willing to go on record as advising such an operation as soon as chronicity of the discharge is established, say in a few weeks after the inception of the discharge. And yet we must not forget the eminence of authority on this side of the argument, nor fail to lay much stress upon their plainly spoken opinions. Most of the radicals are our teachers, men to whom we look for advanced and correct thought, and their sentiments can not and should not be turned lightly aside and dismissed as too extreme. It may be that their very eminence and skill in operating, however, has much to do with their results and consequent views, and the question may be most justly raised whether inferior but ambitious operators are warranted in following their leadings. Stacke, for instance, believes that ossiculectomy without the radical operation is a mistake, as it destroys ossicular aids to hearing. He advocates the radical operation as soon as the discharge becomes chronic, hoping thereby to save the ossicles and the function of audition. He says the ossicles can be removed later if necessary. Siebenmann, Jansen and Scheibe endorse these views, and the latter claims that in any case of otorrhea, if the odor is not removed by intratympanic syringing, the radical operation should at once be performed. Macewen lays down this axiom: "When a pyogenic lesion exists in the middle ear or in its adnexa, which is either not accessible or which can not be effectually eradicated through the external ear, the mastoid antrum and cells ought to be opened." This statement is in reality not so bold as would at first appear, for most surgeons would concede the advisability of a thorough exposure of the parts were they positively assured of pyogenic extension beyond the tympanic area. But such positive assurance is not always apparent, and in the dimness of an uncertain diagnosis hesitation is natural. It is like appendicitis; if suppuration could be positively located in the appendix no one would fear to operate, but in the absence of such an assurance surgeons frequently wait, fortified by the long list of recoveries without operation. Not many doubt the advantages of a successfully performed radical operation when the parts are thoroughly exposed to view and their complete inspection possible. Investigations may then be pursued in all directions, pathological conditions removed, pyogenic extensions prevented, asepsis secured, and a logical expectation of a cure entertained. Macewen claims that pathological middle-ear products can be removed not only easier, but safer by the mastoid than by the meatus route. He feels that in chronic otorrhea the tympanum is septic, and that operative procedures in this area expose fresh surfaces to pyogenic influences and simply court disaster. Such views are undoubtedly enveloped in much truth, but surely the radical operation itself is not utterly devoid of danger, and a properly performed ossiculectomy is most infrequently followed by a fatal or unfortunate result.

It will thus be seen that there exists considerable apparent diversity of opinions concerning the treatment of chronic otorrhea, and it would appear that much misunderstanding could be averted if conditions rather than a name might be considered. Some surgeons believe that cases of chronic otorrhea do very well under such and such treatment. Others believe that ossiculectomy and curettage are indicated, and still others that a radical operation must be performed. The old Oriental story is recalled of the three blind men who went one day to inspect an elephant. "He is like a spear," said one who *grasped the tusk*. "He is like a fan," said another who felt of his ear, while the third, with his hand on his leg, declared he was like a tree. They had all inspected the elephant, but naturally formed different ideas of his appearance. So it is with chronic otorrhea. Various observers form various views from various experiences, while if all would carefully inspect each case and judge of its treatment on its own individuality it would be seen that there is ample room for all opinions in considering this interesting subject and its treatment. A chronically discharging ear does not always indicate the same pathological conditions. A simple exudative mucous-membrane inflammation may exist, with imperfect drainage, which may be healed by an enlarged opening and simple treatment. Or exuberant granulations may be present, which are removable and curable. Or ossicular or mural caries may occur, relievable by acids, drainage, treatment, etc., or an ossiculectomy and curettage. Or the disease may have extended farther into the antrum, and even here it is not inconceivable that a removal of intratympanic contents, supplemented by good drainage and proper treatment, may effect a cure, although it is admitted that the radical operation will usually be indicated. Or the mastoid antrum and cells may be involved and possibly the sinuses and intracranial contents, calling for prompt and large operative procedures. So instead of assuming that chronic otorrhea must always be treated upon certain clearly cut principles, it would be better to examine each case independently as to its pathological condition, symptoms, duration and character of its discharge, etc., and advise a plan of action harmonious with such unprejudiced examinations and observations.

The dividing pathological line seems to be the extension of the disease to the antrum. Before this occurs tympanic treatment and operations should prove sufficient, although, as has been before stated, Stacke and other eminent authorities believe that when a chronic discharge is established a post-aural operation should unhesitatingly be done, with the hope of preserving the ossicles and good audition. It is scarcely believed, however, that the profession is yet ready to accept these ultraradical views, especially when the danger of the radical operation in all hands is considered, and the very good hearing frequently obtained, even when the tympanum is swept clear of its contents. After the antrum is clearly involved most competent observers will agree as to the indications for post-aural operations, while even here many capable men wait for mastoid and other significant symptoms, although the supporters of this view are steadily growing less.

How then may we determine the existence of antral disease in a case without significant symptoms? It is impossible to answer this question definitely, there being no fixed rules by which to ascertain such extension in quiescent cases, and an opinion must be accumulated by composite observation, which is nevertheless reasonably trustworthy. Aural discharge, especially if persistently foul and profuse, continuing in spite of proper local treatment for a period say of three months, is a decidedly suspicious condition, particularly when accompanied by recurrent and persistent exuberant granulations and necrosis. Especially is this true if the membranal opening has been in Shrapnell's membrane, or in the posterior superior quadrant of the main membrane, and if carious bone can be located in the upper and posterior wall of the tympanic cavity, or if the upper and posterior walls of the deep meatus are red, bulging or sensitive. These observations are much strengthened if the discharge is cheesy or flaky or contains the streptococcus, influenza or tubercle bacilli, and if the tympanum has been cleared by an ossiculectomy and curettage. A case presenting such a picture, or even a reasonable portion of it, even if absolutely unaccompanied by mastoid or other significant symptoms, would certainly lead most progressive surgeons to unhesitatingly advise either an ossiculectomy or a radical operation.

It is impossible to deny that the trend of high professional opinion at the present time turns toward the latter view. Perhaps this is inevitable and proper, but let us not advance too hastily. Let us rather err in the direction of conservatism, feeling that important and complicated operations will be the natural evolution of added knowledge.

92 State St.

Medical students in the German universities this winter show a considerable decrease in numbers. Last year there were 7543 in attendance, but at present only 7113.

BONY DEFECTS AND FISTULÆ IN THE EXTERNAL MEATUS.*

H. GRADLE, M.D.

CHICAGO.

The occurrence of artificial communicating passages between the meatus and attic of the middle ear is, on the whole, little referred to in literature; it is mentioned, but not commented upon, in some of the larger text-books. Some illustrations of it are given in Politzer's "Beleuchtungsbilder des Trommelfells," etc. Yet it is not a rare lesion, as I have seen considerably over 20 instances, and can refer now to some 20 complete records. The last 12 cases were found amongst 2000 ear patients. The defect is usually a fissure of variable size in the external wall of the attic, opening through the upper wall of the meatus above Shrapnell's membrane. In some instances it seemed to be a fistula instead of a complete gap, but it is not always possible to distinguish between two conditions.

Small defects are difficult to recognize by sight and may be found only by the use of the probe. The end in the meatus is often narrower than the opening into the attic, which is in rare instances exposed to partial view. The membrana tympani was totally gone, or nearly so, in a few of the cases. In most of them the tense portion of the drumhead was intact and the perforation limited to Shrapnell's membrane.

Most of the patients were seen on account of the discharge. Several, however, had no secretion at the time of the examination, merely asking help for their hearing. As in all forms of purulent otitis, the hearing in a given case may be very little or very much damaged.

The patients were all adults, who dated their ear-trouble back to childhood. No case was observed from the beginning. The origin of the gap in the bone must, of course, be attributed to caries, but no evidence of its continuance was found in most of my patients.

The existence of a fistula into the attic does not add to the gravity of a chronic case. In consideration that these were all cases of disease of the attic, their course may even be said to have been relatively mild, perhaps on account of better drainage. One time only were distressing symptoms—vertigo and headache—observed during a subacute exacerbation. Of 20 patients, 19 were cured without any operation, some being observed many months, others several years. Even the one patient not cured under treatment claimed to have lost the discharge by treating himself according to directions while on business travels; but this is only hearsay evidence. A cure for the time being was admitted only, if on repeated trials no trace of discharge could be found on exploring with a cotton mop, or on searching for it in the pus basin after syringing the ear. Relapse, however, must be expected in some of these cases, and indeed about one-third of them did return, sometimes repeatedly—after intervals of months or years. The relapses were as easily checked as the previously continuous disease.

A frequent cause of relapse is desquamation of the epidermis, which had grown through the fissure into the attic. Cholesteatomatous contents were found in six patients, often in the form of concretions, which could be picked out in a single mass. This process of desquamation continues after suppuration is arrested. Several patients have returned once in 1 to 3 years, presenting again the concretion in the attic, but without symptoms or odor. In none of the cases was there any reason to suspect that the desquamative process extended beyond the attic.

---

* Presented in a Symposium before the Section on Laryngology and Otology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Relapses occurred also in a few who had no cholesteatoma. Under the head of relapse I do not include recurrence of secretion within a few days after apparent cure. This is quite common, and the observation should not cease until the ear has been dry a few weeks. The reasons for real relapses after months or years of apparent cure are not entirely clear—apart from cholesteatoma. Caries no doubt complicates a large proportion of all cases of attic suppuration, much more often than can be detected by the probe. The occurrence itself of a hole in the bone is proof that there was caries originally, though not necessarily present at the time of examination. But, contrary to views occasionally found in literature, caries does not prevent permanent recovery as long only as the pus is in no way pent up. Both among these patients with bony perforations, as well as among others without this complication, I have on record many permanent cures, in spite of existing caries, confirmed by re-examination after years. As long, however, as the foul odor of the discharge shows interference with free drainage, recovery is out of question. On the other hand, necrosis of bone with the presence of a sequestrum is an absolute barrier to the cessation of the discharge.

The treatment of chronic otitic suppuration is not altered by the existence of bony defects, perhaps even facilitated. The all-important condition is the complete removal of all pent-up discharge, as well as cholesteatomatous masses. Granulations need to be curetted only if they interfere with drainage. An infallible guide for controlling the efficacy of the treatment is the odor of the discharge. A fetid smell shows pus-retention, even if it be only on a microscopic scale. As long as this exists no complete cure is possible, while the removal of the odor is proof positive that the conditions are now favorable for cicatrization. Formerly, after mechanical cleansing by the syringe, a fine intratympanic canula and the curette if needed, I depended mainly on insufflation of boric acid, varied sometimes with instillation of alcohol-ether solutions of iodoform and carbolated glycerin.

After many years of use of this method in chronic otitic suppuration in general, I am still satisfied with its efficacy and promptness, provided it succeeds within a few days at the most in completely conquering the odor. The continuance of this treatment is, however, absolutely useless if the odor does not yield. A potent additional measure was suggested, first, I believe, by N. Pierce, about three years ago. It is capillary drainage by a gauze drain. A peculiarity of this method, which has not been pointed out before, is that it will gradually remove the odor in eight to fifteen days, while lessening the discharge. Intratympanic syringing and the use of the curette followed by boric acid powder either deodorize in a few days or fail altogether. Gauze drainage, on the other hand, may not change the smell until the discharge has nearly stopped. While in the cases now under discussion at least a temporary, and mostly a permanent, cure was obtained by these different methods in all but one doubtful instance, even the drainage method will, of course, fail at times in chronic otitis. When the attic is obstructed by adhesions around the carious ossicles, nothing but ossiculectomy, and when the antrum has carious walls or cholesteatomatous contents nothing but radical operation can cure the disease. The drainage method, however, limits the indication for these surgical measures. Only I am not yet assured regarding the permanency of cure by gauze drainage.

Capillary drainage is effective only if the absorbing material is almost in contact with the secreting focus. I can suggest an improvement on gauze strips, as they often cause pain when pushed in with the probe. For some months I have used strips of sterile blotting paper, about 0.5 millimeter wide and 20 long. They absorb more energetically than any gauze. As additional aseptic precaution I have powdered them freely with boric acid. They can be inserted through the speculum with scarcely any discomfort, and made to touch the drumhead or exposed internal wall of the middle ear. The auricle is then packed with gauze powdered with a mixture of boric and salicylic acids.

DISCUSSION ON PAPERS OF DRS. KNAPP, RICHARDSON, CALHOUN, DENCH, ALLPORT AND GRADLE.*

DR. W. K. SIMPSON—One thing interesting to me was in Dr. Allport's paper, as to what should be done in cases of chronic suppurative disease of the middle ear, as to whether we should treat it or whether we should be radical, and the question arises: why are some men radical? If we will study some of the cases Makuen reports, we will see why he is radical. When we consider some of the cases that come to him that have been left to God Almighty and the syringe, and badly neglected, it is no wonder that Makuen and such men are radical. It is proper for the essayist to dwell upon this matter, but it is a question that we must decide for ourselves. The treatment of intracranial affections recalls to us, who went into the study of medicine about the time appendicitis was discovered, a parallel of that disease. The large number of patients who formerly died of "inflammation of the bowels" we now know died of appendicitis. And so now we know that many who formerly died of "brain fever" died of disease of the middle ear. "Brain fever," like "inflammation of the bowel," covered a multitude of evils. The difficulty of diagnosing intracranial lesions in children has interested me very much. I have accumulated a few cases with the specimens. This one it seems to me is dependent on, in the first place, anatomic elements, and in the next on physiologic elements. The cerebral centers are not thoroughly established, and I am satisfied that if we wait in a child, to make the diagnosis, until we can make one of these feather diagnoses we read about in the text-books, we will not make one in time to save the child's life. The diagnosis in most instances has been made by what we might call main strength and awkwardness. [Laughter.] Perhaps I had better illustrate what I mean. We know that one case does not prove very much, but it takes a good many things in inductive reasoning to prove anything. The case was one of a child 3 years of age, in which the doctor called me and said the child seemed to have typhoid fever, but did not have the typical typhoid temperature. The child had not spoken for two weeks. The pupils showed nothing, physical examination showed nothing, and there was nothing to localize the trouble. But there had been a discharge from the ear for some months. I reasoned that here is a child that probably will die soon if nothing is done. I believed that there was present a suppurative otitis media and the chances were that the temporosphenoidal lobe was involved. I knew that I could not wait, so I operated at once without an anesthetic and the child got well.

DR. O. JOACHIM, New Orleans, La.—I desire to present for inspection a specimen obtained from a patient I operated on. When he came under observation he was delirious, unable to answer any questions and presented all the symptoms of intense pyemia from purulent lateral sinus thrombosis of otitic origin. I operated promptly and found extensive alterations. There were perisinual and epidural abscess and other extensive disease areas. The jugular vein was tied and the sinus was flushed both from above and below. The patient did badly. He lived twelve days. The post-mortem examination made at that time showed, beside other changes, numerous metastatic processes in the lung, perhaps one hundred abscesses in one lung and about thirty in the other. The condition was an extreme one from the beginning and admitted of very little hope. The specimen here speaks for itself. It presents some necrotic spots on the superior surface of its petrous portion which could not easily be removed by operation.

---

* The papers of Drs. Richardson, Knapp and Calhoun were published in THE JOURNAL of February 23.

There is another case I operated on immediately after this one that presented a few points of unusual interest, and as there are many oculists here, I wish to recite one of them. It was an acute condition. I saw the patient after the first chill; he walked into the hospital. We operated the second day. After operation there was an immediate fall of temperature. We had all the symptoms of pyemia due to sinus thrombosis. We operated and cleaned the involved areas, tied and flushed the jugular. The patient made a quick and prompt recovery. He developed facial paralysis, which was probably due to the operation. Before the operation he complained of double vision, which persisted for three weeks after it. By degrees he developed a complete bilateral abducens paralysis; with this appeared central blindness affecting both eyes. The oculist reports that there is some vision left, but not enough to admit of a useful occupation. The connection between the eye and ear trouble is interesting, and it is important to elicit their cause.

Dr. Kirkendorf—I have a patient on whom I did the radical operation for mastoiditis. He did well for fourteen days, at the end of which time he developed paralysis of the abducens. On the following Wednesday he complained of double vision. I examined the fundus and found it perfectly normal. The only trouble I could see was that the external rectus was paralyzed on the side on which I operated. On the following day I did a secondary operation to make sure my primary one was all right. I secured thorough drainage from the antrum and attic, and, not finding any trouble there that would account for the disturbance, I followed up the lateral sinus and, finding no accumulations in this, stopped my work there, then trephined an inch above the external auditory meatus and took out a piece about an inch in circumference and found the dura mater more or less granulated. Pulsation was marked. I suspected an abscess of some kind in the middle fossa or deep-seated, but the physicians who were with me felt intent on further operative procedures, and so I introduced a needle in various directions, but was unable to find any pus. I then desisted and packed with iodoform gauze, and the next morning the patient was free from septic trouble. There had been a temperature of 103 degrees before I operated the second time, but the next day the temperature was normal and there was no diplopia. Later he had diplopia. Vision was then normal.

Dr. G. L. Richards, Fall River, Mass.—I have two cases to report in connection with the papers of Dr. Allport and Dr. Richardson. One was a case of otitis media with brain abscess. The patient had his hair cut two weeks before the operation. He had an apparently slight otitis media suppurativa, for which he entered the hospital and was finally discharged improved. On his way home he lost his way in a swamp, was searched for and returned to the hospital with a total paresis of the left side, a dilated pupil of the right side, and totally unconscious. He was operated on by me, and almost total destruction of the right lobe was found. Death resulted three days later. The question arises: how long should we wait in these cases? Twenty-four hours before operation this man gave no evidence that he was in this tremendously perilous condition. It only reminds us that every case of otitis media suppurativa is grave until it is well.

The second case was a sea captain who had an otitis media suppurativa. When I saw him there was some mastoid tenderness and I requested permission to operate as soon as I could get the instruments together. I was not allowed to operate until forty-eight hours later, when I did it as thoroughly as I felt warranted in doing. The patient got along well until pain and swelling appeared along the muscle on the opposite side. This I attributed to the operation. After that the patient came under the observation of another man. He was later operated on for multiple abscesses on the back of the neck. It seems that he was developing a moderate, slow degree of septicemia, which broke out on the opposite side, and the forty-eight hours' delay had something to do with that. General constitutional infection may take place simultaneously with the breaking down of an abscess.

Dr. Taylor—I would like to mention a case in connection with the class mentioned by Dr. Calhoun. For a long time I did not believe it possible that we could have mastoid inflammation without suppurative inflammation of the middle ear. But a year ago last April a child was brought to me that had no ear trouble, so far as the parents or the family physician knew, and yet that child had well developed mastoid disease. The ears were standing out and it was very evident that there was pus present. I did what I supposed to be a radical mastoid operation, removing everything until we came to solid bone in every direction. The child recovered promptly and well, but one year later, in April, 1900, without any ear symptoms, without any pain whatever or anything to indicate that there was trouble there, the same trouble slowly developed on the same side. At the time the patient was not living in the town where I was, but was away on a visit, and was brought home to me. I operated the next day, removing everything possible, and I even went through the skull, so that there was no possibility, I thought, for any return of the trouble. The patient recovered very nicely. The child was in a very much run-down condition and we gave cod-liver oil internally, and it was brought down to Atlantic City to recuperate. When it left home there was a slight enlargement of the glands below the ear. The child was brought back about the middle of May with the same trouble well developed in the other ear. A radical mastoid operation was performed on this ear. This is a case in which mastoid disease developed on both sides without any indication whatever of ear trouble. I saw the child the day before performing this operation, and I examined the ear thoroughly without finding any bulging of the membrane or any indication of middle ear disease.

Dr. B. Alexander Randall, Philadelphia—*Apropos* of the Doctor's case, the only one I had the honor of treating with Dr. Calhoun was a patient in whom there was no apparent tympanic involvement at the time the operation was done. It was one of the cases that later required a second operation. I am glad the discussion has taken the form it has, and I am very grateful to Dr. Knapp for beginning the matter as he did; for unless these subjects are considered from the very basis and all the underlying and fundamental points, however elementary, are considered, we are likely to misunderstand and draw wrong conclusions. Dr. Allport's paper sets forth many differences that arise in the opinions of various men from the exigencies of practice and the varying conditions with which we are surrounded. Different men see different groups of cases.

It is interesting to know how many cases of ear disease tend to mastoid inflammation, because it is very variously viewed by different men. It is quite different in a small town from what it is in a large city, and a teaching clinic will find cases much in excess of those found in private practice, where a man is likely to know the beginning and ending of cases, as the man in a clinic in a large city can not possibly do. At least 1 per cent. of my cases have shown disease demanding attention—at least 4 per cent. showing mastoid disease of marked character. Latterly I have seen above 2 per cent. of operative work, based on my total number of new cases seen each year. On the other hand, the cases of mastoid inflammation which did not eventuate in such need were also numerous, in that every year I have about one hundred which go through without any operative need. I do wish to claim that following much such lines as have been laid down by Dr. Allport with the hot douche and such similar measures, the majority of these cases, unless they be streptococcus cases, can be brought through with good conservative measures. The Doctor's remarks in regard to the black race are very good, but my statistics would not show the same thing. Perhaps half the population around the Polyclinic, in which I work, is colored, and here the number of cases of ear disease and mastoid cases that I have seen in the colored race would apparently entirely conflict with the Doctor's view. Among them I have seen many cases where without any apparent involvement of the tympanic cavity, there was extensive mastoid disease. The point brought out by Dr. Knapp is of exceeding importance, and elementary as is the matter it is essential that we bear in mind the fact that we have to deal in these cases with a condition of the whole middle ear. The middle ear begins at the paryngeal mouth of the Eustachian tube, and does not end until you reach the last pneumatic cell in the mastoid, or wherever it may be. Therefore the question of otitis media is a much broader one than is indicated by some men.

We should bear in mind the anatomy of the tympanic cavity. I have much to learn about the anatomy, but one thing which I do know is that unmistakably and as a fundamental fact we have three portions of the tympanic cavity: the attic, the antrum and the atrium, or tympanum proper. Until the anatomy which I have indicated is kept in mind, there will be much poor work done. We should use specific terms instead of generalities and personal names. We should clean out the attic and atrium as well as the antrum in chronic cases. If we deal with these cases of middle ear disease without bearing in mind that the chronic cases differ from the acute, we will fail in a large proportion. Of course the streptococcus cases are serious from the very beginning, and the ones we bring to an apparent cure will often go to the grave with brain disease or other serious trouble, possibly involving the other side of the head. In the chronic cases, if we content ourselves with opening the antrum alone without opening the attic and tympanic cavity as generally understood, we will often fail. So in the thrombus cases, the acute ones usually begin in the jugular bulb and are frequently obliterated at that point. Ligation of the jugular is thus not necessary in these cases, while it is essential in others. We should carefully study our cases in order to properly understand with what we are dealing.

Dr. J. Holinger, Chicago—The term "radical operation" was several times used this afternoon for operations that were not radical in the original sense of this word. A very clear description of what is meant by the term may be found in the *Berlin. klin. Woch.*, No. 1, 1893. I was much interested in the paper of Dr. Gradle. Fistulæ of the external meatus, which are on its roof, are very often found in connection with suppuration of the attic. Fistulæ on the posterior wall of the external meatus are of different clinical importance. The different forms of fistulæ have different dignity, clinical and pathological, and they require different treatment. Fistulæ from the attic may heal as a rule much easier, after a few treatments, while fistulæ from the cells often have a sequestrum in the depth and will yield only to extensive operations.

Dr. E. C. Ellett, Memphis, Tenn.—I would like to make a statement in regard to the colored population not in accord with Dr. Calhoun's statements. I have been criticized on some observations I made as to the non-occurrence of adenoids in the negro, but about one-fourth of the mastoid cases I have operated on have been in the colored race. We do not have as much catarrh or ear trouble among the colored people as we do among the whites. One or two of the mastoid cases in the negro have been apparently unconnected with any preceding trouble in the tympanic cavity. Some of those I have had reason to believe were tubercular. In the negro, as in the white, we see few cases of mastoid trouble in comparison with the total number of cases of middle ear trouble. I have operated at as early an age as 6 months on typical cases, although there have not been many such instances. I would like to pay my respects to Wilde's incision, for if there is any procedure that has no place in surgery it is this so-called Wilde's incision. If the operator does not find a fistula in the bone in the cases where there is a subperiosteal collection of pus, it is because he does not look close enough for it. If there is not any pus outside of the bone this procedure accomplishes no more than can be done by leeching and the application of heat and cold. In the last two cases I operated on, one an adult and the other a child, there was a collection of pus outside of the bone, and it was only by the closest search with the probe that I could find the sinus. It could not be found by simple inspection. My experience with ossiculectomy and tympanic curettement has not been brilliant. One of the gentlemen mentioned a case with a rise of temperature after operation which was confusing. In the last case I operated on, the temperature had not yet been below 99 F., and about three days after the operation the face was swollen and the temperature went up to 102. It was due to mumps.

Dr. H. Knapp, New York City—I wish to report a case of osteomyelitis which belongs to the discussion. These cases are very rare. Recently a young man came to me with an immense swelling behind the ear. The bone all around was swollen and red. There was no fluctuation. From the antrum I liberated considerable pus, and there was a large quantity in the posterior cranial fossa. The sinus laid bare was covered with granulations which were very firm and could not be scraped off. I opened the bone back of the mastoid and found its diploë swollen, softened and full of small disseminate nodules of pus. Further back I found a large subperiosteal abscess which communicated with the posterior cranial fossa by a fistula situated about midway between the torcular and the knee of the sigmoid sinus. I thought I did a rather radical operation. The young man has not had any fever, he never had any chills and he did perfectly well for some time. Then all at once there was a temperature of 102 F. When I examined the case I found the flaps behind, where I had entered the mastoid, were swollen, and there was evidently a collection of pus. About five days later another abscess from above made its appearance from under the flap. When I left there was no fever at all, but to-day I have received information that there is a swelling under the trapezius muscle and a temperature of 103 F. My son says that if the patient is not better soon they will open it again. It is a rather extensive case of osteomyelitis. Operation at once allays the fever. The patient has not had any chills, but it is quite likely they soon will follow because this condition of the dura mater over the sinus is very suspicious.

I can also mention a case that is in the hospital yet, a child who came with a well-pronounced mastoid abscess. I told the parents it ought to be operated on at once. They decided to go home. That was the last I saw of them for five weeks, and then the child was brought in in a semicomatose condition, with a temperature of 105.5 F. I operated on it and found pus in the posterior cranial fossa and granulation tissue, not the same color as in the other case, but very thick. That child had a chill the next night. The next day I operated on her and found the sinus clogged with granulations, which were like the granulations outside, but contained some blood. But no blood came from behind or above. I went in 2½ inches with the probe, until I got blood. It was evidently a thrombus. I went down into the jugular fully 2 inches before blood appeared. The operation has been followed by a very good recovery. [August 8, 1900, patient has completely recovered.]

Dr. Emil Amberg, Detroit, Mich.—I am extremely glad to have heard the contributions, and especially Dr. Knapp's remarks on the skull. These are questions of fundamental importance. We know that in case of adenoids sometimes the nasal syringe is used. Such an instrument should be abandoned, especially with children. I am glad Dr. Knapp mentioned tympanomastoiditis, because we know from Politzer that every time the tympanum is infected there is some possibility of infection of the mastoid by the presence of pus. It is important that the use of the air douche should be abandoned in acute otitis media after a paracentesis has been performed. I do not regard a normal temperature as a contraindication for mastoid operation. As to primary mastoiditis, we know the frequency of this disease in cases of influenza. The small number of mastoid cases in the South may perhaps be accounted for by the comparative rarity of coryza, if such exists. The children do not, perhaps, blow the nose so much in the wrong way. I tell my patients not to blow the nose with both nostrils closed. I do not think I will use peroxid of hydrogen in these cases on account of the possibility of the distribution of micro-organisms by the bubbles. Dr. Allport has used the term, "the personal equation." This is a serious question, but the explanation can be found in an entirely different place. A knowledge of the anatomy is of great importance in otology, and I should like to know in how many medical schools there is sufficient material to exercise the hand and eye in order to be able to perform these operations afterward with due skill.

Dr. Norval H. Pierce, Chicago—I have found cases in children below 6 months of age. They are characterized by pain, temperature about 100 F., and swelling such as usually occurs in mastoid inflammation. In the first case I cut down and got a serous fluid, but no pus. This was beneath the periosteum and probably ran along the posterior surface of the external auditory canal and the middle ear. The other case I saw was very much like this and occurred soon afterward, and I put in an exploratory needle and drew off serous material without any pus. Flocculent particles containing round cells were found. Recovery followed without any symptoms whatever. There was no perforation of the tympanic membrane in either case.

Dr. McCarthy—I have a case that illustrates the remarks by Dr. Knapp in reference to the cancellous tissue that exists in the upper wall of the canal and extends into the horizontal portion of the squamous. A baby had earache and was brought in eight days afterward. On examination there was found no discharge from the canal, but a slight swelling above the auricle. There was absolutely no temperature. The baby nursed and smiled and seemed to be pursuing the natural course of life. An ice-bag was put on because of the swelling. The case ran along for about a week, the swelling still existing. One day the baby refused to nurse and I decided to open up the mastoid. There was a perforation into the middle fossa. The dura was exposed and a necrosed portion about the size of a dime was seen. The further course of the case was uneventful. The child showed no rise of temperature. The case would show the value of making the diagnosis of mastoid or intracranial trouble, and would also put a man on his mettle as to when he should operate. There was a point very well brought out by one of the doctors, which showed the fallacy of regarding the antrum as a separate portion of the tympanum. The antrum has been termed the "drip-cup of the attic." The antrum often is found filled with pus. The cavity of the tympanum proper would never hold the pus that is formed. It is very much like a case of dacryocystitis. You may have a purulent conjunctivitis and if the pus is drained through the nose there may be no dacryocystitis, but let there be some occlusion and inflammation at once takes place, and so here the pus is retained if there is occlusion, and then we get the typical symptoms of mastoiditis. In regard to the occurrence of mastoiditis in the negro, Dr. Calhoun's cases must be very mild, for I have seen many cases in the negro and I do not think there is any differentiation to be made as to the negro race. There is no doubt that not every case of mastoiditis needs operation, but how we can determine how many need it and how many do not is very difficult to answer. While the discharge keeps on from the tympanic cavity considerable regard must be paid to the temperature. I can not conceive of an adult having a temperature from an ordinary otitis media, especially after some two weeks. I had a case which taught me the lesson of not confiding too much in the patient. I had a man with an otorrhea, an acute otitis media, and I opened the drum and the discharge gradually slackened up. I used alcohol and the next day he developed a sclerosis wherever the alcohol had touched. He told me this happened wherever alcohol was used on the skin. The stenosis gradually diminished. When the drum was seen it was found to be healed and the man gradually got better by the introduction of gauze. Two or three weeks afterward he came back complaining of neuralgia, which reached forward to the eye. I told him to consult his family doctor to see if he could find any cause. The patient had a course of phenacetin and other analgesics, and then came back to me. I put him in the hospital and watched him for a few days, and the temperature went up to 102 F. I then operated and found the mastoid not involved. On exposing the sinus I found it covered with granulations and the sinus wall was thickened.

Dr. S. F. Snow, Syracuse, N. Y.—There have been a few points brought up that I would like to emphasize, particularly the hot water method that Dr. Chambers has mentioned. I know that hot water injected as he describes does good. It will control a good many cases where we even have pus in the mastoid. I, personally, am using ice, for the simple reason that cold constantly applied without any chance for the temperature of the part to rise again after it is put on, controls the inflammation the same as hot water does, and it also prevents the multiplication of pus elements. I have been conducting a series of observations that show quite conclusively that if we use ice in this way we will avoid operation in fully 25 per cent. more cases than under the usual lax method. There is no limit to the time ice may be constantly applied, so long as it continues to do good. We are justified in keeping it on beyond "thirty-six or forty-eight hours" if the symptoms continue to improve. At least let us use it during the interval that usually exists between our diagnosis and the actual time of operation.

Dr. L. J. Lautenbach, Philadelphia—There are all variations in cases and treatment. I wish to mention a case operated on by Dr. Fulton. There was some caries of the middle ear discernible. The case followed scarlet fever in childhood. There had never been any pain; there was a constant discharge and no hearing. The patient was operated on a year and a half ago, and within twenty-four hours he left the hospital and never afterward had a symptom. He was in my office about a week ago, and he could hear the watch at ten or twelve inches and could hear the voice very readily. It does not seem reasonable that all cases should be examined by the same standard. For instance, that individual would have sacrificed at least much of his hearing. If our treatment is conservative we should make it so, and if it is radical it should be radical. But every case must be studied carefully and then only can we decide the proper treatment to institute. If I find one thing fails I then go a step further. We may, in our papers and discussions, be dogmatic, but in our treatment we all do the best we can in each individual case.

Dr. H. Knapp, New York City—One of the gentlemen asked me to say a word about the ophthalmoscopic condition in sinus thrombosis. In many cases I have noticed that they can be diagnosed very readily. First to appear is retinal congestion; the veins are enlarged and tortuous, first on the side of the affected ear, then in both eyes. Then the retinal congestion develops into the picture of neuroretinitis; optic discs and adjacent retina are diffusely swollen and opaque, not the picture of abrupt jockey-cap elevation of the choked disc from cerebral tumor. Then when the sinus thrombosis is recovered from, spontaneously or by operation, the ophthalmoscopic signs disappear *pari passu* with the progress of the recovery, to end in perfect restoration of sight. The interrupted course of the pyemia, in the affections of joints particularly, is accompanied by corresponding aggravation and improvement in the ophthalmoscopic condition.

APHASIA WITH LETTER-BLINDNESS, WITHOUT WORD-BLINDNESS; WITH RIGHT HEMIPLEGIA AND PULMONARY TUBERCULOSIS.*

GUY HINSDALE, A.M., M.D.

Fellow of the College of Physicians of Philadelphia; Member of the American Neurological and American Climatological Associations; President of the Pennsylvania Society for the Prevention of Tuberculosis.

PHILADELPHIA.

I wish to make a brief record of a case of pulmonary tuberculosis with intercurrent hemiplegia of the right side and motor and sensory aphasia, with letter-blindness, but not word-blindness. The patient is a physician and a member of the faculty of a well-known institution. He is now 35 years of age; he had pneumonia sixteen years ago, and had a slight attack again two years ago. His tubercular infection is probably now of about four years' duration. At the beginning of the year 1899 both lungs were infiltrated; the right, generally consolidated. The fingers were clubbed.

January, 2, 1899, he had a sudden paralysis involving the right face, arm and leg. It was apparently simultaneous throughout this distribution, and did not extend from one area to another. There was a short period of unconsciousness. I saw him the next day at the request of Dr. D. D. Stewart, of Philadelphia. During the first twenty-four hours he could speak only the word, "no." In the next twenty-four hours he could speak four words and could move his right arm and had good control of his facial muscles; these muscles, however, were not so well innervated on the following day, but quickly regained their normal power. Sensation was good all over the body. The tongue was protruded to the right and the affected arm and leg were moved freely. The knee-jerks were normal on both sides; the plantar reflex was also normal. On the ninth day he walked to the sitting-room and insisted on helping himself to tobacco and a glass of wine, and from that on he steadily gained power. I examined the visual fields for form, but was not able to distinguish any departure from normal. January 13 the patient was able to write his name for the first time, and his vocabulary was steadily increasing.

When shown a silver pencil he could not name it; when he was asked if it was a knife he said, "no"; a piece of wood, "no"; a pencil, "no" (word-deafness). When he was asked if it was something to write with, he answered "yes." Upon being asked if a key were several things, including "key," he said "no." Having been asked if it was something to open the door with, he said "yes, yes."

On January 20, the patient was shown a silver dollar; he could not say what it was. "Is it a watch?" "No." "Is it a wheel?" "No." "Is it a piece of iron?" "No." "Is it a dollar?" "Yes, it is a dollar." The patient was given a few coins; he added them in a correctly built column with the total value correct. He mispronounces some words and substitutes words incorrectly in a sentence. For example, he said: "the quiet was," instead of the reason was; "spade," for paper; "glass of ice water," for a pair of scissors; "was late," for he was weak; "blockade," for dump; "bathree," for paper; "put those groups afay for me," for put those grapes away for me—paraphasia.

He read the daily paper regularly and read McMasters' history of the United States and enjoyed it. He had letter-blindness, but not word-blindness. When shown the alphabet he counted "1, 2, 3," instead of a, b, c. When shown "o," he could not call it; neither could he call "i," "l" or "d"; but shown the words boy and child, he instantly pronounced them. He said "boat," for cars; "pipe," for glasses; "spoon," for comb and so on.

---

* Presented to the Section on Nervous and Mental Diseases, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

The tubercular process was marked by dulness extending posteriorly as far as the angles of both scapulæ and by soft mucous râles in both apices. Tubercle bacilli were present. There was no fever at any time, and the pulse ranged from 76 to 88. There was no hemoptysis. His treatment included potassium iodid, 5 to 10 grains, t. i. d., and the subcutaneous injection of antitubercle serum in the upper arm at intervals of from two to four days, until the latter part of March, 1899, when he went, on our advice, to the orange district of southern California. Now, after nearly a year and a half, he enjoys a fair amount of health, his tubercular process is not checked, his aphasia and agraphia are still present, though in less pronounced degree.[1]

Without going further into this case, it is interesting to note the occurrence of hemiplegia in the course of tuberculosis. Whether in this case it was due to a hemorrhage, a thrombus or an embolus we can not positively say; it was probably the latter. The letter-blindness is a most interesting and unusual feature. We may have word-blindness without letter-blindness. Letter-blindness is not always looked for, and that is partly the reason why so few cases have been recorded. Dr. Hinshelwood,[2] of Glasgow, has recently published a clear exposition of the subject, with records of interesting cases, and he shows that if by disease, the visual word-center is completely destroyed, or if it is completely cut off from the primary perceptive centers in the occipital lobes then the patient is both word-blind and letter-blind. But if the destruction is only partial, and that part of the center in which are stored the visual memories of letters remains intact, then the patient, though still able to recognize the individual letters by sight, will no longer be able to recognize and interpret words, because he has lost the visual memories for words, which he had acquired by years of laborious effort.

Clinical evidence goes to prove that all these memories for words, letters and figures are functionally independent and have a distinct and separate anatomical seat. It would appear that the positions of these three centers are adjacent, and while the boundaries have not been defined with precision, pathological experience tends to prove that the centers in which are stored the visual memories of letters and words includes the supramarginal and angular convolutions, both of which belong to the inferior part of the parietal lobe.

In most people this center is supplied by the left Sylvian artery, and in the case which we have reported, it is quite likely that, being a right-handed man, an embolus or hemorrhage of this artery caused the hemiplegia and the consequent aphasia. In cases in which either word-blindness or letter-blindness, or both, exist without hemiplegia we may explain the lesion as situated in a branch supplying the visual word or letter center, while the branches going to Broca's convolution and the motor areas for the face, arm and leg remain undisturbed. In our case the hemiplegia was comparatively transient, function was restored in a few days, but the aphasia persists at the end of nearly a year and a half, much to the annoyance of the man whose living depends on the free exercise of his highest intellectual faculties.

DISCUSSION.

Dr. F. Savary Pearce, Philadelphia—In regard to the recovery from hemiplegia, and in regard to tuberculosis of the brain, I simply wish to record my feeling that hemiplegia or paralysis from the tubercular processes, which apparently this case was, are more apt to recover, at least transiently, than paralyses from other causes, such as hemorrhage or even from specific disease. I remember full well the instance of a young child who had a tubercular meningitis with sequent hemiplegia. A shifting of the paralysis from one side to the other, involving the leg and the right side of the body, then one extremity after another in order of pressure made or relieved by the exudate or its absorption. The case came to autopsy, and we found tubercular exudative processes then to be mostly about the base of the brain. The palsy had shifted in this case, due to exudation and absorption with shifting pressure results.

Dr. James H. McBride, Los Angeles, Cal.—There are occasionally peculiar transformations of aphasia in syphilitic brain lesions. One patient I had was attacked a number of times with motor aphasia, from which he recovered; then at other times with auditory aphasia; and at others with visual aphasia. The form was distinct in each instance, and he again and again relapsed and recovered, sometimes having one form and at other times other forms.

About 1874 there was reported, in the *British Medical* Journal, the case of a right-handed child who, at 10 years of age, had a lesion in the left third frontal with motor aphasia with subsequent recovery of speech. Two years later a similar lesion on the right side produced permanent aphasia. An autopsy showed two lesions, the first in the left hemisphere, the second in the right.

Dr. W. G. Spiller, Philadelphia—When he observe a case of aphasia with localizing symptoms, we naturally incline to the belief that there is a focal cerebral lesion, but such cases may occur in which a lesion can not be seen either by the naked eye or the microscope. I recall a case in which no signs of nephritis had been found, and the symptoms of aphasia were sufficiently localizing to justify an operation. The day before the one set for the operation, evidences of nephritis were found, the operation was postponed, and after the nephritis had been treated, the aphasic symptoms disappeared. I have recently seen a case of Dr. Lloyd's, with localizing aphasic symptoms without any lesion whatever in the brain. This patient also had nephritis. Cases of hemiplegia and aphasia have been reported in which carcinoma has been found in various parts of the body. In one or two of these, lesions have been detected in the meninges; but in others no lesions which would explain the symptoms have been found. I am not aware that any one has reported cases of tuberculosis of various organs of the body causing aphasia, but if aphasia can occur as a result of some poison produced by carcinoma, it might possibly be produced by tuberculosis.

Dr. Guy Hinsdale—I did not look upon this case as being one in which tubercular deposits occurred in the progress of the disease about the centers which govern speech and writing. It seemed to me more likely inasmuch as there was an exceedingly rapid onset in which the paralysis extended immediately over one-half of the body with the rapidity of a thunderbolt, there was probably an embolus, or something that was carried to the brain through the circulation from some point of softening in connection with the pulmonary tuberculosis. Of course, we have thrombi of the extremities in cases of pulmonary tuberculosis, giving rise to the most painful symptoms; why not also a thrombus or embolus in the brain?

Recent public health legislation in New Zealand consolidates and amends the law previously in effect there. It provides for a minister of public health, to be appointed from the Executive Council, by the governor, and bestows exceptional powers on district health officers.

---

[1] The patient died in California, of phthisis, in the summer of 1900.

COMBINED SCLEROSIS OF LICHTHEIM-PUTNAM-DANA TYPE ACCOMPANYING PERNICIOUS ANEMIA.*

MARK A. BROWN, M.D., F. W. LANGDON, M.D.,
AND D. I. WOLFSTEIN, M.D.
CINCINNATI, OHIO.

ABSTRACT OF CASE BY DR. BROWN.

I was first called to see the patient early in July, 1899. He had been in failing health, with varying periods of improvement for between three and four years. To about a year previous to my first seeing him, however, he dates his illness, but was able to be about attending to business until February. The principal point noticeable at first glance was the marked emaciation, and the peculiar color to the entire body; not the blood-cancerous cachexia, nor the anemia of Bright's disease, nor the bloodlessness of the tuberculous, but a brown-yellow color which I have never typically seen save in pernicious anemia. To rule out any other cause, however, a careful physical examination was made. The heart, aside from a soft basal systolic murmur, probably anemic in character, was normal, nor could anything wrong be detected in the lungs. The liver and spleen were not palpable, and were of normal size on percussion. Remembering the similarity that often exists between carcinoma of the stomach and pernicious anemia the usual tests were applied before the former could be eliminated. The urine was normal. The probable diagnosis of pernicious anemia was made and the blood examination, July 8, 1899, resulted as follows: The blood, obtained only on deep puncture, was very watery, with no tendency to coagulate. A small hematoma rapidly formed in the lobe of the ear. Reds: 1,279,440 (288 squares); whites, 3600 (1200 squares). The hemoglobin estimation average of three tests—ten drops used at each test and the result divided (Fleischl instrument)—was 32 1/6 per cent., so that the color-index was 1.3. A subsequent note states that blood films took the Ehrlich triple stain with marked polychromatophilia. Poikilocytosis was very pronounced. The stained specimen showed numerous nucleated red corpuscles, the megaloblasts greater in number than normablasts. From this examination, not only was a diagnosis of pernicious anemia unmistakable, but the prognosis could be stated as absolutely fatal. The usual treatment with Fowler's solution was instituted, and the patient was soon able to take 15 drops three times a day. Occasionally symptoms of poisoning would supervene, when the arsenic would be discontinued for a while. He seemed to gain under this treatment, except in his legs, which became progressively weaker and more emaciated. The patellar reflexes, right and left, were hypersensitive. The appetite was enormous, the patient seeming never to get enough to eat. During the summer the fact most worthy of note was a genuine attack of insolation, with temperature 107, flushed face and full bounding pulse. He recovered completely from this in about ten days. I saw him occasionally during the fall and early winter, and he appeared to be holding his own, except for the weakness of his legs. He thought that electricity might be of some benefit in nourishing the wasted muscles, and asked me to advise him as to hospital treatment. He entered the Cincinnati Hospital early in January, 1900, on the service of Dr. F. W. Langdon.

ABSTRACT OF CASE BY DR. LANGDON.

A. W. C., aged 34, an American, married, with no children, was supervisor in a hospital for eleven years, and later proprietor of restaurant. He was admitted to the hospital in January, 1900, complaining of general weakness and inability to walk on account of stiffness and weakness in his legs.

Family History.—His father is living at 74, and in good health. His mother died at 60, of chronic blood disease; she was ill a year. The patient thought her disease was similar to his. He is the first of three children; the other two living and well. There is no nervous disease in family.

Previous History.—He had had no syphilis, and only the ordinary children's diseases, and gall-stone colic five years ago. Alcohol and tobacco had been very moderately used.

Present Illness.—He was in ordinary health to July, 1898, then weakness followed, increasing to February, 1899, when he was first confined to bed owing to rigidity in legs. A diagnosis of pernicious anemia was made by Dr. M. A. Brown, in July, 1899.

Condition.—His height was 5 feet 10½ inches, his weight. when well, 140 pounds, though he was much emaciated. He had a dark complexion, with gray hair—black a year ago—gray eyes and good teeth. His pulse was 108, of low tension, with no cardiac bruit, and no apparent arteriosclerosis. The conjunctivæ, lips and tongue were only moderately pale, not suggesting extreme anemia, there were no cranial nerve palsies nor special sense disturbance.

Motion.—His legs were rigid, but he could move all the joints voluntarily, though he could not walk on account of the weakness and rigidity. There was inco-ordination of the upper and lower extremities. He sat up some daily.

Sensation.—There was some defect of tact and pain—delay and hypoesthesia—about the ankles. The knee-jerks were plus. There was ankle-clonus and Babinski's sign present on both sides.

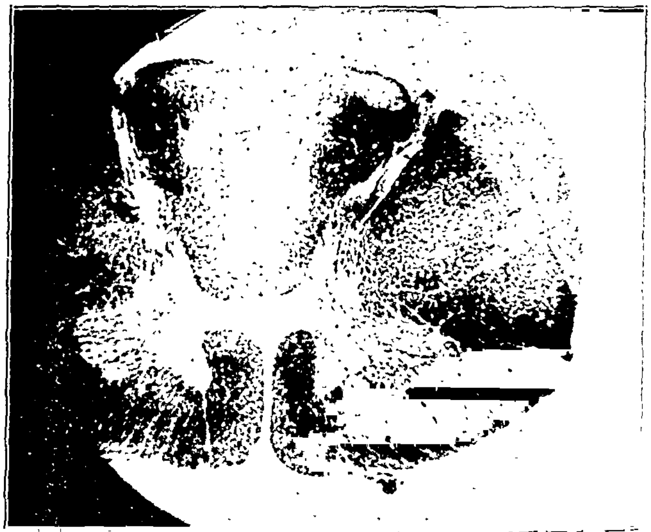

Fig. 1.—Cervical reg. (upper). Degeneration in lateral and posterior tracts. Vacuolisation of the white matter in the pyramidal tract

Blood Counts.—Feb. 13, 1900, reds, 1,661,805; whites, 3,000; hemoglobin, 54 per cent.; color-index, 1.54; eosinophiles, 9 per cent.; neutrophiles, 49 per cent.; small lymphocytes, 39 per cent.; large lymphocytes, 3 per cent. Poikilocytosis was not marked and megaloblasts in all three were seen. March 20, 1900, reds, 1,183,330; whites, 2100; hemoglobin, 36 per cent.; color-index, 1.53; eosinophiles, 10 per cent.; neutrophiles, 47 per cent.; small lymphocytes, 37 per cent.; large lymphocytes, 6 per cent.; poikilocytosis; megaloblasts, 1; unnamed form of nucleated red, 1.

Subsequent Course.—There was gradually increasing weakness, with little or no mental defect, to April 10, 1900. There were mucous stools and epistaxis at intervals. For treatment he was given full diet and arsenic and iron in various forms, none seeming to improve the blood state, which steadily deteriorated. The general sense of well-being of the patient seemed improved by the diet and medicinal measures. Death, preceded by coma for twenty-four hours, occurred on April 11, 1900.

Autopsy.—There were no marked naked eye changes in the cord or brain, and the organs were generally healthy.

ABSTRACT OF REPORT ON MICROSCOPIC EXAMINATION, BY DR. WOLFSTEIN.

Macroscopically the cord showed nothing abnormal; there was no shrinkage of the posterior tracts, no distortions, nor inequalities, and no areas of softening were made out anywhere.

---

* Presented to the Section on Nervous and Mental Diseases, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

The areas of the crossed pyramidal and posterior zones were of a duller grey-pinkish color than the surrounding areas. The cord, after being hardened in bichromate solution, showed most marked areas of degeneration in the tracts named. The principal degenerations, on microscopic examination were seen to be in the posterior and in the lateral tracts. That in the posterior commenced as low down in the cord as the lower lumbar level, and could be traced all the way up to the level of the pyramidal decussation at least. The tracts of Goll and Burdach were involved in part, but not completely. The so-called oval field of Flechsig was free, as was also an area—wedge shaped—lying immediately posterior to the posterior commissure—the ventral field of Goll's tract. The column of Burdach was involved only in parts, and between the column and the border of the posterior cord grey, there was, in all levels, healthy nerve tissue. As said, the ascending degeneration had the usual upper limits, not extending beyond the *nuclei* of the posterior tracts.

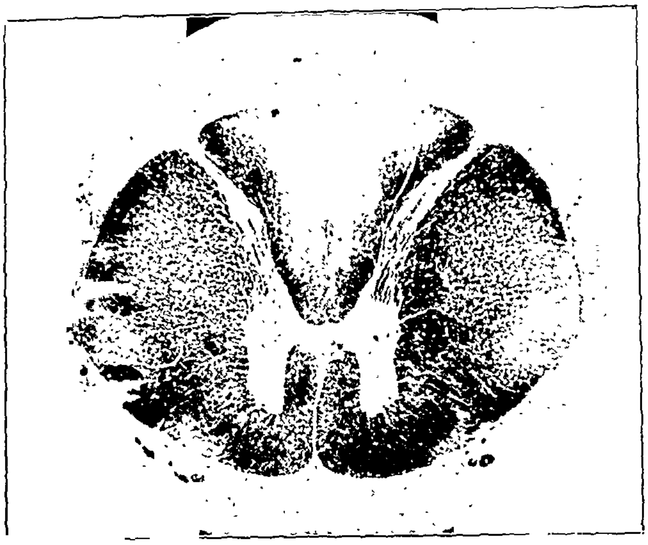

Fig. 2.—Lower cervical. Degeneration in posterior and lateral tracts, with marked vacuolisation.

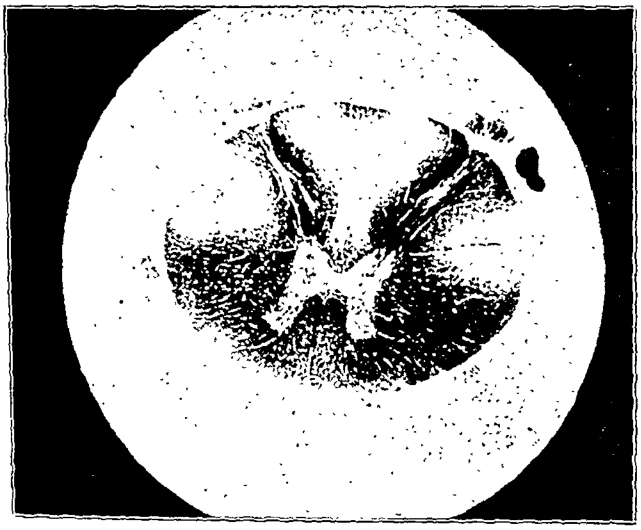

Fig. 3.—Upper dorsal. Degeneration in lateral and posterior tracts.

The *pyramidal tract* was *degenerated* downward from a level as high up in the medulla as that of the olives. Here there was an area, quite small, occupying a position near the periphery of the medulla, dorsal to the olive and just ventral to the corpus restiforme. Above the level of the motor decussation the degeneration was quite well marked, about midway between the nucleus of cuneatus and the olive. The degeneration was quite marked as low down in the cord as the sacral region, the ending of the pyramidal tract degeneration being lower down than the beginning of the ascending degeneration.

I have not yet been able to convince myself that there was any degeneration of Lissauer's marginal zone. In the dorsal and cervical levels the entering posterior nerve root bundles appeared slightly involved. The ganglia were unfortunately not examined. As to finer microscopic details there did not seem to be any marked vascular changes; in certain places the walls of the smaller vessels showed hyaline changes, but there was no evidence of inflammation. There were no areas of small round-celled infiltration, nor of anything that might be taken for small, multiple, hemorrhagic *foci*. In both posterior and pyramidal tracts there was *marked glia* increase. In many places nerve-fibers seemed to have fallen out so that, especially in the pyramidal tract, there was the *perforated riddled appearance seen in advanced degeneration*. The *Marchi* method showed the usual picture.

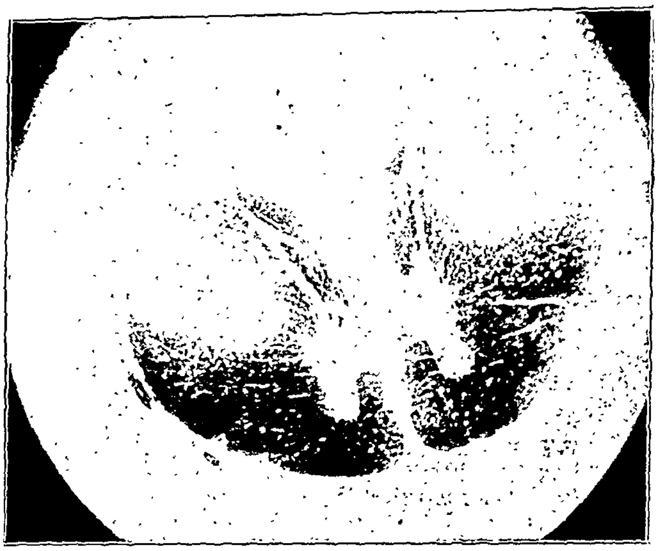

Fig. 4.—Mid-dorsal. Marked degeneration in lateral and posterior tracts.

I have no theories to offer in explanation, as I would dislike to draw conclusions from one case only. I rather think, however, that the phenomena observed in this case are at variance with the view of Nonne that the degeneration is due to ascending and descending degenerations, following on multiple areas of softening of *inflammatory* or hemorrhagic character which several areas become *confluent* and give the appearance of systemic lesions. On the contrary, from the extent and quite typical disposition of the degeneration in the areas named his view is more in consonance with that of Burr and other authors who consider the lesion as a primary systemic degeneration—primary as far as the *cord* is concerned, and distinctly

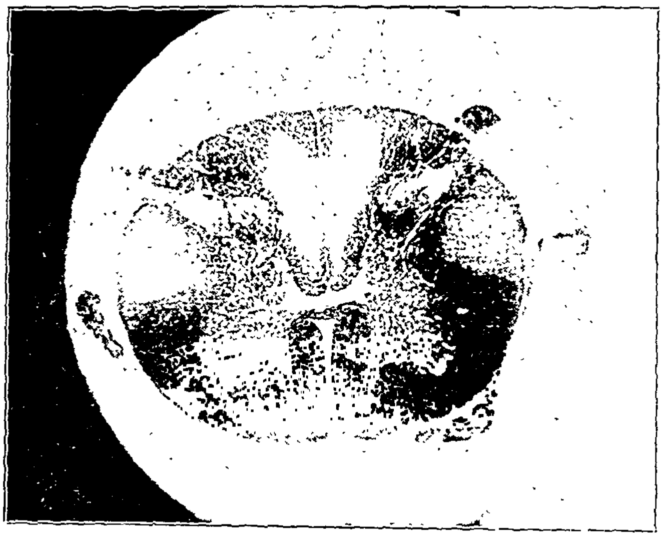

Fig. 5.—Lumbar region. Degeneration in lateral and posterior tracts.

neuronic, but secondary etiologically to some condition superinduced by the pernicious anemia. This opinion is also shared by Dr. Langdon.

DISCUSSION.

Dr. W. G. Spiller, Philadelphia—I think we should be very careful in drawing conclusions from any one case. I have examined sections from cases of severe anemia, and am at present studying a case of this character. In Dr. Wolfstein's specimen the degeneration in the lateral columns is quite clearly defined; in the posterior columns, as he has pointed out, it is less systemic. In the specimens of the case that I am at present studying the degeneration is much less systemic, and the vascular disease is very considerable, the small vessels of the spinal cord are thickened, and the degeneration of the lateral columns is more diffuse than in Dr. Wolfstein's case.

Dr. Kenniston—I would like to ask the gentleman about the Leszynsky reflex; I am studying that in epileptics. One or two are post-hemiplegic cases, and I have found the extensor reflex on the paralyzed side. Curiously enough, when that patient has a seizure, immediately thereafter the extensor reflex is present on the paralyzed side, and the flexor response on the other, and an hour afterward there will be a flexor response on the paralyzed side and perhaps a response on the other side.

Dr. Hugh T. Patrick, Chicago—I should like to ask Dr. Wolfstein whether he does not think that some of the structural changes described in this case were due to artifacts. It seems to me, from the naked eye appearances, that some of the specimens certainly show signs of postmortem injury.

Dr. D. I. Wolfstein—I am very glad to learn that Dr. Spiller agrees partially with me as to the result of the study of this case, and I shall study it more carefully. As to the Leszynsky reflex, I suppose it is present in these cases on account of the involvement of the pyramidal tract. With regard to the question of artifacts, I agree with the chairman, as some of these changes were probably due to postmortem injury.

CROUPOUS PNEUMONIA.*

J. M. ALLEN, A.M., M.D., LL.D.
Professor of Principles and Practice of Medicine, University Medical College, Kansas City, Mo.
LIBERTY, MO.

The old masters of our profession had very imperfect ideas of etiology, therefore taught faulty therapeutics. They thought croupous pneumonia to be the result of fluctionary changes in the blood brought about by cold, etc. They had an incorrect idea of the character of the cause of the first step in the process of inflammation, that is, irritation caused by bacteria. They recognized the buffy coat of the blood and the rapid increase of fibrin in pneumonia, their essentials in the inflammatory process.

The correction of this condition was to be accomplished by rapid depletion; hence blood-letting one or more times until the radial artery ceased to be strong and corded.

Next followed the revulsion by what they termed an emeto-cathartic composed of 10 grs. hydrargyri chloridum mite, 10 grs. pulvis jalapæ, and 2 or 3 grs. of antimonii et potassii tartras. From the beginning of the attack the patient was kept nauseated with frequent doses of tartar emetic.

In the latter part of the second and the beginning of the third stage they gave either calomel or hydrargyrum pill combined with small doses of opium and pushed to full ptyalism, the object of which being to defibrinate the blood and arouse the secretions.

Their expectorants were squills, tinct. senegæ, lobelia and ipecac. If the case occurred in a malarious district 20 to 25 grs. of quinin were given daily or an equivalent of pulvis cinchonæ; this indeed was the only scientific remedy that was used. In the 60's the quinin was reduced in quantity and given in 2-grain doses frequently repeated as a stimulant to the vasomotor system. Alcohol and other stimulants were forbidden until the heart's action became rapid and weak. A few physicians ventured to give digitalis in the third stage, but many condemned it as highly injurious.

One of the so-called sheet-anchors was extensive blisters applied over the affected lung, which were kept irritated and discharging during the course of the disease. As a matter of course, we know now this was adding fuel to the flame. Later, blisters were not applied until the latter part of the third stage, when crepitant redux could be heard. It was claimed for the blisters so applied that they called forth the reserve force of the individual and hastened resolution. This change occurred in the latter part of the 50's and the beginning of the 60's, after which instead of blisters in the first stage, there was substituted counter-irritation by scarification and cupping over the affected lung. This was a vicious and cruel process; the click of the scarificator grates on my ears even to-day.

In the middle or latter 60's the scarificator and blister gave way to counter-irritation—mustard sinapisms, turpentine stupes, and painting the chest with tincture of iodin. Later these were followed by emollient poultices.

About 1858 Dr. Austin Flint struck the death-blow to blood-letting, by his experiment in treating 25 cases of pneumonia with good diet, tonics and iodins, greatly reducing the death-rate. This is not all the advantage that was gained by this distinguished American physician, and while it added nothing to our knowledge of the etiology of the disease, it thoroughly revolutionized the treatment, destroyed the theory of depletion, ptyalism, blisters, etc.

This caused the physicians to look about for more rational therapeutics. Mercury was used only in small doses, guarding carefully not to ptyalize; purgatives were abandoned for mild laxatives, antimonii et potassii tartras was abandoned and a substitute found in Norwood's veratrum viride, which is a reliable heart depressant, diaphoretic and sedative to the nervous system, its action in slowing the heart, quieting the nervous system and producing diaphoresis was so efficient and prompt that the physicians were ready to cry out, Eureka! It is now demonstrated that it is in no sense curative.

The carbonate of ammonium, because of its so-called power of liquefying the blood and as a heart stimulant, was believed to be curative. That it is a quick transient heart-stimulant is true, but it is in no sense curative. A large number of other remedies have been tried and found wanting; therefore it is not necessary to name them.

When the early physician used potassium nitrate it was because of the supposed *antiphlogistic effect*.

Hydrotherapy, by either warm or cold baths, has had many advocates; the first could only be beneficial by calming the nervous system, the latter by lessening the temperature, neither of which could be considered as curative. The German cold chest-pack might be beneficial in two ways: 1, reducing the temperature; 2, increasing the blood in the lung, thereby increasing phagocytosis.

The only remedies which we bring over from the past —except digitalis—are those which are more or less germicidal, as mercury, potassium nitrate, quinin and alcohol, the last of which is of doubtful utility, possibly injurious, and not needed now, because we have better remedies for the same purpose in digitalis, strophanthus, nitroglycerin and strychnin.

---

* Presented to the Section on Materia Medica, Pharmacy and Therapeutics, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

The first theory in the right direction as to the etiology of pneumonia was promulgated by Dr. Francis M. Johnson, of Kansas City, Mo., who read a paper before the Kansas City District Medical Society in 1875, in which he claimed that pneumonia should be taken from the list of inflammatory diseases and placed in that of essential fevers. At this time the germ theory of disease was beginning to impress the medical minds of the country, which theory I accepted in connection with Dr. Johnson's theory of pneumonia, and modified my previous treatment accordingly, by giving at the beginning a calomel and rhubarb purge, except in cases where there was jaundice caused by acute duodenitis, misnamed bilious pneumonia.

The other remedies which I used in the various combinations adapted as I thought to the conditions, potassium nitrate, potassium bromid, ipecacuanha, minute doses of calomel, Dover's powder as an anodyne and diaphoretic, the terebinthinates, cold sponging, and emollient poultices to the chest.

In the second stage I begin the use of digitalis and strychnin in small doses, increasing the dose to meet emergencies, rarely using alcohol.

While Dr. Johnson's theory is not widely known, it marked a decided change in the treatment of pneumonia in that vicinity.

When Fränkel and others discovered that the diplococcus was always present in pneumonia, and which excited the initial irritation, this established the etiology, and that it was infectious. True streptococci and staphylococci are almost always present in the second stage, as a result of structural changes caused by the diplococci. This marked another epoch in the therapy of this disease as I think based on incontestible facts.

I then adjusted my treatment to this known etiological factor and its associated complication of streptococci and staphylococci, using only germicidal remedies of creosote, eucalyptol, guaiacol, mercury, combined often with the terebinthinates and balsam of copaiba.

In the first and second stages, long before this time, it had been recognized that the most frequent cause of death in pneumonia was edema of the lung, caused by weakened heart action, particularly the right side, and paralysis of the vasomotor nervous system. To meet this indication, I began the use, in the second stage, of digitalis, strophanthus and strychnin, later nitroglycerin, if needed, abandoning entirely alcoholic stimulants.

I also used in the first stage, inhalation of the tincture of iodin, and menthol, because of their germicidal effect, and ceased using all counter-irratation as illogical, as it lessened the amount of blood sent to the lung, thereby lessening the possibilities of phagocytosis.

About 1885 I ceased the germicides mentioned, and began salicylic acid in full doses every three or four hours. Now I use the sodium salicylate, 10 to 15 grains, every three or four hours. I continue this until the fifth or sixth day, when I cease it, unless new structure is being attacked, because it is fairly well demonstrated that the entity upon which the germ subsists is destroyed by this time and the germ dies, leaving only the pathological results to deal with.

The effects of sodium salicylate are germicidal from its start in the mouth until its elimination by the kidneys and mucous membranes. That it rapidly enters the blood is evinced by the fact that in a very few minutes it can be detected in the saliva and secretion of urine. Benz and others claim that when the salicylate of soda comes in contact with the carbonic acid of the blood it is converted into salicylic acid again, thereby increasing its germicidal effect.

When there are indications of the presence of streptococci and staphylococci in large quantities, I have used the antistreptococcic serum with positive results. To relieve shock, control pain and produce diaphoresis, I give three doses of 5 to 7 grains of pulvis Doveri during the exacerbation of fever.

To summarize the therapy of pneumonia: I administer a calomel and rhubarb purge at the beginning; afterward the alimentary canal is to be kept open with castor-oil and turpentine. Three hours after the purgative I begin with the sodium salicylate, 10 to 15 grains, given in 4 drams of Phillip's milk of magnesia. During the exacerbation of fever I give the pulvis Doveri as above mentioned. The digitalis, strophanthus and strychnin are given in the middle of the second stage in small doses, increasing as the heart may demand. About the fourth to sixth day I cease giving the sodium salicylate and substitute for it tincture of ferrum chlorid, potassium iodid, quinin, nitroglycerin; as a matter of course, the heart tonics and stimulants must be continued in full force. During the last two years I have been using with great benefit oxygen inhalations.

The patient's diet should not be restricted, unless he be jaundiced by acute duodenitis, which is often associated with croupous pneumonia; then the diet should be restricted to milk and eggs.

DISCUSSION.

DR. WARREN B. HILL, Milwaukee, Wis., said that we have not yet arrived at any logical method of treating this condition of acute pneumonia. It is true that we know the nature and the etiology of the disease, for he assumed that the germ had been isolated, but in his opinion the disease is one of mixed infection. We have the diplococcus, staphylococcus and streptococcus, often associated with the very important germ of influenza, which modify the clinical aspect of the disease. As the result, we have not been able as yet to master the disease through the use of serums. Perhaps more has been done in this direction than he suspected, but his own experience had been such as would bear him out in making this statement. We can not attack the germ without doing injury to the rest of the body. He wished to direct attention to the fact that the discomfort and danger to the patient come almost entirely from two sources: 1, weakness of the heart, the cavities becoming too full of blood; 2, the circulation in the lung is checked and the blood lacks oxidation. The discomfort, the bad symptoms and death are usually due to these two causes.

In our treatment we aim to support the vital power and keep the patient comfortable and keep up the circulation. The pain is relieved by applications to the chest. He does not believe in the cold pack, except in the early, acute condition. When stasis has already taken place he would employ measures to dilate the vessels and make the flow of blood more easy through the lung. He would not agree with the lecturer who said that he wanted to put more blood into the lung; there is too much in it already. He would use digitalis for the purpose of toning up the walls of the blood-vessels to permit the flow of blood through the affected part. We should not neglect to make applications to the lungs; it does not make very much difference whether you put on a poultice or cotton, if you use some application which will relieve pain, keep up the circulation on the surface and maintain an even temperature. Again, as to the balsam of copaiba and other irritating drugs, recommended for their action on the lungs, it is a question whether we should not do harm instead of good from the amount of irritation in the lung by the use of this class of agents in pneumonia.

DR. J. TRACY MELVIN, Saguache, Colo., said that this subject of the treatment of pneumonia is the most disputed one in pathology. Some eminent physicians say: "Do nothing to the patient, it is a self-limited disease and patients will get along without drugs." Others say that if they know anything at all about it, drugs do good to patients with pneumonia. The paper has shown the results of the experience of the writer in support of the value of drugs in the treatment of pneumonia. The remarks of the last speaker show that while pneumonia is undoubtedly due to the diplococcus, yet many cases are the result of mixed infection. It is impossible, therefore, to lay down any hard and fast rules for the treatment of cases of acute pneumonia, yet there are several principles which can be followed by the practitioner and will aid him in the treatment of these cases. In the portion of the country to which the speaker belongs, pneumonia produces the most numerous fatalities; the number of cases treated each year is very large. The experience he has had in his last 200 cases of croupous pneumonia has led him to be positive—if he could be positive about anything—that the condition can be relieved by blood-letting. There are two conditions to be overcome: 1, the condition of the blood, and 2, the weakness of the heart which follows. Either you must relieve the stasis in the blood-vessels or increase the power behind to force the blood through the constricted blood-vessels. Among many practitioners veratrum viride has been lauded as almost a specific in the treatment of the first stage of pneumonia. Others rely on aconite for its dilating action on the blood-vessels, thus relieving the strain on the heart. He has abundant testimony that by the use of veratrum viride the course of the disease is cut short and the case convalesces two days earlier, and the whole course is milder than where this is not given. His own preference, however, is for aconite, which acts in the same manner. By following out this treatment he has seldom had a case last longer than five days before the crisis occurred. The next point in the therapy is to strengthen the heart so that, after the action of the veratrum viride or aconite has overcome the constriction of the vessels, the blood may be forced through them. Digitalis and especially digitoxin have been recommended for their physiologic action on the heart, but in strychnin we have a remedy, which is most useful in this condition. If there is any disease in the world in which we can recognize the efficacy of blood therapeutics, it is in acute pneumonia. In some parts of the country the mortality reported from hospitals is 25 per cent. In his portion of the country, if he did have any mortality at all, he would lose his practice, as the people expect pneumonia cases to get well if they receive proper attention.

Dr. Boyce—An important question in connection with the subject under discussion is the value of serumtherapy. To the speaker acute pneumonia is the type of a toxic disease. It has its nearest analogue among infectious diseases in diphtheria. The diplococcus of pneumonia and the bacillus diphtheriæ, or Klebs-Loeffler bacillus, are the sole micro-organisms which cause fibrous exudation upon mucous membranes. The clinical type of pneumonia depends entirely on the virulence of the bacillus and absorption of toxins. The clinical course of the disease is evidence of this. You may see your patient on the sixth day and he is a sick man; apparently he is still as sick as on any day previous; he has an exudate in the lung that is the same as the previous day, and suffers from fever and other evidences of this disease, but you go back again on the same afternoon and find the patient a well man; the oppression is gone, the fever has gone and he feels well, and you can see that he is relieved, but the exudate has not changed. No diagnostician can show any change in the exudate, but there is no dyspnea and the patient feels well and is hungry. The change that has taken place in the symptoms is very evident, but it has not been due to any change in the condition of the lung. On the other hand, we will have very great damage to the lung without the symptoms of the kind we see in pneumonia. For instance, we may have one of those large pleural exudates which come upon us and force the lung and heart to one side and leave only a portion of one lung for the patient to breathe with, and yet the patient will not have the dyspnea that he has in pneumonia. Therefore, the condition is not mechanical, but is due to the presence of certain toxins in the blood. Therefore, the best thing we can do for pneumonia patients is to dilute the toxinemic condition of the blood by saline injections, using the normal salt solution for this purpose; also local applications to the chest, ice-bags or hot poultices, the object being to relieve the nerves and to relieve pain, and give symptomatic relief, and by this means we do give relief to the symptoms. The treatment of serumtherapy is possible. As to the administration of veratrum viride, we know that the exudate can not be absorbed by this agent. I have seen cases of acute pneumonia in which the physical signs all disappeared in one day, and this occurred just as often in those who had taken veratrum viride as in those who had not. As regards the comparison instituted by Dr. Melvin between cases treated by blood-letting and those who are not, taking the violence of the attack into consideration and the difference between the patients treated in private practice and those in the hospital, 25 per cent. mortality is practically correct. He knew of a hospital which for a few years had lost over 40 per cent. in acute pneumonia, simply owing to the character of the clinical material. He thought that 25 per cent. in hospital practice corresponded to a mortality of 10 per cent. in private practice.

Dr. E. W. Mitchell, Cincinnati, Ohio, fully believes in toxins from the pneumococcus. From his observation of the disease in the hospital he has come to hold the view that acute pneumonia is an infection and not an inflammation; that the essential factor in the pathology is not the mechanical one, but the toxin effects. We hope for the development of a better treatment with the aid of antitoxin. If the analogy is so close between diphtheria and pneumonia we should hope before long to have the antitoxin which shall be as efficacious as the diphtheria antitoxin. The comparison has already been made between the class of patients which come into the public hospitals, the old drunkards, with liver and kidneys in a degenerate condition, the heart fatty, and whom no drugs will be able to save, and private patients. It is remarkable that death statistics do not show much difference between the death-rate of pneumonia—which had a death-rate of 40 per cent. fifty years ago—and that of the present day with all the advances of modern therapeutics. About our only hope in therapeutics, therefore, appears to be in the serum treatment. According to the last speaker, the normal salt solution is of value in acute pneumonia, and this seems reasonable. The speaker has not much faith in any form of local application, but his own preference has been for the hot bath, and internally he uses digitalin and strychnin. He is not sure, however, that he has obtained as favorable results as Dr. Eichberg claimed in his paper. Our resident physicians in the hospital are acute observers. A few days ago, at his hospital, the residents reported that they had noticed that all the cases treated by the hot bath had died, while those who did not have the baths got well. In private practice he has obtained the most satisfactory results from the hot bath. He has also had very good results from the use of oxygen in pneumonia. He regards it as a valuable heart stimulant. The most valuable part of the treatment is fresh air, and he said that he would take out the side of the house or drag the patient's bed into the open air if possible or necessary.

IRRIGATION OF THE COLON AS A THERAPEUTIC MEASURE.*

GEO. J. LOCHBOEHLER, Ph.D., M.D.
Assistant Professor of Materia Medica and Therapeutics and Lecturer on Pharmacy, School of Medicine, Georgetown University.
WASHINGTON, D. C.

The introduction of water into the bowel per anum is made by injection and irrigation. In the former, only a small amount of fluid is required; in the latter, the quantity is indefinite, as it is immediately allowed to again leave the system. The fluid acts in part mechanically as a foreign substance, provokes expulsion movements, as a solvent for intestinal catarrhal products, and, where large quantities are used, drags upon the upper intestinal coils, causing thermal changes and peristalsis.

These large quantities are introduced by means of the rectal tube, made of soft rubber, preferably with the opening at the end, to prevent clogging by fecal masses, as often occurs where the tube opens on the side. An ordinary fountain syringe is attached to the tube and the flow and pressure of the fluid is readily controlled by constricting the tubing. It sometimes happens that the tube coils upon itself when it enters the sigmoid flexure and the liquid is prevented from passing farther into the bowel. Turck,[1] of Chicago, has devised a special form of tube to obviate this. From two to four quarts of water are required, the temperature of which varies according to the nature of the case in hand.

---

[*] Presented to the Section on Materia Medica, Therapeutics and Pharmacy at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

As these irrigations act mechanically in that the weight of the fluid draws upon the upper portion of the intestines, they are often of great value to relieve constrictions and incarcerated hernia, to remove fecal matter, mucus and epithelial remnants in chronic enteric catarrh, in dysentery, and in oxyuria, in fact, in all conditions where the system has been depleted or become vitiated by toxic autoinfection, such as hemorrhage, cholera, yellow fever, diabetes, uremia, shock, collapse, etc. In these cases the normal saline solution has been given with the best results, as seen by the improvement in the circulation, the re-establishment of the normal temperature of the body and the stimulating effect upon the nervous system.

Irrigation of the colon has been followed by immediate amelioration of the serious symptoms of the initial stages of appendicitis, and Love[2] reports several cases in which enemata of one-half gallon of water at 100 F., mixed with soap, were given high up, producing peristalsis and flushing out the irritating matters of undigested food, ptomains, etc.

Shuell[3] recommends the same treatment in typhoid fever, "to remove at as early date as possible all ptomains and decomposing substances from the colon." The fluid may be readily made to pass the sigmoid flexure and reach to, or near, the cecum. The injection will distend the bowel and remove the accretions from the sacculi. He also cautions against its use during the stage of necrosis of the glandular tissue, as the solitary glands of the large intestine are affected in a large proportion of cases.

Hensell[4] speaks of the value of colonic irrigations of one-half to one liter, twice a day, reaching up to the ileum, so that their effects are also directly upon the gall-bladder and liver; and Löwenthal[5] reports forty-one cases of catarrhal jaundice cured by this method. These cases were of the type of gastroduodenal catarrh, with symptoms of anorexia, pressure in the gastric and hepatic regions, constipation and great prostration.

AUTHOR'S CASES.

Case 1.—Typhoid fever; female, aged 20 years. When first seen, on the eleventh day of the disease, she presented every characteristic symptom, except the diazo-reaction, which was absent throughout. From the fourteenth to the twenty-fifth day her evening temperature ranged from 103 to 105 F., which was promptly reduced to 100 by cold spongings. On the evening of the sixteenth day she had a profuse hemorrhage from the bowels, and on the day following several smaller ones. Severe tympanites developed. At this stage irrigation of one-half gallon of water at 40 F., mixed with soap-suds and one-half ounce of turpentine, was resorted to, and after this was evacuated, one pint of normal salt solution was injected and allowed to remain. The ice pack was applied to the abdomen. After each irrigation marked improvement took place. The temperature fell several degrees, the pulse, which was from 140 to 150, and dicrotic, became strong, regular and reduced to 120 to 125 per minute, the nervousness abated, tremor and subsultus tendinum subsided. This treatment was continued until the twenty-fifth day, when defervescence set in and the patient progressed to complete recovery.

Case 2.—Appendicitis; male, aged 45 years. Patient had just arrived from New York City, where he had a similar attack, which kept him in bed for five days. Having recovered, he attended to his business affairs and then started back to this city, but was seized on the train. When seen he was suffering very acutely, knees drawn up, anxious countenance, clammy sweat, temperature 100 F., pulse 90; exquisite tenderness over McBurney's point and continuous vomiting. Several small doses—¼ grain—of calomel were given, followed by a Seidlitz powder, ice to abdomen and high irrigation of the bowel with one-half gallon of water and soap at 40 F. After the intestinal tract was thoroughly cleared out by two more similar injections, at intervals of twelve hours each, the pain ceased, temperature and pulse became normal, and all further symptoms disappeared. The patient was under observation for three months after the attack and has since been in perfect health.

Case 3.—Appendicitis; male, aged 40 years. Was suddenly taken with violent pain in abdomen, especially pronounced over McBurney's point. Temperature 99.8 F., pulse 90. He presented all the symptoms of Case 2, but was seen several hours earlier in the attack. The same treatment was given and he recovered completely, and has been well since.

In each of the above cases surgical interference was considered; in the first case for impending perforation, in the latter, for the most opportune time to operate, but each improved at the most critical stage, which can only be attributed to the free irrigation of the colon.

DISCUSSION.

Dr. Daniel R. Brower, Chicago, said that too little attention has been given by the profession to colonic flushing. He, personally, very much prefers the normal saline solution to soap and water, or anything else which has been proposed for this purpose. The solution should be about the temperature of the intestinal tract. Not only does this flushing have a very great effect on the contents of the colon, but there is also a very prompt and remarkably active effect on the renal organs. In cases where the kidneys are deficient, as in certain infectious diseases, a large amount of saline solution thrown into the bowels will very speedily set up action of the kidneys. It is diuretic as well as antiseptic in its relation to the colon, and this feature is often overlooked. He is quite sure that this therapeutic measure is not resorted to as often as it should be.

Dr. O. T. Osborne, New Haven, Conn., approved of the recommendation of colonic flushing and said that it is not resorted to as often as it should be by surgeons after operations. Some make it a routine practice to inject 1 to 2 quarts of saline solution, but many others do not. The condition of surgical shock is due to paralysis of the vasomotor system, and in that condition the heart gets very weak, because the ventricles are not properly filled. The moment the blood-tension goes down, that moment the heart is impaired in its action. Flushing the colon fills the blood-vessels at a time when we know it will take several hours before anything can be absorbed from the stomach owing to nausea and vomiting, also during this period very concentrated urine is passed. This condition threatens kidney congestion and will be overcome by colonic flushing with normal salt solution.

Dr. J. C. Culbertson, Cincinnati, Ohio, said that as a means of reducing temperature, flushing of the colon with cold water, in infectious diseases, is one of our best remedial expedients. A quart of ordinary ice water will reduce the temperature 1.5 degrees in a case of fever—say 103 F.—if thrown into the rectum and retained there, and it can be repeated as often as thought necessary. It is a very valuable resource, it can do no possible harm and is a source of comfort to the patient.

Dr. M. Bernheim, Philadelphia, said that in the paper read yesterday he had shown, by physiologic experiment, that following an injection of the salt solution there is an antiperistaltic action set up which carries the solution up into the higher part of the small intestine and also into the stomach. Therefore the beneficial action of the large injections of saline solution is more easily understood, as the surface for absorption becomes larger.

Dr. G. J. Lochboehler said that as regards temperature the use of ice water is often very beneficial, but in both of these cases he has used the injection at 40 F, which is sufficient to reduce temperature. He wished to call attention to the fact that the injection of ice water in the case of hemorrhage reported, with a temperature of 105 F., and about to die, was done as the best method of causing reaction, and he firmly believes that the patient was saved by checking the hemorrhage by the stimulating effect of the injection of cold water. But, as he already mentioned, the saline solution given at the body temperature will aid in a great many cases in aborting infection and infectious disease.

A PROTEST AGAINST THE USE OF PROPRIETARY REMEDIES.[*]

DANIEL R. BROWER, A.M., M.D., LL.D.
CHICAGO.

The profession is being overwhelmed by proprietary remedies. The manufacturers who project them copyright the name by which they are to be known, patent the process by which they are made, and patent the resulting product, so that these remedies must remain a monopoly for all time. Coblentz, in his recent edition of "Newer Remedies," gives a succinct account of about two thousand, all introduced during the last few years, and Lehn and Fink, in "Progress in Pharmacy and Therapeutics," enumerate about five hundred more.

I have recently had three of the leading dispensing druggists of Chicago, Messrs. Gale & Blocki, Dale & Sempill, and D. R. Dyche & Co., examine the last 1000 prescriptions on their files for the purpose of ascertaining how many of them contained these proprietary remedies, with the result that one firm finds about 20 per cent., another 21 per cent., and the third 26 per cent.

The most of these products are made in German color factories, as by-products; they are covered with this triple system of patents, and sold at an enormous profit in this country—I am told three or four times the price charged elsewhere. The therapeutic use of most of them is based on *ex parte* evidence; they are presented to us by expert promoters, with an abundance of literature, in which the effort is made to demonstrate that they are a positive cure for this or for that. The enormous production of these articles, and their extensive consumption, show a deplorable state of therapeutic morals, and the time has come, in my opinion, to protest against them.

These enterprising manufacturers and their accomplished agents, of course, have no use for the Code of Ethics and the traditions of the profession from the time of Hippocrates until to-day.

The Code of Ethics, Section 5, reads as follows:

> SECTION 5.—Equally derogatory to professional character is it for a physician to hold a patent for any surgical instrument or medicine, or to dispense a secret *nostrum*, whether it be the composition or exclusive property of himself or others. For, if such a nostrum be of real efficacy, any concealment regarding it is inconsistent with beneficence and professional liberality; and if mystery alone give it value and importance, such craft implies either disgraceful ignorance or fraudulent avarice. It is also reprehensible for physicians to give certificates attesting the efficacy of patent or secret medicines, or in any way to promote the use of them.

Notwithstanding the objections of these people and some of the profession, it must be that the great majority of our craft are in full and unreserved sympathy with these declarations of the Code, and therefore unite with me in this protest, and beg a cessation of this wholesale use of these drugs that are so expensive to our clients, and have not been subjected to sufficient clinical observation or pharmacological experimentation as to justify their scientific use.

Even if the remedies may have been determined to be meritorious by exhaustive scientific examinations, so long as the name is copyrighted, the process of manufacture patented, and the resulting product patented, we are perpetually at the mercy of monopolists who may fix the price and vary the composition or purity as fancy may dictate.

I see no objection on the part of a manufacturing chemist patenting a process. This is probably his right, and at best is but a limited affair, but when you add the other attachments you perpetuate it as a monopoly, to the great injury of scientific medicine, and to the detriment of our clients.

In the name of scientific pharmacy and rational therapeutics, I most earnestly protest against the present tendencies. We certainly have in our armamentarium enough well-tried remedies that have been subjected to thoroughly unbiased and carefully conducted physiological tests, and have had the ordeal of scientific clinical application, to enable us to fulfill the mission intrusted to us.

The national formulary has been of much aid to us; instead of prescribing "bromidia," we can at one-third the expense order liquor chloralis et potassii bromidi compositus; instead of "arsenauro," we can prescribe liquor auri et arsenii bromidi, and instead of antikamnia we can order pulvis acetanilidi compositus, and so with numerous other of these proprietary articles.

In conclusion, may I express the hope that this Section of the ASSOCIATION may call its members back to a more conservative prescribing, and issue its protest against the impetuous rushing after new and untried remedies. And, furthermore, that this great ASSOCIATION may use its mighty power to have our patent laws so modified that the present system of triple patenting of products made for the healing of the people may no longer be possible.

DISCUSSION.

DR. N. S. DAVIS, JR., Chicago, said that the lecturer had brought before the Section a subject which was of great interest, but especially so at the present time, because the Pharmacopeia is now in the hands of the revision committee. Two classes of proprietary remedies have been mentioned: 1. those combinations of drugs which are put on the market by their proprietors by skilful advertising, and 2, all those definite chemical products whose mode of manufacture is patented. As medical men, we must necessarily object to the patenting of articles which must be used for the benefit of the sick. At the present time many medicines are furnished to the medical profession which are not mixtures, but definite chemical compounds made by patented chemical processes. They are articles which the pharmacist could not duplicate were he called on to do so. These preparations are extensively used. Many of them have valuable medicinal properties. They will not be discarded by the profession because they have such properties. He would, however, discourage the use of mixtures, pills and tablets which are ready-made. We should adapt our prescription to the needs of the individual case, and this can not be done if we use ready-made mixtures or pills. He therefore agreed with the lecturer in his opposition to such protected pharmaceutical compounds, but, at the same time, he thought that we must continue to use some things which are covered by patent.

DR. J. M. ALLEN, Liberty, Mo., said that the paper of Dr. Brower directed attention very pointedly to one fact, viz., that the use of this class of remedies is becoming very general all over the country. The effects of the use of ready-made pharmaceutical compounds by physicians would be: 1, to lessen their study of materia medica and pharmacy; 2, to lead in the direction of routinism, thereby arresting growth and investigation. He had never used a formula in his life and always advises his students never to use them, but to study carefully materia medica and pharmacy, then formulate their prescriptions as a force to combat the etiologic and pathologic forces of disease. If the physician will do this, he can have his prescriptions filled as accurately and elegantly in almost every little town in the country, as the so-called manufacturer of drugs can do it. He does not believe that it is wise or beneficial to the physician to dispense his own drugs. His time is too valuable. Besides, the pharmacists of the country are now educated gentlemen. He should send his prescription to a druggist as a distinct department in the practice of medicine. The physician should place himself in close communication with a pharmacist so that they will be of mutual assistance to each other. He has derived great benefit from this close relation, always finding them ready to render any assistance asked.

---

[*] Presented to the Section on Materia Medica, Pharmacy and Therapeutics, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

DR. A. BERNHEIM, Philadelphia, said that he had no connection with any manufacturing pharmaceutical business. He merely spoke to correct the statement that the cost of many medicines is much greater in this country than in Europe. For instance, antipyrin costs 5 to 6 marks per ounce in Germany, which is more than it sells for in this country. Moreover, these products are not recommended indiscriminately for everything, but they are carefully tested by clinicians, the most celebrated doctors in Germany, and only if they have been found to be very good are they put on the market. Of antipyrin he has frequently given and himself taken thirty grains, but he would not take ten grains of acetanilid. Of the names mentioned by the reader of the paper, antipyrin is also known as phenazon, an abbreviation of phenyldimethyl-pyrazolon, tannoform is only improved tannin preparation. We should not condemn patented articles as a class. The term "patent" comes from the Latin word which means "open," it is not concealed. It is very different with the class of pharmaceuticals of unknown composition where you never know what is in the compound, or what it will do. He personally had never prescribed any compressed tablet or proprietary secret medicine.

DR. A. B. LYONS, Detroit, Mich., agreed with all that he had heard of the paper. In regard to pharmaceutical compounds and patented drugs, he said that there is no unmixed evil in the world, and in attempting to eradicate some evil we should be careful that we do not take away something good with it. This is exemplified in the subject discussed in the paper. We associate the name of patent with things which should not be patented, and could not be. If an article had no novelty it could not be patented. He is heartily in favor of patenting preparations or discoveries by scientific men, if they could be, because the knowledge would thus be given to the world and it would increase the resources of science. He is, on the contrary, opposed to proprietary pharmaceutical compounds. If a man puts together two or three articles well known to the profession, on what ground can he claim the exclusive right to manufacture the combination? "None genuine without Smith's signature" means quackery every time in pharmacy. He was very much pleased with the remarks of Dr. Allen about students and the relation of pharmacists to the medical profession, and the overwhelming of the profession by commercialism. There are two classes of men who are now especially interested in selling medicines; the question is which class will physicians encourage, those who offer only a few remedies which they alone can supply, or those who aim to carry out the personal wishes of the physician in the preparations prescribed and deal in all medicines, and who seek to preserve the pharmaceutical profession.

DR. G. J. LOCHBOEHLER, Washington, D. C., said that we ought not to use prepared remedies, for in a great many cases they are not what they claim to be. Take, for instance, the emulsion of cod-liver oil. Professor Wiley, two years ago, analyzed all the emulsions in the market. Most of these are claimed to contain 50 per cent. of oil. Dr. Wiley found that, of all the samples, only three contained 50 per cent., most of them containing only 15 per cent., some only 3 per cent., and several none at all. There is a firm that puts up a preparation of cod-liver oil whose agent tells you that it contains everything that cod-liver oil should possess except the fat. It is free from the taste of cod-liver oil because it has *no cod-liver oil* in it. The taste of cod-liver oil can not be eliminated. But why use it? Why not use butter, cream and the fats of the daily food? Why not use the well-known remedies of the pharmacopeia instead of prescribing new, and possibly dangerous, compounds? A child went into a drug store and complained of headache; the druggist gave her five grains of antipyrin and she died in ten minutes. The coroner decided that the child died with cerebrospinal meningitis.

DR. TOMPKINS condemned the presumption of faith-curists and the practice of medicine by so-called ministers, who assume to know more about medicine than physicians. He mentioned a case of a young woman dying of consumption, who was taken out of the hands of the doctors by a bishop. but she died just the same.

DR. FRANK WOODBURY, Philadelphia, suggested that the manufacturing pharmacists of the present day are better business men than those of the early part of the century, and that if quinin, morphin and strychnin and similar indispensable drugs had not been discovered until the present time they would undoubtedly be patented. so that we must expect that hereafter all new drugs would be introduced in this shape. The fact that a drug is manufactured according to a protected process, therefore, should not prevent its use. He would, however, urge that the well-known drugs should not be hastily laid aside in favor of new and expensive substitutes. Too great eagerness for new and comparatively untried drugs inspires mistrust on the part of the patient, and may engender a suspicion that he is being used for experiment. There is no doubt that the taking up of new remedies is often due to ignorance of the value of the old ones.

DR. LYONS said that each particular subject must be studied on its merits and by some competent authority. Reliable evidence is needed as to what each special article will do. It is necessary that some board be constituted which shall exercise a censorship over this whole class of remedies, and this board should have behind it the authority of the AMERICAN MEDICAL ASSOCIATION.

DR. D. R. BROWER said that a very pleasant gentleman came to his office recently and showed him a pharmaceutical compound and told him what it would do. From his office the gentleman evidently visited other physicians in the same building that afternoon. On the next day the speaker entered the drug store in the same building and inquired whether there had been any prescriptions for this compound, and found that six had prescribed it within twenty-four hours after the promoter had visited them, and perhaps there were more prescriptions taken to other drug stores. This is a great evil. The same compound is also sold directly to the public; its uses are printed on the label where the public can see it. So that prescribing such remedies encourages counter prescribing and self-treatment. With regard to antipyrin, it may be cheaper here than in Europe, but he doubted it. He knew that people living in Detroit have gone across to Canada to get their prescriptions for antipyrin filled because it is much cheaper there. These new remedies are being constantly forced upon the profession; there have been some 2500 brought out within recent years. The question is, what shall we do in the matter? It is a very important question for the profession to answer.

CULTIVATION OF THE ESTIVO-AUTUMNAL MALARIAL PARASITE IN THE MOSQUITO —ANOPHELES QUADRIMACULATA.*

ALBERT WOLDERT, M.D.
PHILADELPHIA.

To determine this question my observations were carried on through the past winter and summer, the latter of which has been the warmest for thirty years. Previous to June, 1900, I had not discovered any specimens of anopheles here or in New Jersey, and but one specimen had been sent to me from Texas. In the previous fall I had treated a case of malarial fever in whose blood both crescents and ovoid bodies were found, which undoubtedly originated in Philadelphia,[1] and it was near this locality that my first efforts were made to capture adult anopheles or their larvæ. Periodic trips were made to this section during many weeks without avail, and I brought back only the larvæ of culex, chironomus and various other unknown larvæ.

About three-fourths of a mile distant from the house in which the case of fever had been treated, and near the League Island Navy Yard, on June 19, 1900, I managed to catch a small dark-brown or black and striped mosquito larva which agreed tolerably well with the description of Ross, in that "it lay upon the surface of the water like a stick and when disturbed would move off with a backward skating motion." Howard had subsequently[2] described the larvæ of anopheles as being "darker" than culex. Placing these larvæ, together with a small amount of algæ or green moss, in a glass jar, I succeeded in raising several to adult insects, which proved to be specimens of both anopheles quadrimaculata and anopheles punctipennis. Both of these species had therefore been caught in the same narrow and slowly flowing stream of fresh water which drained a marshy district formed by a railroad embankment.

---

* A paper read and specimen presented—by invitation—before the College of Physicians of Philadelphia, Dec. 5, 1900.

After this I made periodic visits to this section from June 19 till Nov. 11, 1900, and never failed to catch anopheles larvæ, except on the last trip, when they had disappeared, probably on account of the cold weather. In this way I have raised upward of 200 adult anopheles from the larvæ, some of which have been kept as long as twenty-seven days.

Subsequently, making journeys to regions where cases of malarial fever had developed, I discovered that anopheles could nearly always (all but one) be found in or near the infected houses. In this way I have been able to locate five localities within the city limits of Philadelphia where anopheles have their breeding-grounds.

This, in a measure, confirms the observations of others that "where there is malarial fever, there are mosquitoes." But it does not necessarily follow that where there are mosquitoes there are cases of malarial fever. Anopheles will always remain uninfected unless some vertebrate animal suffering with the disease comes among them. I have been informed that no autochthonous case of malarial fever has developed at the League Island Navy Yard for years, though there is a breeding-ground of the anopheles near by. On Sept. 10, 1900, I caught some larvæ of anopheles in a clear pool of water in the Pocono Mountains of Pennsylvania, a notable health resort, and at an elevation of nearly 3000 feet above sea level. The adult insects in this region are doubtless not infected, simply because no case of malarial fever has been brought near them. Five miles north of this locality—Tobyhanna—malarial fever has been found and another breeding-ground may be expected to be found there.

The malarial parasite of man may be classified into a natural order (Gymnosporidia), a class (Sporozoa), into different genera (Hæmamœba and Laverania), into different species (hæmamœba malariæ, quartan; hæmamœba vivax, tertian, and hæmomenas præcox, remittent fever—Ross); and it has been further proved that the flagellated malarial parasites are of different sexes.

Two of the interesting questions at present attracting attention is, How does the human malarial parasite keep up its cycle of existence, and how does it gain admittance into the blood of man? Its survival of the winter may be explained by the well-known fact that the tendency of this disease is to relapse, sometimes years after supposed recovery. In this way a patient supposedly cured of malarial fever by insufficient doses of quinin taken during the previous fall, has a relapse the following spring, and he in turn becomes the medium by which the disease is distributed.

As to how the parasite gains admission into the blood, if one theoretically holds to the belief that the spores of malarial fever breed in swamps or marshy districts and that the "miasm" is taken into the system through the respiratory tract, it necessarily implies that the spores or miasm must first have developed in some intermediate host, that they pass out of this host to become dried, and that they are blown through the air to the respiratory mucous membrane. According to Ross,[3] it is not the parasite itself which springs from the marshy ground, but the carrier of the parasite. On the other hand, if one theoretically holds to the belief that malarial fever may be contracted through the medium of drinking water, it necessarily implies that the spores of the disease, or whatever it is, pass out of the intermediate host into the water, and that the infective material remains alive in this medium though exposed to continuous changing conditions, or that the intermediate host contained in the drinking water is taken into the stomach through the medium of the food or drink. Lastly, if one holds to the belief, which has been confirmed by proof, that malarial fever may be contracted through the bite of the mosquito, he should state how such a condition may or does occur.

The question of preventive measures depends on a proper conception of its exact etiology. Marchiafava and Bignami[4] have studied the complete biological cycle in all the different species of human malarial parasites and have succeeded in inoculating four individuals with malarial fever who voluntarily submitted themselves to such investigation. They have been led to the following conclusions: MacCallum, while watching a flagellated malarial parasite (gametocyte), observed that after a time a flagellum became detached from the parent body and made straight for another parasitic body, which it entered, thus causing impregnation. From this phenomenon it is believed that flagellated parasites are of different sexes. Adopting the zoological nomenclature to simplify matters, one finds that mature sexual elements are spoken of as gametes (such as the crescent of the estivo-autumnal and its homologues of the tertian and quartan parasites). The female elements are known as macrogametes; the cells producing male elements are called microgametocytes, and the male elements themselves, microgametes. During certain periods of development of the estivo-autumnal parasite and its homologues in the other species of malarial parasites, if the blood be withdrawn from the circulation and left standing on the stage of the microscope for a period of from fifteen to twenty minutes, certain of the crescentic bodies change into ovoids, some of which subsequently become converted into flagellated parasites. From the latter forms free flagella (microgametes) tear themselves loose and penetrate certain other ovoid bodies which had not previously developed flagella. By this process fecundation of the female ovoid form (macrogamete) occurs, after which it rapidly develops flagella and by means of its sharp extremities has the power of penetrating dense muscular tissue such as the middle intestine (stomach) of the mosquito, and on doing so, after a day or two becomes converted into the zygote. Within the latter bodies the spores or sporozoites develop, and about the seventh day rupture into the celom or body cavity of the mosquito; thence they are carried to the salivary glands to be poured out the moment the insect bites.

After becoming more familiar with the literature on this subject, I next endeavored to find out if the anopheles quadrimaculata found around Philadelphia was susceptible to infection from the malarial parasite. At this time the A. claviger of India and Africa had not been identified as our A. quadrimaculata by Howard.[5] The following observations are recorded:

Observation 1.—December, 1889. Blood contained ovoids and crescents. After a trial lasting several hours a specimen of culex would not bite. This was my first failure, which was repeated two days later.

Observation 2.—July, 1900. An adult patient whose blood contained two groups of tertian parasites, was bitten by two anopheles quadrimaculatæ. One of these escaped, the other died and was not dissected.

Observation 3.—July 20, 1900. Blood showed a large number of tertian parasites—double tertian—which were afterward stained by eosin and methylene blue, and by carbol-thionin. After a trial lasting from 8 p. m. to 11 p. m. a specimen of anopheles punctipennis would not bite. A culex pungens caught in the room bit the patient and was kept at a temperature of about 84 for 7 days and dissected, but was found not to have been infected.

Observation 4.—July 27, 1900. Blood contained two groups of tertian parasites, some of which were almost full grown. The patient was bitten by two anopheles quadrimaculatæ, which were kept at a temperature ranging from 76 to 80 F., for 7 days; they were not infected.

Observation 5.—August 7, 1900. This man had been suffering with a double tertian infection and his blood contained a large number of malarial parasites. He was bitten by an anopheles quadrimaculata two hours before a chill, and by three others about half an hour to within a few minutes of the chill. The anopheles were kept at a temperature ranging from 84 to 88 F. The one which bit first died on the third day, and two of the others died on the fifth day. The last one was kept for seven days. All of them were dissected but contained no zygotes.

Observation 6.—August 29, 1900. Blood contained a large number of tertian parasites in different periods of development, some full grown, others very small. The patient was bitten by three anopheles quadrimaculatæ, one of which was afterward kept at a temperature ranging from 80 to 84 for four days. It was dissected, but showed no pigmented cells or zygotes.

Observation 7.—August 31, 1900. Blood contained two groups of tertian parasites. This patient was bitten by two of the same anopheles which had previously bitten Case 6. They were kept same as No. 6 and dissected on September 2, but contained no zygotes.

Observation 8.—Date September 24, 1900. Blood contained two distinct groups of tertian parasites, some of which were almost full-grown and others in the stage of segmentation. Two and a half hours previous to the chill patient was bitten by three anopheles quadrimaculatæ, which were kept at a temperature ranging from 76 to 80 F. One died on the fourth day; the others were kept for five days. All were dissected, but contained no pigmented cells or coccidia.

Observation 9.—October 31, 1900.—A case of double tertian, in whose blood at 5 p. m. a very large number of full-grown and very active parasites were found, was bitten at 8.30 p. m. by two anopheles quadrimaculatæ, which were kept at 80 to 84 F. One died on the third day, the other was kept for five days. Both were dissected, but contained no pigmented cells.

Observation 10.—October 27, 1900. Blood showed a few ovoids and crescents. Patient was bitten by two anopheles quadrimaculatæ, which were kept at a temperature ranging from 76 to 84 for three days and dissected. Two zygotes near each other and containing black pigment granules were found near the lower portion of the middle intestine of one mosquito.

I also made several trips to the houses where cases of malarial fever were being treated, and in every instance but one succeeded in catching anopheles quadrimaculatæ.

In this connection I must note that in many instances the patients explained to me that mosquitoes had not been troublesome, and some had not seen any at all. However, after searching through the house, anopheles were caught. This is easily explained, since patients have very frequently told me they could feel nothing, although at the time I could see the anopheles biting. These latter mosquitoes were afterward dissected, but contained no zygotes. Other anopheles were caught in barns in a district where a large number of cases of malarial fever had occurred, but none of these were infected.

In all of the cases here reported of malarial fever, parasites were found. Most of them were discovered in the fresh blood, but a large number were afterward stained, some with eosin and methylene blue, others with carbol-thionin, some with eosin and hematoxylin, and some by the Romanowsky method.

To recapitulate: Of 10 cases of malarial fever, 7 of them were bitten by 16 anopheles quadrimaculatæ and one by a specimen of culex, and in this series only one anopheles was infected (Case 10). I can only explain the cause of my failure to cultivate the zygotes in the majority of anopheles on the ground that but one of the cases probably contained the preflagellate forms of the malarial parasites at the time the anopheles bit (which confirms the results obtained by others), or else that the insects were not in a condition necessary for infection. (See note.)

The season was now drawing to a close, and after fourteen months of work, as good fortune would have it, the following interesting case, which is the last of the series, was very kindly placed at my disposal by Dr. Frederick A. Packard, visiting physician to the Pennsylvania Hospital of Philadelphia:

Observation 11.—The patient, white, aged 50, was admitted to the Pennsylvania Hospital, Oct. 31. 1900, suffering with estivo-autumnal malarial fever—H. præcox.

Examination of the Blood.—At 7:30 p.m., Nov. 1, 1900, a drop of blood was removed from the tip of the finger and was at once examined with a 1/12 oil-immersion lens (Leitz). Ovoids and crescentic malarial parasites (gamete-forms) were found, some of the latter being intracorpuscular and moving. Many of the ovoids contained a very large amount of reddish pigment, which for the most part was arranged around the periphery. In other ovoids from the center could be seen a small projection or rounded arm which moved outward toward the periphery. After about twenty minutes a flagellated malarial parasite was found. It was deeply pigmented and possessed about five long arms, which waved about quite rapidly. At the tip of one of these flagella there was a small particle of a red cell attached which was tossed around in all directions. Blood films were afterward selected and stained by eosin and methylene blue, by eosin and hematoxylin, by carbol-thionin, and by the Romanowsky method. They all showed ovoids and crescents. Following Manson's method, with some modifications, I succeeded in staining a flagellated malarial parasite by the Romanowsky method. Flagellated parasites appeared to be few in number, which may account for only one positive result. As soon as the flagellated parasite was discovered, a specimen of anopheles quadrimaculata was applied, which bit the patient. Six others subsequently bit. The mosquitoes, after biting, were kept in a warm locality for a period of probably one hour, and were afterward placed in a box and kept at an average temperature of 78 F. One of these anopheles was dissected on November 5 at 11 a.m.; it was not infected. Two others were dissected at 4 p.m., November 5; one was not infected, while another contained near the lower portion of the middle intestine 4 zygotes in different stages of development, which is characteristic of these bodies. (See plate.) Another was dissected November 7, and was not infected, while still another was kept thirteen days, but nothing was found. Two of the insects escaped.

While this anopheles probably only bit once, on Thursday at 8 to 9 p.m., and was dissected at 4 p.m. on the Monday following, the specimen of middle intestine evidently shows the zygotes of estivo-autumnal malarial fever in different stages of development; No. 1 is a very young form, resembling in contour and general appearances the ovoid body seen in the blood, while specimen No. 4 is of a later period of development. Specimen No. 2 resembles very much the crescent parasite of the fresh blood, thus evidently showing the powers of the zygote to preserve its original type.

The most distinguishing characteristics of the coccidia of this type of fever which serve as its means of identification are: 1, the presence of reddish pigment-granules similar in color but larger than that seen in the malarial parasite of the blood. The pigment, too, is arranged around the periphery of the zygote; 2, the zygote of this stage has a very thin and hyalin capsule around the periphery; and 3, the distinctness of this pigmented cell. By this means I was able to identify these bodies, though much assistance had been afforded me by a specimen of middle intestine infected with the zygotes of proteosoma Labbé and loaned through the kindness of Dr. Ronald Ross.

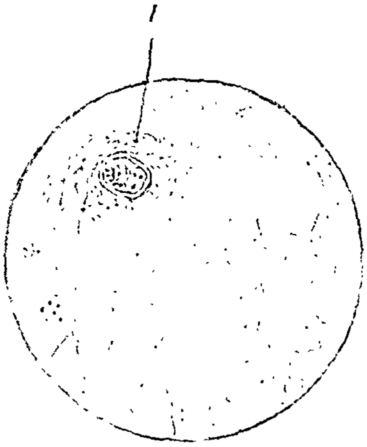

Fig. 1.—Ovoid-shaped zygote of an early stage of development about 8 to 10 microns in diameter, and containing numerous reddish pigment-granules and vacuoles.

*Nothing can be determined by a macroscopic examination of the infected middle intestine of the anopheles. It still possesses its light brownish tint. With a No. 3 ocular and No. 7 objective (Leitz) the zygotes Nos. 1, 2, 3 and 4 become quite clear and the reddish pigment dotlets have a brilliant tint. The rest of the body of the coccidia has a bright hyalin appearance, and in areas adjacent to the pigment a more or less granular appearance is observed. The general outline and finer characteristics of the coccidia are to be determined by a No. 3 ocular, and 1/12 oil-immersion lens.

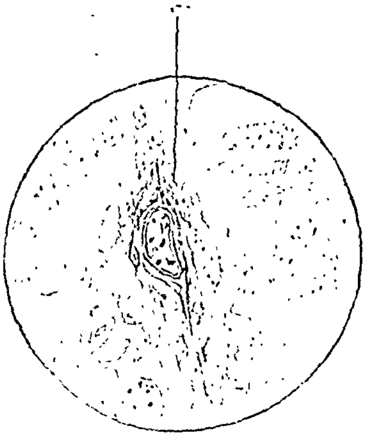

Fig. 2.—Crescent-shaped zygote, containing numerous reddish pigment-granules and pushing aside muscle fibers. Pigment-granules are of larger size than in No. 1, and pressed toward the periphery. About 7 microns in width, and 14 to 16 microns in length.

Zygote No. 1.—This coccidium has the general characteristics of the ovoid body of the estivo-autumnal parasite seen in the fresh blood, with the exception that in the zygote the pigment granules are slightly larger and appear to be pushed outward toward the periphery of the cell. That portion of the cell body in which no pigment is observed has the faintest yellowish tint. The zygote possesses a very thin and hyalin capsule. The entire body stands out prominently from the surrounding cells. This specimen is located in the lower portion of the middle intestine and is external to the epithelial cells. It is slightly larger—8-10 microns—than a red blood-cell.

Zygote No. 2.—While the former coccidium was situated outward and external to the epithelial cells, this specimen selected a position among the muscular tissues, which it presses to either side. In shape it corresponds to the crescent of the fresh blood. It has a faintly yellowish and hyalin tint and around the periphery the brilliant reddish pigment granules are disposed. The granules are fewer in number than in the crescent parasite and are larger, looking as though there might have been a coalescence of these particles of destroyed hemoglobin. A faint colorless area—vacuole—surrounds each pigment granule and a more or less elongated slit-like vacuole is seen in the center, but any attempt to draw these only exaggerates their appearance. A very delicate and hyalin capsule surrounds the coccidium. The entire body has a stamped-out appearance and is very distinct. It is probably 7 microns in width and 14 to 16 in length.

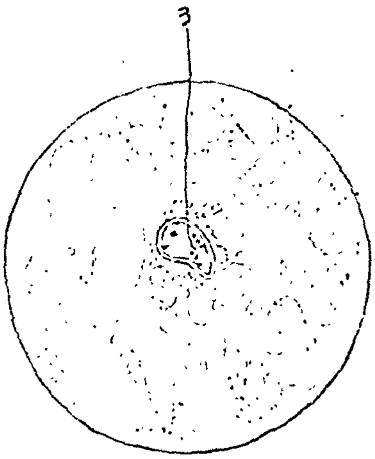

Fig. 3.—Vesicular-shaped zygote, containing bright reddish pigment-granules and slit-like vacuoles. The body of the coccidium has a faint yellowish tint. It is about 10 microns in diameter and 14 to 16 in length.

Zygote No. 3.—This coccidium is the lowermost of all, being located near the middle intestine, which gives origin to the Malpighian tubes. It has a more or less elongated crescent shape and is probably of a somewhat later stage of development than the former two coccidia. It is situated external to the epithelial cells, and is adjacent to a spiracle—same a-

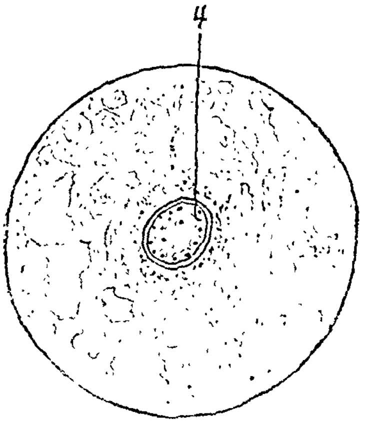

Fig. 4.—More or less ovoid-shaped coccidium, containing numerous reddish pigment-granules, which are distributed around the periphery. Numerous slit-like vacuoles are shown. Zygote about 12 to 14 microns in diameter, and 16 to 20 in length.

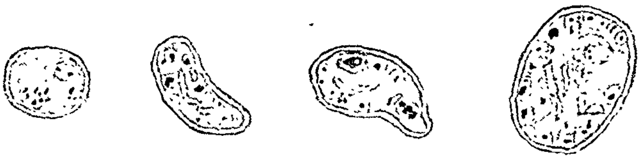

Description: Four zygotes (unstained) of estivo-autumnal malarial parasite (observation xi) in different stages of development, and found in lower portion of middle intestine of anopheles quadrimaculata (or claviger). No. 3 ocular and 1-12 oil-immersion lens (Leitz). The mosquito bit on Thursday, 8-9 p. m., and was dissected on the following Monday at 4 p. m. (November 5, 1900).

No. 1. This zygote also contains reddish pigment granules, some of which are two or three times as large as those seen in No. 1. Faint vacuoles surround each pigment granule and a few slit-like vacuoles are contained in the body of the coccidium. The central area has the slightest yellowish tint. Its outline is sharply defined on account of the hyalin capsule which surrounds it. This zygote is about 10 microns in width, and 14 to 16 microns in length.

Zygote No. 4.—This coccidium has a flattened and ovoid shape, and is the largest of all. It can be readily studied with a 1/7 in. objective. It is also located in the region of the Malpighian tubes and is somewhat external to the deeper epithelial cells. It has a faint hyalin capsule, and bright reddish pigment granules of different sizes and shapes are disposed around the periphery of the body. Some of these are three or four times the size of the pigment granules of the H. præcox of the fresh blood. Certain portions of the inner lining of this coccidium have a more or less thickened appearance, and toward the center a few slit-like vacuoles are observed. Faint vacuoles surround each pigment granule. The central area of this zygote has a faint yellowish tint though the general appearance as in all the others is hyalin. It has a stamped-out appearance and is very distinct. All these characteristics are brought out by focusing up and down. In length this coccidium is probably two and a half times the diameter of a red blood-cell —16 to 20 microns—and is probably 12 to 14 microns in diameter. The general characteristics of the zygotes are best studied with the iris diaphragm about one-half open.

I wish to tender sincere thanks first to Dr. Frederick A. Packard for his kindness in placing this case for study at my disposal; next to Prof. Simon Flexner, of the University of Pennsylvania, who has placed at my service the facilities of his private laboratory for research work; and to the following named, who have given me the opportunity of studying cases of malarial fever, namely: Drs. J. C. Wilson, W. C. Hollopeter, M. T. Prendergast, J. M. Cruice, N. D. Pontius, Frank White, Julius Salinger, A. P. Francine, and George W. Norris; and to the Sisters of St. Joseph's Hospital for favors. To Dr. Ronald Ross I am greatly indebted for an examination of one of his specimens, and for his literature, which has been invaluable in identifying the coccidia herewith presented, and to your president, Dr. W. W. Keen, I must thank for his kind invitation to speak to you this evening.

This specimen presented is, I believe, the second one reported in America, the first one having been made by Dr. W. S. Thayer.

Note: After submitting this article for publication I read —Report of the Malaria Expedition to Africa, Liverpool School Tropical Medicine, Memoir No. 2, 1900; Ross, *Annett*, Austen, Giles, and Fielding-Ould—that in order for the zygotes to develop, the insects must as a rule first have obtained a meal of blood or must first have been fertilized. *In my first few observations* the anopheles were raised from larvæ, while in the last two instances adult mosquitoes were used.

1706 North Sixteenth Street.

Xanthoma Multiplex.—Dr. William Osler recently exhibited, at his public clinic, two cases of that rare affection, xanthoma multiplex, *the first* observed at the hospital. Both were in women, aged 30, and both had jaundice, one of ten and the other of two years' standing. Each had suffered from recurrent attacks of pain, vomiting, chill, fever and sweats, followed by increase of jaundice. There was not much loss of flesh.

AN ORIGINAL CHART OF THE NEURONIC ARCHITECTURE OF THE VISUAL APPARATUS.

WITH EXPLANATION.

LOUIS STRICKER, M.D.
CINCINNATI, OHIO.

Having been deeply impressed by the study of the recent work of Dr. St. Bernheim, of Vienna, on "The Nuclear Origin of the Ocular Nerves and Their Connection With the Cortex of the Brain,"[1] and no comprehensive diagram being appended from which a general conception of this intricate mechanism could be gleaned, the idea was conceived of preparing a chart which would retain as far as possible anatomic relations, and at the same time bring graphically before the eye the neuronic architecture of the visual apparatus. In so doing Bernheim's text has been strictly adhered to. Bernheim's investigations extend over many years, and have been followed in various directions, namely by anatomic studies of the brains of young infants and embryoes, experiments on animals, biologic studies, the study of pathologic conditions in man, both clinically and subsequently on the anatomic specimens, and these studies have been further confirmed by physiologic experiments on monkeys, and pathologic conditions induced and subsequently traced and studied. The nerve fibers were traced by the Weigert stain, whereas their origin and *final* endings have been disclosed by the Golgi stain. These methods have been supplemented by artificial and naturally produced degenerations according to the Marchi method and that of Nissl.

This chart represents an entire cross-section of the brain, made on a level with the optic thalami; the temporal and frontal lobes have been cut away, as also the cerebellum, thus exposing pons and medulla. The eyeballs, optic nerves, chiasm and optic tracts have been sketched, showing the manner in which the tracts embrace the peduncles and then turn upward and inward to distribute their fibers to the primary optic centers, *namely, the external* geniculate bodies, the optic thalami and the anterior corpora quadrigemina, where they split up into fine dendrites which are in apposition with dendrites given off by the large ganglion cells in these primary optic centers. In their turn these ganglion cells send out dendrons, which are distributed to the visual centers *in the cortex* of the occipital lobes, where conscious vision is aroused; others go to portions of the occipital lobes where not only vision is aroused by contact with cortical cells, but these cortical cells give off dendrons which run to the motor cortical areas—visual association fibers. From the motor cortical areas the cortical cells send long fibers through the peduncles under the floor of the third and fourth ventricle to the motor ocular nuclei of the opposite side, thus inducing *movements of the* eyeballs or, passing downward in the cord, lead to movements of the hand and foot. But there is also a more direct connection between the optic nerve and the motor ocular nerves. Some *of the* fibers which pass down the optic tracts pass directly to the centers for the sphincter of the pupil and accommodation, thus producing the *short reflex arc* and through means of which all the other motor ocular nerves, third and fourth, are brought into communication with the optic nerve. But the sixth nerve is far removed from these centers and this, as well as all the other cranial motor nerves, and even sensory impulses from without, are communicated by means of the posterior longitudinal bundle, which carries both centripetal and centrifugal fibers. Hence, the *motor* nerves of the eye can be aroused to action, 1, as a result of impulses derived from the motor areas of the cortex; 2, through the short reflex arc which exists between the optic nerve and the centers of the pupil and accommodation; 3, through the posterior longitudinal bundle, which connects not only the various motor nerves, but likewise carries sensory impulses from without, it being made up of both centripetal and centrifugal fibers.

---

[1] Graefe-Saemisch Handbuch d. gesamt. Augenheilkunde, 1900. II. 15 u. 16.

The Retina is essentially made up of three distinct neurons: 1, the rods and cones, which are stimulated into action by the chemical action of light on the visual purple; 2, an intermediary cell, and 3, the large ganglion cells, which send their fibers isolated and direct to the primary optic centers carrying centripetal impulses —a few *centrifugal fibers* have been traced from the various primary centers and some have been observed in the cortical areas, but so little is known regarding them that they will receive no further attention here.

All these fibers derived from the ganglionic cells converge to a common area, the disc, and here form bundles of fibers which, after passing through the lamina cribrosa take on their myelin sheaths, forming the optic nerve, which passes backward through the optic foramen to the optic chiasm, where a partial decussation of fibers takes place.

The decussation has been the subject of much discussion and investigation. Bernheim finally declares that the fibers located dorsally, that is, nearest the brain, are uncrossed, whereas those ventrally placed—nearest the bony base—are crossed fibers. In the optic nerve these fibers are differently placed, depending on the portion of the nerve examined. Close to the disc, crossed fibers are found in the median and temporal parts; uncrossed fibers are found above and below; the macular bundle occupies the temporal quadrant, being made up of crossed and uncrossed fibers. About the middle third of the optic nerve, the crossed fibers occupy a section from above and to the temporal side downward and inward; the macular bundle occupies a central position in the nerve. At the optic foramen, the crossed fibers occupy almost in a vertical line the median half, the uncrossed the temporal half. In the chiasm, the uncrossed are above, the crossed fibers below. In the optic tracts, the crossed and uncrossed fibers, peripheral and macular, are dispersed equally, and the bundle arrangement is entirely lost. At the disc the macular bundle lies to the temporal side; in the optic nerve it is centrally located, whereas in the chiasm it is wedge-shaped, crossed fibers below, uncrossed above and in the tract its fibers are thoroughly mixed with all the others.

The optic tracts diverge in a wide circle, pass under the peduncles of the brain and become flattened, and embrace the peduncles, pass upward and inward to be distributed to the primary optic centers. Where the tracts turn to bend upward a longitudinal furrow appears, which divides the tract into a median and a more lateral portion. The lateral portion of the tract is lost in the corpus geniculatum externum and the optic thalamus, whereas the median branch goes through the corpus geniculatum medial to the anterior corpora quadrigemina.

In the optic nerve are found only fibers which are intended for the visual act and those which produce pupilary reflexes. In the chiasm a bundle of fibers is found—persisting in degenerative processes—which has nothing to do with sight. These fibers run from the internal geniculate body of one side along the inner side of the tract, through the dorsal side of the chiasm, to occupy the same position in the opposite tract and internal geniculate body. Some of these fibers extend under the anterior corpora quadrigemina to the corpus Luysii, a small nucleus anterior to the nuclei of the third nerve and to either side of the optic thalami. This bundle of fibers is known as von Gudden's commissura, and its exact nature is unknown, as is also the use of the fibers which go to the corpus Luysii. Some few of the fibers extend into the posterior quadrigemina, and in this manner are brought into relation with the sense of hearing. Hannover's fibers, found partly at the anterior, partly at the posterior surface of the chiasm, are not in any way connected with the body of the chiasm. Meynert's fibers lie parallel to the posterior arc of the chiasm, are not incorporated in the nerve proper, and are not anatomically considered a part of the chiasm.

Bernheim states that in the chiasm some of the fibers split, one branch going to either side; likewise anastomoses take place; further, that fibers of different caliber exist, one to produce impressions of sight, the other to cause reaction of the pupils. Anatomically no difference exists between crossed and uncrossed fibers. In the tract the fibers are arranged regularly, one next to the other, until they reach the bend and the fibers ascend to reach the primary optic centers. Fully 70 per cent. of all the fibers enter the external geniculate body, and all the macular fibers are supposed to be included here. The external geniculate body is made up of alternate layers of white and gray substance. In the gray substance are found multipolar cells closely matted together, between which the fibrils, radiating fan-shaped, end. These fibrils are the true optic-nerve fibrils, both crossed and uncrossed, of practically equal proportions. Another set of fibrils pass around and under the edge of the external geniculate body and pass over on to the surface of the anterior corpora quadrigemina. Still others take a course backward and downward and then forward to get beneath the surface of the aqueduct of Sylvius. These are both crossed and uncrossed fibers and intended to produce the pupilary reflexes.

Of those fibers which enter the optic thalamus, the main body passes under the external geniculate body and into the pulvinar, and can be followed as far as the stratum zonal. Other fibers pass between the two geniculate bodies, especially around and through the geniculate body medial to the deep portions of the thalamus, ending in the pulvinar and designated as the deep thalamus fibers of the optic nerve in contradistinction to the superficial, which pass through the corpus geniculatum medial and anterior corpora quadrigemina. Bernheim asserts that no fibers end in the corpus geniculatum medial; hence this body has nothing to do with sight.

The Oculomotorius or Third Nerve.—Seated in the floor of the third ventricle occupying an area equal to and situated just beneath the anterior corpora quadrigemina, are the nuclear centers for the third nerve. In the drawing, owing to the impossibility of otherwise displaying the individual nuclei, this area has been greatly exaggerated. The entire mass of nuclei occupies the space to either side of the median raphe, and are arranged so as to form a concavity laterally to either side. In a frontal section, the edges would converge ventrally whereas they would diverge dorsally, and the posterior

DIAGRAMMATIC.

longitudinal bundle would occupy a space ventrally and laterally.

Strictly speaking, there are no distinct lines of demarcation between the various nuclei which supply the fibers for individual muscles. The nuclei gradually merge one into the other. Aside from the large motor ganglion cells, one finds numerous small round cells which are the intermediary link by means of which the motor ganglion cells of the nuclei are brought in contact. The same is true of the nuclei on opposite sides of the median raphe. The motor cells do not send commissural fibers across the median raphe, but contact of dendrons through the medium of the round cells has been established. The fact that some of the nuclei send their fibers, or a part, to the opposite side has given rise to the belief that a commissura existed.

Lying within the proximal end of the nuclear region are two nuclei made up of smaller ganglion cells than the other nuclei, and known as the small-celled nuclei, and identical with the Westphal-Edinger nuclei. Seated below this, occupying a central position, spindle-formed in shape, containing large ganglion cells, lies a single nucleus. It is sharply defined from the lateral nuclei, its dorsal edge lies within the limit of the lower edges of the two small-celled nuclei, whereas fine dendrites from the posterior longitudinal bundle just reach its ventral surfaces. These three groups of cells are particularly important in that they receive fibers coming direct from the optic tract, thus producing what has already been spoken of as *the short reflex arc.* This offers an explanation for the direct and the consensual reaction of the pupil and the accommodative act, also by this connection all the other motor-ocular nerves are influenced. The fibers derived from the nuclei in the anterior portion of the nuclear area go to the same side, those derived from the lower portion are nearly all crossed. All the fibers which cross to the opposite side converge toward the median line, dip down below the raphe, and rising up again on the opposite side, diverge fan-shaped, passing between the fibers of the posterior longitudinal bundle. The uncrossed fibers dip down with a slight concave curve on the same side, pass between the fibers of the posterior longitudinal bundle, and remain on the same side.

As a result of physiologic experiments and experimentally produced pathologic conditions, subsequently microscopically studied, regions have been mapped out, the fibers derived from which supply the nerves to definite muscles. The small-celled nuclei anteriorly placed supply the sphincter of the pupil, and the fibers go to the same side. The large-celled single spindle-shaped nucleus supplies the muscle of accommodation of both eyes, sending fibers to both sides. At the distal end is the center for the rectus inferior, the fibers passing to the opposite side.

Following in order lie the center for the obliquus inferior sending fibers to the opposite side, and from the ventral portion fibers go to the same side. The center for the rectus internus gives off fibers to the same side and from its dorsolateral portion fibers go to the opposite side. From the center of the rectus superior fibers go to the same side, and from the center of the levator fibers go to the same side.

The Trochlear or Fourth Nerve.—This lies in almost direct connection with the oculomotor. The fibers emerge from the lateral side of the nucleus, make a slight curve outward and downward close to the fibers of the posterior longitudinal bundle, and then on a level with the descending root of the trigeminus they pass upward again to a point on a level with the widening aqueduct of Sylvius. Here the fibers form several bundles and turn abruptly backward in the roof of the fourth ventricle, where they cross over to the opposite side and appear at a point close to the posterior part of the posterior corpora quadrigemina and embrace the lateral side of the peduncle as a compact nerve root.

The Abducens or Sixth Nerve.—This nerve takes its nuclear origin about the center of the floor of the fourth ventricle. The nuclei lie close to the median line and are separated from each other by the fibers of the posterior longitudinal bundle. Its nucleus lies in a hollow space, the result of the curve made by the fibers from the facial, which almost encircle it. The ganglion cells are multipolar and of the motor type. The fibers arising from this nucleus take a dorsal and median direction toward the floor of the fourth ventricle, joining together to form a more compact band to the median side of their nuclear origin. Making a distinct curve, they turn backward toward the ventral surface of the brain to make their exit in the pons to either side of the median raphe. The fibers of this nerve remain on the same side. From the ventral and lateral surface of the nucleus a few fibers extend to the small olivary body. These fibers are especially important in that they help to close the circuit between the acoustic and the sixth nerve.

The Facial.—The nuclear origin lies somewhat posteriorly and laterally from the abducens. All the fibers derived from this center extend upward and inward toward the median line, and then curve around toward the floor of the fourth ventricle, and in so doing cover the dorsal and lateral portions of the sixth nerve. The fibers then bend downward toward their origin to finally make their exit on the same side in the pons. Owing to the peculiar course which these fibers take, they are not only brought in close connection with their own nuclei, but with the abducens, which they almost encircle, with the posterior longitudinal fibers, and with the sensory root of the fifth nerve.

The facial sends branches to the orbicularis palpebrarum and the frontalis muscle. So far as known, the only manner in which these muscles are brought into simultaneous action with other eye muscles is through the medium of the posterior longitudinal bundle.

The Trigeminus.—The fifth nerve supplies the sensory nerve fibers to the eye. The fibers are derived from the first and second large branches derived from the Gasserian ganglion. The sensory nuclear origin consists of a large ascending sensory spinal root, which extends down almost to the first cervical nerve—Bernheim calls this a descending root—and a smaller descending root. The motor nuclear origin lies close to the motor nuclear origin of the fourth nerve.

The spinal sensory portion as it ascends is in relation with the nerve vestibuli, the ascending portion of the facial and the posterior longitudinal bundle.

The Acoustic.—The accessory nucleus or central ganglion of the cochlear branch of this nerve is brought in relation with the sixth nerve by means of the fibers which run toward the median raphe to reach the trapezoid body. The trapezoid body contains ganglion cells which send fibers to the small or upper olivary body —nucleus olivarius superior—which latter has fibers connecting it with the sixth nerve. Thus the acoustic nerve can be brought in direct relation with the sixth nerve, and then through the posterior longitudinal bundle with the other motor ocular nerves. This gives the anatomic explanation for the physiologic reflex phenomena of turning our eyes in the direction of a sound.

The Posterior Longitudinal Bundle.—This, derived from the anterior fundamental strand in the cord, gradually comes to occupy a dorsal position close to the median raphe, under the fourth ventricle and upward under the fissure of Sylvius. Its line of demarcation is never very sharply defined, since it gives off fibers to neighboring strands of fibers. It has been followed as far as the nuclear origin of the third nerve. It is the connecting band by means of which the various motor ocular nerves are brought in communication with each other and by means of which the various synchronous movements of the eye-balls are brought about. It contains both centripetal and centrifugal fibers. As we have seen, some of the optic-nerve fibers go directly to the nuclear origin of the fibers which produce the pupillary reflexes.

The Short Reflex Arc.—Through means of this, all the nuclear centers of the third and fourth nerves are brought in direct connection with the optic nerve. These are further connected with each other and other cranial sensory and motor nerves by means of the posterior longitudinal bundle.

The conditions of the sixth nerve are particularly interesting, especially its connection with the rectus internus, in the production of synchronous movements of the two eyes to the right or left. A portion of the fibers derived from the nuclear origin of the rectus internus go to the opposite side, and by means of the longitudinal bundle, the abducens on one side of the raphe is connected with the rectus internus of the same side, part of the fibers of which go to the opposite side. At the same time, from the nuclear origin of the rectus internus the dendrons transmit the impulse by contact to the opposite nucleus, thus giving the full impulse to produce the movement inward of the one eye, while the abducens turns the other eye outward.

Cortical Areas of Sight.—We have seen that fully 70 per cent. of the optic-nerve fibers, both crossed and uncrossed and containing all the macular fibers, end in the lateral geniculate body. The fibers derived from the ganglion cells in this body at the same time taking up the fibers derived from the thalamus and the anterior corpora quadrigemina make their exit to the lateral side of the lateral geniculate body and pass around the posterior end of the corpus striatum and the lamina semicircularis, descend along the posterior horn of the lateral ventricle as a massive tract, known as the fibers of Gratiolet, to reach the occipital lobes. The fibers derived from the external geniculate body pass to the cortical areas of the occipital lobes in the region of the calcarine fissure, lobus cuneus, lingualis, gyrus descendens and the occipitotemporal lobes. This is the exclusive area of conscious vision. The fibers derived from the centers located in the corpora quadrigemina anterior and the optic thalamus are distributed to the second and third occipital lobes, areas not only for visual perception, but the fibers here come in contact with cortical cells which send their dendrons into neighboring areas, especially those areas which control movements and conditions that stand in relation to sight. This is true especially of the synchronous movements of the eyeballs. Thus, disease located toward the median portion of the brain, in the occipital lobe, would lead to loss of vision, in one-half of the field—hemianopsia—whereas disease more laterally located in the occipital lobe, attacking association fibers, besides producing hemianopsia, would present to us clinically soul-blindness, alexia, optic aphasia.

The association fibers connect the visual centers with the motor centers and go particularly to the gyrus angularis, irritation of which produces movements of the eyes in the opposite direction. That is, irritation of the right angular gyrus causes the eyes to turn to left, up or down. From the motor areas the fibers pass down through the peduncles under the fissure of Sylvius to the nuclei of the motor ocular nerves of the opposite side—a point of great value in the diagnosis of ocular paralyses and their relation to cortical disease.

ADDRESS BEFORE THE NEW YORK STATE ASSEMBLY COMMITTEE ON PUBLIC HEALTH.

IN THE DISCUSSION OF THE BELL BILL ("CHRISTIAN SCIENCE BILL") PROHIBITING THE PRACTICE OF MEDICINE BY UNLICENSED PRACTITIONERS.*

ROBERT T. MORRIS, M.D.
NEW YORK CITY.

We have listened to a great deal of oratory to-day in favor of various peculiar methods for treating disease. Now let us get down to plain common sense for a little while, if we can.

I would first ask the honorable members of the Assembly, before giving consideration to the points I am to make, to read in the *New York Sun of January 27*, the article by Dr. Wm. Osler[1] on "Progress in Medicine During the Nineteenth Century." I would ask them to read in the same periodical of February 3, the article by Dr. W. W. Keen[2] on "Progress in Surgery." From such basis of information it will be easy to place a proper estimate upon the value of fanciful theories of practice which you are asked to license.

When a group of believers in some theory cry "persecution" and claim to have something new, they are certain to engage the human nature of that large part of the public which does not know of the hundreds of new books and carefully conducted experiments, which annually mark the real progress of the substantial regular medical profession.

Nothing that claims to be new is neglected by responsible physicians, engineers or manufacturers.

OSTEOPATHY.

First let us consider the osteopaths: They have described, this afternoon, methods of treatment which are recognized as of value by regular physicians, but have described them in a crude way and have used, for its effect, the captivating statement that they seek the cause for disease and then remove the disease. How this appeals to all of us! It is like the prop that any new religious cult chooses for bolstering up its tenets—the prop of fraternal love and of duty to others. It promptly engages popular attention.

So they tell us that they seek for the cause of disease and then remove it. It is like the story of the boy who caught a six-pound bass up by the big rock! If you don't believe it we will go up and show you the rock! . . .

The osteopaths must of necessity benefit many cases that are adapted to their methods of treatment and our objection to licensing them is that they are wishing to assume too great responsibilities on a small margin of medical education. They are trying to find an easy way into a profession which requires long and arduous study before its members are fitted to care for our fathers and mothers, brothers and sisters—a profession that requires students to pass the regents' examination before even beginning the study of medicine.

All that we ask of the osteopaths is that they pass the examination in the rudiments of medical knowledge which our state requires of physicians, and after that they may practice what they wish. The state, for the protection of its citizens, simply asks them to show that they are familiar with the first principles of medical knowledge. Their practice is in principle the practice of the movement cure and of massage, which are recognized as important when properly applied. Their claim for having something new is entirely discredited by students of the well-established movement cures. It is not the sins of commission that are so harmful as the sins of omission made by men who are crudely prepared for practice.

One of the osteopaths has told us this afternoon that they have treated more than half of our senators and representatives at Washington. I suspected as much. Charlatans first try their treatment on public men in order to use their names. Patent medicine men first try their drugs on clergymen who are trained to accept things on faith. Responsible physicians first try their theories on the dog. [Laughter.] Why this murmur of laughter? It is not a flippant statement; I am speaking the plainest sort of truth. The reputable physician does not tell the public of the public men he is treating. He does not tell of his cures "after others have failed," but he earnestly works for the benefit of the public. That is his ideal of life work. Do not think that physicians are trying to protect themselves in urging the passage of this bill. It is for you that we are at work. What difference would it make in my income if every bootblack were to practice medicine—not one dollar's worth.

---

* Delivered at the State Capital, Albany, N. Y., Feb. 6, 1901.

[1] Journal A. M. A., February 2, p. 327.

[2] Ibid., February 9, p. 383.

The osteopaths tell us that they have received recognition in several states. That is because responsible physicians have felt that it was beneath their dignity to enter into a contest with them, but the time has arrived when we must attend to the matter.

Two men have been brought here this afternoon, from a distance, to testify that they have been cured by osteopaths. How far would a responsible physician have to go to find two patients of his who had been cured? Every hour in the day he is engaged in relieving suffering, curing disease, and so successfully that he would not stoop to the necessity of asking his patients to come here to testify to the results of his work.

Physicians do make mistakes—but the better the education of the physician, the fewer mistakes he makes; therefore, do not admit into our ranks men who are unwilling to qualify themselves against making mistakes.

An advocate of the osteopaths, Mr. Burroughs, says that "any *law* which decides against the rights of a man to heal suffering interferes with the rights of American citizenship." That is another "catch phrase." Will the osteopaths relieve suffering any less if we require of them an education which the state requires of its physicians?

"CHRISTIAN SCIENCE."

First let me say that I do not accept the nomenclature of "Christian Science" as descriptive, because science is classified knowledge, and they do not classify their knowledge properly for presentation to the people of normal minds. The "Christian" part of the nomenclature I must leave for others to discuss.

I have in the hospital at present a patient who had cancer of a certain organ. The "Christian Scientists" began treatment of this patient at a time when the disease was easily curable by surgical operation, and they continued treatment until the disease had progressed to a point where a desperate operation was required in order to save her life. This is one specific instance of injury caused a trusting patient who did not deserve to suffer. . . .

The "Christian Scientists" tell us that no coercion is used in bringing patients to accept their treatment. How about the case of a dutiful child? As to the matter of coercion, let us consider it. A woman of high social standing, of delightful personality and lovely character, goes into homes where a pleasant face is welcomed and a kindly word is a solace. She uses no coercion, but, let me assure you that her *persuasion* is more effective than four coercive policemen with clubs!

Let me quote another specific case of maltreatment. A little girl suffering with favus or "milk-crust," living not far away from me, has been under treatment by "Christian Scientists" and has received no other treatment. Her hair is nearly gone and she has been the means of spreading infection. When she develops into a beautiful young woman, and is ready to take her graces into society, she will have about eight hairs pointing in different directions, and I fear will curse the people who with kind words and soft voices have brought her to this predicament.

These cases quoted are of specific injury to the individual. Let me cite another of menace to the public. In a boarding-house containing twenty people, one of the number, a school teacher, developed measles. She called a "Christian Scientist," who told her that she merely "had a *belief* in a fever," but that she was not really ill. She associated with the other nineteen people at the table. A chambermaid made the diagnosis of measles and informed the other people in the house, but the "Christian Scientist" insisted that the patient did not have measles and that she should go about among the people at the house and among her pupils as she pleased.

This instance brings up a point that I wish to make. The attorney of the "Christian Scientists," Judge Tolman, has told us that this bill is an encroachment upon religious liberty, and he asks if the legislators of this state are willing to assume the responsibility of passing upon the religious belief of a large number of the citizens. Now, it is a matter well established in law that when the acts belonging to a religious belief are injurious to the community, they must be repressed. Last year the angel dancers of New Jersey claimed religious liberty, but their acts came under the practical consideration of New Jersey justices and a part of their religious liberty ceased. Judge Tolman brings up the matter of personal rights. In this case of measles in a house with twenty other people, the patient claimed the personal right to employ whom she pleased for a physician. What, I ask, were the personal rights of the other nineteen people in the house? They had the right of protection from a state which licenses its practitioners.

A "Christian Scientist" afflicted with a dangerous but curable disease has not even the right to treat himself, because attempted suicide under our New York statutes is a crime. Either Judge Tolman does not know the law relating to religious liberty, which is improbable, or else he has tried to mislead your honorable committee by the adroit use of words.

Mr. Norton has told us that this legislation against "Christian Science" would be legislation against Almighty God. Wait a moment. Infectious diseases are caused by bacteria. Bacteria are God's creatures—He wishes them to grow. If "Christian Science" treatment kills these creatures of God, the treatment which Mr. Norton would apply is apparently directly opposed to the will of God, although for my own part I am too humble to assume that I know His wishes.

Let me quote a specific instance showing the type of mind that is commonly found among the "Christian Scientists." Curiously enough I see the patient before me in the audience. Last year he came to my office with a tumor of the scalp, saying that he did not wish to have me treat it, but merely wished to show it to me, as it was growing smaller under his treatment by faith. I made a diagnosis of a sebaceous cyst and he paid my office fee for an opinion without a murmur. He returned again some months later to say that it was growing still smaller. It finally became so *"small"* that he had to have it removed! By the irony of fate it was in a position to be in plain view of all his brethren. This is simply an instance of self-delusion which is common among "Christian Scientists."

When the members of this audience who have been "cured of defective vision" by "Christian Science," and who have thrown away their glasses were asked to rise, about seventy-five arose. Now, all of these people still have the same errors of refraction that they had at the time when the glasses were thrown away, and I will ask you to remember this as a basis upon which to place an estimate of the character of many of the other cures. It is simply a matter of self-deception. These people will not admit that they still need their glasses, but members of their families or friends will tell us the truth about it, although some people with glasses improperly fitted are of course benefited by throwing them away.

I found a pathetic instance yesterday. One of the loveliest women whom I know had persuaded a poor woman who was short-sighted that she did not need her glasses any more. Her daughter tells me that she stumbles over chairs, falls in going up-stairs, can not thread her needle, and yesterday she stepped on the cat!

One of my old college friends who is now engaged in manufacturing proprietary medicines—and good ones—tells me that the testimonials of wonderful cures from the use of proprietary medicines that are published in the newspaper advertisements are not written in the office, as most of us suppose. He says he can put up brick dust if he wishes, advertise it sufficiently and receive by every morning's mail a pile of letters a foot high testifying to the wonderful cures that it has produced. This credulity is one of the traits of the human mind and is marked in an abnormal degree, to the extent of proselyting credulity, among the "Christian Scientists." It is simply a psychologic phenomenon. Psychology is physiology and abnormal psychologic manifestations simply represent a physiologic defect. It is like the matter of free will, which is no more free in man that it is in other animals, and which is determined by the organization of the individual and by the environment of the moment. . . .

I have not one thought of enmity toward the "Christian Scientists," not one unkind feeling. They simply need our care and the public needs to be protected against them when their acts become more harmful than beneficial.

We all know the powerful effect of the mind over symptoms of disease and even over disease. The successful physician makes use of it in his every-day round. I would frequently refer patients to "Christian Scientists" for the relief of sympf I knew any among these people who were responsible, e proportion of good which they do as compared to the resulting from neglect of cases for which they assume ibility would not appeal to your honorable legislators ifying their protection under our medical practice laws. nally, by religion I am a materialist, a monist, yet I he Christ of Ernest Renan and of Robert Speer that , my very flesh creep to use His name in the presence dience of blasphemous followers who charge money for etent services. Let me quote from the tenth chapter Luke, where Christ says to His followers: "And into oever city ye enter and they receive you, eat such things re set before you and heal the sick that are therein. . Carry neither purse nor scrip nor shoes." Most of the istian Scientists" whom I know at least carry their shoes! vill not charge "Christian Scientists" with being inten- ly blasphemous. There are few more attractive charac- nd no lovlier dispositions than those of some of the "Christian Scientists" whose minds are disabled by physiologic defect secondary to a certain physical degeneration or injury.

The high character of "Christian Scientists" is often quoted in justification of their acts, but it is no higher than the character of the judges who sentenced witches to be hanged and who represented the best classes in society. We do not justify the acts of these judges.

. . . Almost every year the newspapers contain accounts of some new healer who believes in himself and who is believed in by multitudes. The accounts of his miracles do not gain much momentum to-day, however, because they are readily explained by physicians who understand hysteria and trance death. There are text-books on the subject easily accessible for all of you. There are protean nervous derangements belonging to hysteria which are very amenable to the influence of the mind. There are many symptoms and some functional diseases not belonging to hysteria which are also under the control of the mind. Even such a disease as rheumatism, due to functional disturbance of the liver, might in some cases be controlled by mental stimulus sufficient to stimulate certain sympathetic nerves. No one denies the fact of many cures under mind treatment. We simply deny their supernatural nature and state that they are subject to *rational explanation*. We further must insist upon proper estimation of their proportionate value in the whole field of disease. It is this loss of the idea of proportion that sometimes leads very intelligent people astray when taking testimony. . . .

In view of the specific instances I have given of public danger and of personal injury resulting from the acts of these good "Christian Scientists," who for the most part are perfectly honest in their beliefs, I would ask your honorable committee to consider with great deliberation the advisability of allowing them the right to assume such responsibility as is required of physicians.

58 W. 56th St.

ANASTOMOSIS OF THE URETERS WITH THE INTESTINE.

A HISTORICAL AND EXPERIMENTAL RESEARCH.*

REUBEN PETERSON, M.D.
Professor of Gynecology Post-Graduate Medical School; Assistant *Clinical* Professor of Gynecology, Rush Medical College;
President of the Chicago Gynecological Society.
CHICAGO.

(Continued from page 507.)

Duval and Tesson,[4] 1900: *Three dogs; bilateral uretero-intestinal anastomosis; two dogs died of pyelonephritis.* These experimenters operated on three dogs, in each case implanting both ureters *in the* rectum. They combined the operative technique of Kryński and Fowler. The ureters were secured obliquely on a mucosal flap; over this flap were sutured the serosal and muscular layers.

One dog died twenty hours after the operation, from defective technique. Both ureters were found obliterated. One dog lived two and one-half months. Post-mortem showed the uretero-rectal *anastomosis* good; ureters patent. Bilateral pyelonephritis existed without distention. The third dog lived seven months. An autopsy showed the uretero-rectal orifices patent with slightly dilated ureters. Both kidneys were markedly distended and were the seat of grave pyelonephritic lesions. The mucous valves were atrophied so as to be unserviceable. The conclusions were that uretero-intestinal anastomosis could only be successful when the trigonum, together with the ureteral orifices, was transplanted.

Perhaps the most striking fact revealed by a study of these experiments is the exceptionally high mortality accompanying the operations, whether one or both ureters were implanted in the bowel. While it is impossible to accurately state the exact number of dogs operated on, because of the indefiniteness of the reporters in recording their work, I have endeavored, for the sake of comparison, to collect such data as are unequivocal.

Out of sixty dogs in which one ureter was implanted into the intestine there were twenty-three recoveries, or 61 per cent. mortality, while out of sixty-eight dogs undergoing bilteral ureteral anastomosis only ten survived, or a mortality of 85 per cent.

The mortality of the bilateral implantations is actually more than 85 per cent., since Martin does not state in what proportion of his thirty-four experiments were both ureters implanted, hence the entire number must be excluded, although his recoveries, numbering three, are included.

Again, among the ten dogs recovering from a bilateral uretero-intestinal anastomosis are three in which the ureters were implanted, not simultaneously, but at different stages. Since the danger attending implantation in two stages is obviously less than where both ureters are implanted, these three cases (Boari, one; Giordano, two) should, strictly speaking, be excluded.

The causes of death are various, but most prominent is peritonitis through a giving way of the uretero-rectal stitches and the subsequent escape of urine into the peritoneal cavity, or an overwhelming infection of the kidney ascribed to nephritis or uremia.

The different operative procedures employed may be conveniently divided into eight groups:

1. The severed ureter is inserted into the intestine through a small incision in the bowel wall and secured to the latter by sutures, which are passed through the intestinal serosa, and then either through the peritoneum removed with the ureter or its fibrous coats. (Glück and Zeller, Tuffier, Reed and Martin.)
2. A small incision is made through all the coats of the bowel and the ureteral and rectal mucosa sutured. The incision is then carefully closed about the ureter by Lembert's sutures. (Morestin.)
3. A V-shaped flap is formed in the anterior intestinal wall, to which the ureters are sutured. This flap is buried by suturing over it the lateral folds of the bowel wall. (Vignoni.)
4. A rectangular flap containing the ureteral orifices is inserted into the bowel through an incision in its anterior wall. This flap is sutured to the freshened mucosa on the posterior wall of the bowel. (Pisani.)
5. A ligature with a needle at each end is passed through the end of the severed ureter. The nedles are passed through a small slit made in the bowel wall and brought outside the intestine from one-half to one inch below. The two ends are made taut and the ureter is drawn into the bowel. The ureter is then secured in position by sutures. (Bardenhauer, Reed and Van Hook.)
6. The ureters are buried under the serosa and muscles of the intestinal wall and secured in place by sutures uniting the ureteral and intestinal mucosa, or drawn into the bowel as described under method 5. The muscular and serosal flap is then sutured over the ureters. (Kryński and Martin.)

---

* Read before the American Gynecological Society, Washington, D. C., May 1, 1900.

7. The ureters are secured to a mucosal flap valve and buried obliquely under the serosa and muscularis. (Duval and Tesson.)

8. The anastomosis of the ureter and intestine is made with a mechanical device, which, after union is secured, passes into the intestine. (Boari.)

As has been shown, the primary mortality was exceedingly high with all these methods. The method which calls for the least amount of suturing of the ureter itself will be found to give the best results. (Reed and Van Hook.)

A number of methods were devised with a view of preventing an ascending infection, but these efforts did not meet with success. I have been unable to find a single case in which the kidneys were shown to be normal beyond dispute. One can hardly accept such loose statements as those made by Kryński, who, in speaking of the results of his new operation, says he has never seen disease of the kidneys or ureters follow its use, yet fails to give his experiments in detail. Again, Boari, in describing the specimens removed from an uretero-rectal anastomosis, states that macroscopically the kidneys presented no grave lesions.

The post-mortems on the animals surviving the operation for any length of time in nearly all instances showed unmistakable evidences of stenosis of the ureteral orifice, hydroureter, hydronephrosis, and pyelonephritis. In only a few instances were bacteriologic or miscroscopic examinations made, and without such examinations proof of the integrity of the organs can hardly be conclusive.

The most carefully conducted examinations were made in Martin's cases, and they showed in every instance inflammatory changes. As already pointed out, Novaro's case failed to demonstrate that the kidneys and ureters of the animal living four months were normal. In Reed's and Boari's cases the specimens were not examined microscopically, and the same may be said of Kalabin's cases. Briefly stated, the collective experimental results of uretero-intestinal anastomosis without the preservation of the vesico-ureteral orifices have shown that the operation is a failure, either primarily from defective technique, or from overwhelming renal infection. The surviving animals showed grave kidney lesions, the result of preceding pyelonephritis. Frank's experimental work with the vesico-rectal anastomosis will be discussed in connection with the report of a case operated upon by his method.

In order that the value of the conclusions to be drawn from recorded cases of uretero-intestinal anastomosis in man may be correctly estimated, short abstracts of the cases will be given as nearly as possible in chronologic order.

It is obviously impossible to be exact chronologically, since in quite a few instances the date of the operation has not been included in the report. Under the circumstances I have arranged the cases according to the date of publication of the article containing the report.

SIMON,[42] 1851. *Bilateral uretero-rectal anastomosis; death one year after operation; inflammatory changes in ureters and kidneys.* The first attempt to deviate the course of the urinary flow into the rectum was made by John Simon in 1851. He reasoned that in reptiles and birds the genito-urinary and digestive tracts ended in a common cloaca, and that there was no good reason why this anatomical arrangement should not be artificially produced in man. He also called attention to the sphincteric control over the urine possessed by those individuals who, after being operated on for vesical stone by way of the rectum, were left with vesico-rectal fistulæ. These views he proceeded to put to a practical test in the case of a 13-year-old boy who came under his care suffering from exstrophy of the bladder. The operation was performed July 5, 1851. By a specially devised instrument Simon succeeded in passing threads from the ureters into the rectum, so that, when tightened, pressure necrosis took place and uretero-rectal fistulæ were formed. By the tenth day some urine passed per anum. Three weeks after the operation most of the urine flowed directly into the rectum. At the end of three months an unsuccessful attempt was made to close the natural ureteral orifices. Seven months after the operation the openings into the rectum were still patent, although considerable contracted. The patient died of exhaustion twelve months subsequent to the operation. At the autopsy the ureters were found blocked with calculi the size of peas or beans. The ureters and kidneys were seriously diseased, the pathologic changes being due to the surgical method employed which had "excited suppurative inflammation along the mucous surface of the ureters."

ROUX,[40] 1853. This experimenter, evidently without any knowledge of Simon's case, proposed that the ureters be sunk in the rectum and that the exstrophied bladder be covered in by skin through plastic operations. His plan was either to separate the ureters from the vesical tumor and suspend them in the rectum through an opening made in that organ, or to form uretero-rectal fistulæ by dividing the tissues separating the ureter and rectum. Roux was led to believe that these operations were anatomical possibilities from a study of cases where the ureters congenitally opened into the rectum and from the numerous instances on record where, after the removal of a vesical stone and the establishment of vesico-rectal fistulæ, the patients were still able to control their liquid evacuations. He refrained from putting these ideas into practice because of his uncertainty as to the relations of the peritoneum and rectum in exstrophy of the bladder.

SMITH,[43] 1878. *Bilateral uretero-colonic anastomosis, extraperitoneal method in two stages; death from uremia immediately after last operation; atrophy of one kidney; inflammatory changes in the other.* Over a quarter of a century elapsed before another attempt was made to unite the ureters and intestinal tract directly. Then Thomas Smith, in 1878, operated on a boy, aged 7, afflicted with exstrophy of the bladder, by a new technique. A bougie was passed up the left ureter and an opening made in left loin; the ureter was then located and inserted into the descending colon. It was held in position by fine carbolized catgut passed through the bowel and through cellular tissue about the ureter. For six days the urine passed with the feces with no unusual irritation of the bowel except that the movements were more watery and frequent than natural. On the ninth day feces and urine passed through the incision in loin. There was later free suppuration in or around the kidney, the abscess opening in the loin at site of wound. Fistulous opening gradually closed. One year after the operation the boy was in good health, no urine escaping from left ureteral orifice.

Second operation fourteen months after first. The right ureter was inserted by the same method into the ascending colon, fine wire sutures being used instead of catgut. The patient became drowsy, and died fifty hours after the operation

Autopsy.—Pelvis of left kidney distended with clear fluid and the organ reduced to a fibrous condition. The ureter was one and a half inches in length and the uretero-rectal opening was not patent. The right kidney was much enlarged and the capsule was adherent to the cortical substance, which was soft and pliable. The pelvis of this kidney and corresponding ureters were dilated. A small probe could be made to pass through the ureterorectal opening only with great difficulty.

KÜSTER,[36] 1891. *Both ureters in rectum, following removal of bladder; death in five days from peritonitis and renal infection.* In 1891 Küster removed the bladder and prostate from a patient aged 53, for malignant disease. The operation was performed by the perineal and abdominal route. The ureters were cut off from the bladder obliquely, the rectal and ureteral mucosa being united by one series of sutures, and then reinforced by a row of sutures externally. The patient lived five days. The autopsy showed purulent peritonitis and undoubted renal infection. The ureters were not dilated, but the sutures uniting them to the rectum had not held.

CHAPUT,[30] 1892. *Case 1. Uretero-vaginal fistula; right ureter united to rectum; recovery; well after eight years.* September 13, 1892, Chaput operated upon a woman, aged twenty-nine for a uretero-vaginal fistula, resulting from a vaginal hysterectomy. The abdomen was opened and the enlarged right ureter was united to the rectum by a series of sutures, one set uniting the mucous, the other the serous surfaces. Convalescence was uneventful.

In a personal communication to the author, dated April 3, 1900, Dr. Chaput states that the patient is still alive, although the operation was performed eight years ago. Her health is very satisfactory and there are no signs of renal infection. She has about three liquid evacuations in twenty-four hours.

Case II. Tubercular cystitis: double uretero-colonic anastomosis in two stages; death from uremia after last operation. A woman, aged forty-five years was operated upon November 25, 1892, for a chronic tubercular cystitis which had not yielded to a suprapubic cystotomy. Through an abdominal incision the left ureter, as large as the little finger, was located and sutured into the descending colon by the same method described in Case I. Cure was rapid and complete. Eight watery stools per day. Three months later, March 1, 1893, the right ureter, as large as the thumb, was united to the cecum by the same method. No fever resulted, but the patient became comatose and died the same day. The existing diarrhea was checked. Suppression of urine was the undoubted cause of death. No autopsy was performed.

Rein,[30] 1894. *Exstrophy of the bladder; bilateral uretero-rectal anastomosis; death.* Rein, at the International Congress at Rome, 1894, reported the case of a woman, aged twenty, upon whom he had operated for exstrophy of the bladder.

An incision 16 cm. in length was made across the ectopic bladder. The uterus and left adnexa were removed and a bougie introduced into the left ureter. A good-sized drainage-tube was introduced into the rectum and both tubes approximated. An incision a few millimeters in length was made at this point in the rectal wall and a glass drainage-tube, previously passed into the ureter, was carried through this incision into the rectum. An elastic drainage-tube was attached to the tube already in the ureter and carried out through the anus. The artificial uretero-rectal fistula was closed by sutures in two layers. The same operation was performed on the other side. The ectopic bladder was now extirpated and all hemorrhage controlled. A perfect union of the abdominal wall was impossible because of the considerable separation of the ossa pubis and the recti-muscles. The operation consumed two hours and fifty-two minutes. The patient died in a short time.

Duplay,[31] 1894. *Case I. Exstrophy of the bladder; both ureters in sigmoid; death from pyelonephritis.* Duplay, in an article on exstrophy of the bladder, speaks of having operated upon a girl aged eight, by implanting the ureters into the sigmoid flexure. The patient died in a few months of pyelonephritis.

Case II. Same as above; death. Mazel (page 483) refers to Duplay's article, and a written communication from Duplay, in which the latter mentions a second girl, aged ten years, operated on by him for exstrophy of the bladder. Both ureters were implanted in the sigmoid flexure with fatal results.

Trendelenburg,[44] 1895. *Extirpation of one kidney and bladder; uretero-sigmoidal anastomosis; death from extension of tuberculosis.* Trendelenburg reported a case where the right kidney was extirpated for tuberculosis. The entire bladder, except a small piece in which ended the left ureteral orifice, was also extirpated for extensive tubercular disease. This ureter was implanted in the sigmoid flexure and prevented from slipping out by the attached portion of the bladder. Functionally the operation was a success, but the patient subsequently succumbed to tuberculosis of other organs. (While the ureteral orifice and its mucosa was retained in this case from the method employed in its implantation, the probability is that the end of the ureter sloughed, and the insertion into the bowel in no way differed from those cases of implantation where the ureter was cut off external to the bladder.)

Boari,[27] 1895. *Vesico-vaginal fistula; left ureter in descending colon; well six months later.* Boari, by means of his anastomotic button, grafted the left ureter into the descending colon in a case of vesico-vaginal fistula, with complete destruction of the urethra. The patient lived, and six months later was in perfect health, passing the urine, partly by the anus and partly by the vagina, every three or four hours, without inconvenience. The operation was made extraperitoneally through a curved incision, reaching from the middle of Poupart's ligament to the anterior superior spine of the ilium. The posterior parietal peritoneum was opened and the colon secured, and after the graft was made was fastened extraperitoneally.

The Boari button is to be used preferably by the extraperitoneal route. It is best described by drawings which are given below. (Figs. 4-9.) A button suitable to the caliber of the ureter should be chosen. The ureter is invaginated upon the tube and tied with silk. Then the movable plate is lowered until it meets the under plate and is held in place by a stylet which passes through the bottom tube. A purse-string suture is passed in the bowel and an opening made just large enough to allow the rectal plates to slip in. The suture is now drawn taut and the stylet removed, and the spring carries the rectum against the ureter.

Casati,[28] 1895. *Vesical tuberculosis; left uretero-colonic anastomosis; death in thirty-five days of tuberculosis.* Boari reports a case operated upon by E. Casati where the former's anastomotic button was employed for very advanced vesical tuberculosis. The left ureter was grafted into the descending colon with the intention of later making a graft of the right ureter and removing the bladder; but the patient lived but thirty-five days after the operation.

No report is made of the passing of the button or the nature of the rectal discharges. Neither are the post-mortem findings recorded.

Chalot,[29] 1896. *Cancer of uterus; bilateral uretero-rectal-anastomosis; recovery; living one year after operation.* July 22, 1896, Chalot operated upon a woman, aged 45, for uterine carcinoma with involvement of the broad ligaments. The abdomen was opened in the median line, and the left ureter isolated and ligated. The central end was dilated and implanted into the rectum by means of the Chalot anastomotic button. The ureteral end of the button was retained in place by a circular ligature. The internal iliac artery was then ligated. In the same way the right ureter was anastomosed with the rectum and the right internal iliac artery ligated. The uterus, appendages, and broad ligaments were then removed with but little hemorrhage. Gauze drains were inserted through the vagina and at the lower angle of the abdominal incision. A large tube was left in the rectum. Convalescence was uninterrupted. The gauze was removed gradually, with no leakage of urine. All the urine passed by the anus. For the first month the patient suffered from diarrhea, having three to four stools an hour, but this condition gradually improved.

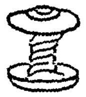

Fig. 4.

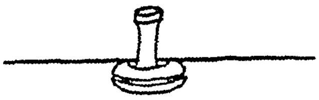

Fig. 5.

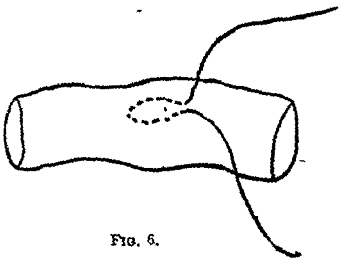

Fig. 6.

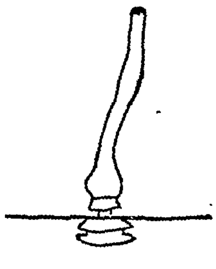

Fig. 7.

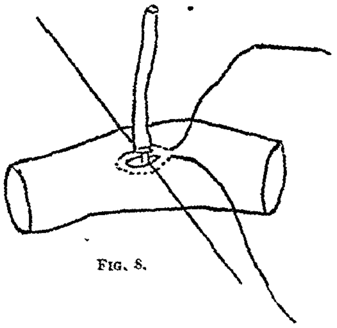

Fig. 8.

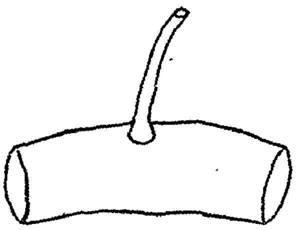

Fig. 9.

Chalot's tube for anastomosing the ureters with the intestine is made of nickel and is cone-shaped at each end. It is 3.5 cm. in length and is hollow, its inside diameter measuring from 1/3 to 3 mm., 1½ cm. from one end and 2 cm. from the other is a groove which is large enough to receive a loop of thread, which is tied around the end of the tube. The rectal end of the tube is perforated so as to permit the introduction of a thread by means of which the tube may be withdrawn, later, if desired.

Figs. 10 and 11 show the method of securing the tube to the bowel-wall.

Fowler,[33] 1896. *Exstrophy of bladder; bilateral uretero-rectal anastomosis; recovery; well three and a half years after operation.* Fowler operated upon a boy aged six September 20, 1896, for exstrophy of the bladder. The abdomen was opened in the median line. The posterior layer of the peritoneum was incised, the ureters exposed and cut away at their attachments to the bladder-wall. An incision 7 cm. long was then made in the anterior wall of the rectum through the serous and muscular coats of the bowel. The edges of the incision were retracted and a tongue-shaped flap of mucous membrane with its base directed upward was cut from the mucous membrane in the lower half of the diamond. This tongue-shaped flap was doubled upon itself in an upward direction in such a manner that one-half of its mucous surface presented anteriorly, where it was secured by two catgut sutures. A flap-valve was thus formed, both sides of which were covered with mucous membrane. The ureters were then placed in the incision so that their obliquely-cut ends lay upon the presenting mucous membrane of the flap. The ureters were secured in position by catgut and the flap-valve pushed into the cavity of the rectum, and the wall of the latter closed by catgut sutures. The original wound in the rectal wall was closed with fine silk sutures. The patient promptly recovered. The rectum was tolerant of the urine, which was passed per anum on an average every three hours. Defecation occurred about once daily, and the movement was generally formed.

In a personal communication dated March 14, 1900, three and a half years after the operation, Fowler writes: "In reply to your inquiry concerning the condition of the boy upon whom I performed the operation of implantation of the ureters, I am glad to inform you that he is and has been since the operation in good health. There are no indications of renal infection."

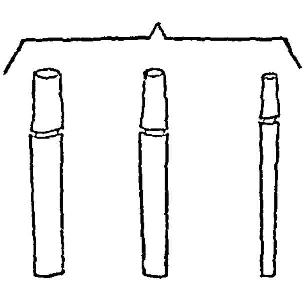

Fig. 10.

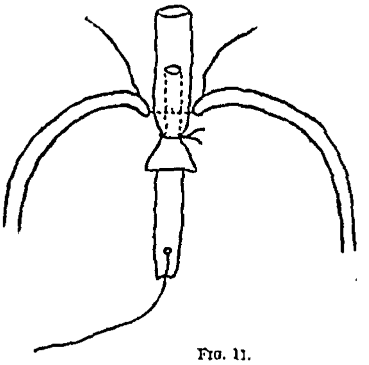

Fig. 11.

Tuffier et Dujarnier,[46] 1896. *Removal of bladder for malignant disease; bilateral uretero-rectal anastomosis; death seven months later; causes unknown.* The operation was performed upon a man, aged forty, who had suffered from frequent micturition and vesical hemorrhages from a malignant growth confined to the bladder-wall. October 20, 1896, the bladder was removed and catheters fastened in the severed ureters. Each ureter was then passed through an incision made on either side of the rectum and fastened outside the anus to forceps to prevent backward displacement. The operation was followed by symptoms of sepsis. Six days after the operation urine passed by way of the hypogastric opening. Two months after the operation the patient was able, by wearing a receptacle for his urine, to attend to his business. The patient died seven months after operation, of unknown causes.

Fritsch,[31] 1897. *Bilateral uretero-rectal anastomosis; death from pyelonephritis.* Fritsch, in the *Handbuch der Gynäkologie*, mentions, in discussing the question of uretero-rectal implantation, that he has performed the operation on one patient and that death resulted from pyelonephritis. Therefore he condemns the operation.

Tuffier,[45] 1897. *Uretero-vaginal fistula; left uretero-colonic anastomosis; recovery.* Tuffier implanted the left ureter in the descending colon, the lumbar route being employed. The woman was suffering from a uretero-vaginal fistula, the upper end of the ureter being in such a position as to make a uretero-cystotomy impossible. The woman recovered from the operation, and showed no signs of renal infection.

Von Winiwarter, 1898. *Removal of bladder; uretero-rectal anastomosis; recovery with fistula.* The operation was performed January 3, 1898. The urethra and prostate were first exposed and separated from the rectum. The pubic bones were separated and the bladder severed from its attachments and removed. The ureters were catheterized and sutured into the antero-lateral walls of the rectum. The catheters were removed in forty-eight hours and urine flowed through the anus. Five weeks after the operation the pains had disappeared and the patient had gained in flesh. Most of the urine escaped from a fistula in the anterior wall of the rectum, causing itching in anal region.

Schnitzler,[41] 1898. *Case I. Uretero-vaginal fistula; right uretero-colonic anastomosis; recovery.* The operation was performed for the relief of an uretero-vaginal fistula following a vaginal operation. The right ureter was implanted in the ascending colon. Immediate result satisfactory. Ultimate result not mentioned.

Case II. Vesico-vaginal fistula; bilateral uretero-colonic anastomosis; death in a few days; pyelitis. Operation was performed for the relief of a vesico-vaginal fistula arising from carcinomatous ulceration, the radical removal of the malignant growth being impossible. The right ureter was implanted in the ascending, the left in the descending colon. The patient died in a few days, and on the left side was found a severe pyelitis, which probably existed in some degree before the operation. There was also necrosis of some portions of the mucous membrane of the ascending colon, which came in contact with the urine.

Evans,[32] 1899. *Absence of right kidney; abscess of left kidney, which was opened in loin; left uretero-rectal anastomosis; recovery; thirteen months after operation living and well.* Through the kindness of Dr. Evans I am allowed to give an abstract of this interesting, unpublished case. The patient was a man, aged twenty-three, who had had a suprapubic cystotomy July 16, 1898, for chronic purulent cystitis of long standing. Left ureter catheterized; right could not be found. November 28, left kidney opened and large amount of pus evacuated; ureter greatly thickened. February 18, 1899, left ureter was implanted into rectum just below the brim of the pelvis by an extraperitoneal incision. Ureter allowed to project one-half inch into the rectum and united to the bowel by silk and catgut sutures. Gauze drain in each angle of wound. For four days urine did not pass freely through rectum, although water could be made to pass into the rectum by way of the loin. Nine days after operation a small amount of feces escaped through lower angle of incision. Two days later both loin and bladder fistulæ were closed and bowels moved often with watery stools after implantation of ureter. No urine passed by bladder fistula or by penis, showing absence of right kidney. Four months after operation the fistula in the loin reopened and discharged for a number of weeks. Thirteen months after the operation patient is in good health and is working every day. The fistula in the loin has discharged for past five months, and at present leaks only at night and not at all during the day, when bowels move three or four times. There never has been any rectal irritation; suprapubic wound is firmly closed.*

Turetta, 1899. *Removal of bladder; bilateral uretero-rectal anastomosis with Boari's button; death; autopsy showed suppurative nephritis.* Turetta reported before the Congress of Italian Surgeons the case of a man, aged 23, upon whom he had performed total extirpation of the bladder, with implantation of the ureters into the rectum. For several months the patient had suffered from severe hematuria. Examination revealed a hard growth confined to the bladder wall. March 1, 1899, the bladder was resected through a temporary separation of the os pubis and the ureters anastomosed with the rectum by means of Boari's buttons. The urine passed *per anum* until the third day, when the flow ceased and the urine escaped by the incision. Attempts to seize the ends of the ureters failed. Symptoms of nephritis now supervened and became more and more marked until the death of the patient on the sixteenth day after the operation. The autopsy showed suppurative nephritis; the pyramids contained small abscesses.

Peters, 1899. *Exstrophy of the bladder; bilateral extraperitoneal uretero-rectal anastomosis; recovery; good health ten months after operation.* Peters exhibited a boy, aged 4½, before the Canadian Medical Association, upon whom he had operated five weeks previously for the cure of exstrophy of the bladder. Two years before he had operated successfully for procidentia recti. In July, 1899, the ureters were implanted into the rectum extraperitoneally, one on either side of the bowel. Good control over the sphincter ani resulted, the patient having evacuations every three hours during the day and every four or five hours during the night.

In a personal communication dated March 30, 1900, Dr. Peters states that the patient is in perfect health ten months after the operation. Able to retain urine three, four, and five hours during the day and eight hours at night. No eczema about the anus. The ureteral openings appear as two prominent papillæ in the antero-lateral aspect of the rectum, about one-half inch above the internal sphincters. Urine quite normal in quantity and percentage of urea.

---

* Feb. 1, 1901. Patient died about two months ago. Autopsy showed atrophy of right kidney, pyelonephritis of left.

WALSHAM, 1899. *Left uretero-colonic anastomosis; ureteral orifice became stenosed, with subsequent destruction of kidney.* Walsham mentions a case seen by him where the end of the left ureter was implanted in the descending colon. The artificial opening became obliterated by cicatricial contraction, with subsequent destruction of the corresponding kidney.

KRAUSE, 1899. *Removal of the bladder for malignant disease; implantation of both ureters into the sigmoid; recovery; well three and one-half months after operation.* The operation was performed upon a patient, aged 17, three and one-half months before the report. For a year he had suffered from a tumor involving the base of the bladder and completely obstructing the left ureter. The bladder was removed by the extraperitoneal route. The peritoneum was opened four times, but immediately closed with catgut sutures. The vesicules seminales were left in place. The ureters were not sutured into the rectum because of the extremely low position of the peritoneal cul-de-sac and the correspondingly extreme traction which would have resulted. They were sutured into a coil of the sigmoid flexure, which was drawn down through an incision in the posterior cul-de-sac. Two tiers of sutures were employed; the result was excellent, the convalescence being afebrile and a gain of ten pounds in weight resulting. He can control his urine for two hours and can rest from five to six hours at night.

In 1897 Krause performed a similar operation on a man with carcinoma and existing pyelitis. Patient lived but a short time and died of pyelonephritis.

BECK, 1899. *Tuberculosis of bladder; bilateral implantation of ureters into sigmoid; recovery; well seven months after the operation.* Beck showed a man before the Chicago Medical Society whose ureters he had implanted in the sigmoid flexure for tubercular disease of the bladder. After the formation of a peritoneal and muscular flap in the gut wall a small opening was made in the mucosa, through which the ureters were drawn one and one-half inches into the bowel; the ureters were then sutured in a groove of the bowel wall. The patient made a good recovery, and presents no evidence of pyelonephritis eight months after the operation. Beck believes that this freedom (?) from infection is due to the fact that the ureter, being left free in the bowel, offers a barrier to ascending infection of the ureter and kidney by doing away with necrosis and the formation of granulation about the mouth of the ureter.*

W. C. WOOD, 1899. *Exstrophy of the bladder; bilateral uretero-rectal implantation; death in two months from pyelonephritis.* Wood showed before the Brooklyn Pathological Society the kidneys of a patient, aged five, upon whom two months previously he had operated for exstrophy of the bladder. The ureters were implanted into the rectum according to the technique advocated by Fowler, with the exception that the implantation was performed higher up in the bowel. The patient died in two months of pyelonephritis.

MARTIN, 1900. *Four cases of uretero-rectal anastomosis with three deaths; operations performed for exstrophy of bladder, tuberculosis of bladder and carcinoma of bladder. Case I.* Exstrophy of the bladder in a boy, aged 14. The right ureter was implanted into the rectum extraperitoneally. A second operation upon the left ureter was a failure. The urine was passed *per rectum* every six hours, independent of fecal matter. At first there were casts in the urine passed *per rectum.* Eighteen months later the boy was perfectly well.

Case II. Tuberculosis of the bladder in a man, aged 30. The bladder was removed and the right ureter implanted in the rectum; the left ureter in the skin. A ureteral catheter was employed. The patient died of shock and suppression of urine twenty-six hours after operation.

Case III. A woman, aged 37, was operated on for carcinoma of the uterus and bladder. The ureters were implanted in the rectum by the Martin method. Urine flowed through the ureteral catheters and the anastomosis was found perfect. Died in four days of peritonitis.

Case IV. The carcinomatous bladder and uterus were removed from a woman, aged fifty-four years, and the ureters implanted in the rectum. The patient died four hours later of shock.

RESUME OF 33 URETERO-INTESTINAL IMPLANTATIONS.

Number of patients operated upon			29
Number of operations			33
Number of operators			22
Conditions for which operations were performed stated in			31
Chronic cystitis			3

Poor functional result			5
Of the 22 recoveries primarily from the operation, ultimate results not mentioned in			1
Failure			1
Died later of tuberculosis of other organs			2
Died seven months later, cause unknown			1
Died later, pyelonephritis			3
Died of uremia subsequent to implantation of other ureter			2
Kidney destroyed by stenosis of uretero-rectal orifice			1

OF THE REMAINING 11 CASES.

1 ureter implanted, well after	6 months.
1 ureter implanted, well after	13 months.
1 ureter implanted, well after	18 months.
1 ureter implanted, well after	2 years.
1 ureter implanted, well after	8 years.
2 ureters implanted, well after	5 weeks.
2 ureters implanted, well after	3½ months.
2 ureters implanted, well after	7 months.
2 ureters implanted, well after	10 months.
2 ureters implanted, well after	1 year.
2 ureters implanted, well after	3½ years.

A critical survey of these thirty-three operations shows the primary mortality, 33 per cent., to be exceedingly high. If to this be added the uncertainty as regards subsequent renal infection in the cases surviving the operation, it must be admitted that uretero-intestinal anastomosis is not an operation of choice.

(To be continued.)

---

* Feb. 23, 1901. Patient died some weeks ago. Autopsy showed marked bilateral pyelonephritis.

SATURDAY, MARCH 2, 1901.

DIABETES MELLITUS.

It seems probable that diabetes has long been recognized, although the presence of sugar in the urine, from its sweetish taste, was first detected in the seventeenth century, and it was not until the eighteenth that glucose was isolated. Then followed a careful description of the disease, with the recommendation of an animal diet and exclusion of vegetable food in treatment. Scientific study of the etiology, nature and treatment of diabetes, was, however, not begun before the middle of the nineteenth century, but since then few diseases have had more attention devoted to them, both clinically and experimentally. In an interesting communication, von Noorden[1] discusses some as yet unsettled questions in this connection, and points out the lines along which scientific investigation may profitably be directed. Quite apart from increased thoroughness of clinical study, there is scarcely room for doubt of the increased morbidity and mortality of diabetes.

With regard to the question of etiology, emphasis has been placed upon the influence of alcoholic excess, heredity and race. The especial predisposition of the Jews to diabetes has attracted attention, and it is suggested that their dissemination and admixture with Indo-Germanic blood may have something to do with the more widespread prevalence of the disease.

A satisfactory explanation for the excretion of sugar by the diabetic patient is yet wanting. This has been thought to be due to the presence of an increased amount of sugar in the blood, but it has been shown experimentally that sugar may appear in the urine as the result of certain forms of intoxication, without an excess of sugar in the blood. The latter phenomenon has been attributed to special activity on the part of the kidneys, and the condition has been designated renal diabetes. In addition to glucose, combinations containing it may be present in the blood. In general it is agreed that the sugar of the blood and the urine is derived from carbohydrates, especially hexoses and pentoses, but it has been shown that it may be derived also from certain proteids and from fat.

Among the special metabolic processes peculiar to diabetes are the production and elimination of non-nitrogenous substances belonging to the fatty-acid series, namely, acetone, diacetic acid, and beta-oxybutyric acid. These three are closely related, not only clinically, but also pathologically. When the urine and the expired air contain little acetone, diacetic acid and beta-oxybutyric acid also are as a rule absent. When much acetone is present, diacetic acid likewise will be present; and when there is much of the latter, there will generally also be beta-oxybutyric acid. It seems probable that beta-oxybutyric acid is the parent substance, appearing in the urine only when produced in large amount, or when reduction in the alkalinity of the blood prevents its transformation into diacetic acid. The presence in the blood of the acids named is responsible for the large elimination of ammonia that is observed in cases of marked diabetes. It is not known why the diabetic produces so much beta-oxybutyric acid or diacetic acid, but this is favored by exclusion of the carbohydrates from the diet. The source of the beta-oxybutyric acid is believed to be the proteids and the higher fatty acids. The most important fact in this connection is that diabetic coma is almost always associated with the presence of large amounts of beta-oxybutyric acid or its derivatives in the blood; but whether the coma is dependent upon the acid or upon an intoxication peculiar and specific to diabetes, or to both of these influences is, as yet, a matter for discussion.

It is no longer believed that the general metabolism is increased in cases of diabetes, with resulting emaciation and increased demand for food. The oxidation processes are not greater than in a healthy individual under normal conditions, and the emaciation is due to loss through the urine, as sugar, of a part of the energy supplied by the food ingested. As a rule, further, the proteid metabolism of the diabetic is normal. Exceptionally, in the terminal stage, before the onset of diabetic coma, toxogenic proteid metabolism may occur in accordance with the character of the diet. The diabetic exhibits a tendency to suffer from loss of lime, and this is thought to be due to the presence of organic acids in the blood. Absorption of food from the stomach and the intestines, however, pursues a normal course. In some cases, on the other hand, absorption of fat and proteids is impaired. Under such circumstances it is probable that the secretion of pancreatic juice is interfered with, and, clinically, administration of pancreatic extract has proved serviceable.

There is yet much to learn in connection with the pathogenesis of diabetes. It is known that lesions of the floor of the fourth ventricle, intoxication with phlorídzin, and total destruction or extirpation of the pancreas, may, among other things, give rise to the manifestations of the disease. Clinically, diabetes may be considered a derangement of metabolism of varying degree, and with corresponding variations in the intensity of the symptoms to which this gives rise. In the line of treatment no great advance has been made beyond that of rigid dietetic individualization. There is no effective medicinal remedy, although opium and its alkaloids, as well as antipyrin, salicylic acid and jambul, are capable of diminishing the elimination of sugar, but their effect is uncertain and transitory, and the injury resulting from their long-continued use is greater than the temporary benefit.

---

[1] Berliner klin. Woch., 1900, Nos. 49 and 50.

RECENT VIEWS CONCERNING THE GENESIS OF CARCINOMA.

Ribbert's opinions as to the early participation of the underlying connective tissue in the development of carcinoma have been the subject of a severe arraignment by Lohmer.[1] For a considerable period, chiefly through the work of Thiersch and Waldeyer, the origin as well as the further growth of carcinoma was held to be directly due to the proliferation of the epithelium into the deeper tissues. Ribbert and his pupils diverged from this conception in that they traced the origin of the tumor to a disconnection of the epithelial cells from their associates by processes in the subepithelial connective tissue; following such dislocations, the loosened cells proliferated to form a tumor. Such severances are, according to Ribbert, produced by the growth of the connective tissue into the epithelium, by the lengthening of the papillæ of the corium so that the interpapillary epithelial pegs become correspondingly drawn out and ultimately separated, and by the pushing outward of the epithelium *en masse* by the increased amount of tissue in the corium. There is no doubt that Ribbert's theories have been of great service in stimulating study of the dynamics of the process; nor is there any question but that they minimize, to insignificance, the important change in the epithelium whereby the cells proliferate and undergo the marked morphologic alterations that Hauser and others believe to be the visible signs of altered biologic conditions. Lohmer, in a careful study of serial sections of eight carcinomas of the lip, of carcinomas that originated in sebaceous glands and hair follicles, in the mammary gland, penis, forehead, nose, tongue, pancreas, and different parts of the gastro-intestinal tract, has failed entirely to find adequate histologic evidence to support the views of Ribbert. He was able to prove that certain cases originated solely by the proliferation of the epithelium inward, that elongation of the interpapillary epithelium in many cases was absent, that on the border of glandular carcinomas, the new glands are produced by the proliferation of pre-existing glands, and, what is still more interesting, he was able to find in some carcinomas that two or more entirely independent foci of proliferation were present. He is forced to the conclusion that we must return to the former views of Thiersch and Waldeyer, that the multiplication of the epithelial cells is alone responsible for these growths.

The reasons for the increased proliferative energy of the cells whose end product is a tumor have been theoretically assumed, by Brosch,[2] to be due to a double stimulus. He believes that the initiatory changes are reparative in nature, and that when these are unable to restore the damaged parts the added energy causes them to multiply still further and to produce such an amount of new tissue that tumors are formed. He distinguishes two forms of proliferation, that called forth in the response of the tissues to injury—essentially teleologic—and such as occurs in tumors. The proliferation of cells in consequence of physiologic waste and wear, he would designate by the name regeneration. Upon this assumption he has made careful re-examination of Lowenthal's tables[3] and finds that in many cases injury to parts in which reparative processes were already commenced has caused tumors; the second injury has been sufficient to supply the stimulus necessary to cause proliferation that far oversteps the requirements. Many cases of carcinoma that develop in the cicatrices of burns belong to this category. In some cases in which a positive history of previous trauma was lacking, the defect was filled by careful inquiry into the occupation and habits of the individual. He quite correctly calls attention to the impossibility of obtaining positive information about the traumatic injuries to the surface of the gastro-intestinal canal—situations where trivial harm is fully as important as extensive injuries upon the outer surface.

There is much that is interesting and attractive about the theoretical axiom erected by Brosch of trauma-proliferation, trauma-tumor, and one of the most valuable supports to this view is afforded by the occurrence of malignant growths following trauma of benign tumors. He attributes the repeated failure of previous investigators to produce tumors by implantation experiments to the absence of certain factors in the causal chain, and to the necessity of experimentation upon a productive process that has already been established. Upon this basis he bruised the skin of the back of a guinea-pig and, after a granulating wound had formed, rubbed it at intervals with a solution of paraffin in xylol; after some weeks a very characteristic ulcer was produced, resembling the cerebral convolutions in miniature; the elevations in the floor of the ulcer were caused by an atypical epithelial growth that in all respects resembled an early carcinoma. The experiments have not as yet been conducted to the end that regional and general metastatic growths are reported. It will be noted that these two important contributions to the subject of tumor genesis do not necessarily conflict with the parasite theories of tumors.

THE BOSTON MEDICAL LIBRARY.

After twenty-five years of untiring effort the Boston Medical Library Association, originally composed of six physicians, on January 17 dedicated its new and complete building by interesting and appropriate exercises. A series of short addresses, admirably suited to the time and place, were given by men from Boston, New York, Philadelphia and Baltimore. Any one really interested in the question of medical libraries can derive much pleasure and profit from reading the various addresses.

---

[1] Ziegler's Beitraege, 1900, xxviii, 372.

[2] Virchow's Archiv, 1900, clxii, 32.

[3] Archiv f. klin. Chir., Bd. xlix.

The Boston Medical Library is the fourth in size in the country, being exceeded by that in the Surgeon-General's office in Washington, that of the College of Physicians of Philadelphia, and that of the Academy of Medicine in New York. It contains about 33,000 volumes and 30,000 pamphlets; it receives about 500 periodicals. To adequately house a growing collection of this kind and to furnish suitable and inviting facilities for its daily use require a commodious, specially constructed building; and the Boston Medical Library now has a fitting domicile in a chaste and appropriate building on one of the most attractive streets, "commanding a view of exceeding beauty." For erecting this building $73,000 were collected by subscription; the total cost is $140,000; the association has $25,000 in land, so that there is a balance of debt of $42,000. It seems that the money has been secured wholly through the medical profession of Boston. The new building is planned to be of use to the profession and the community in other ways than as a library. A directory for nurses is conducted within it; and by an admirable foresight, which it is hoped may come into play in connection with similar undertakings elsewhere, suitable halls for the meetings of various medical societies have been added. Portraits of past worthies ornament the walls, and the memory of Oliver Wendell Holmes is to be kept green by naming the principal reading room Holmes Hall; this room contains many Holmes mementoes. It is pleasant to note that the amenities of the social side of professional life have been so well cared for as to provide smoking room and supper room. Indeed, it is proposed and was urged by some of the speakers to enlarge the scope of the functions of the library so as to include those of a society or academy, making the institution similar to the Academy of Medicine in New York and the College of Physicians in Philadelphia. This subject is certainly an important one; its treatment in Boston will be watched with great interest, and it should receive a most careful consideration wherever plans for the benefit of the medical profession and for the advancement of medical knowledge are being matured.

The Boston Medical Library is especially indebted for its great progress to one man, Dr. James R. Chadwick, the librarian, whom Dr. Oliver Wendell Holmes described as the "untiring, imperturbable, tenacious, irrepressible, all-subduing agitator, who neither rested nor let others rest until the success of the library project was assured." Having pursued a cherished purpose for a quarter of a century the felicitations offered Dr. Chadwick at the dedicatory exercises will be echoed wherever interest in medicine lives.

Thanks to Dr. John S. Billings and the Index Catalogue, bibliographic research has been rendered comparatively easy and the scope of medical research greatly extended. The Index Catalogue has helped to create a demand for books and especially for periodicals. In the words of Osler, such men as Billings and Chadwick, "loving books partly for their contents, partly for the sake of the authors, they not alone keep alive the sentiment of historical continuity in the profession, but they *are the men who make possible such gatherings*" as the one in Boston the other evening. More men of this class are needed among us. When will the Billings and the Chadwick of some of the large cities west of the Alleghenies arise, in Chicago, in St. Louis, and elsewhere?

THE OPEN-AIR TREATMENT OF PULMONARY TUBERCULOSIS.

The knowledge that pure air is a potent agent in the cure, as well as in the prevention, of pulmonary tuberculosis is not a discovery of recent date, but it is only within the last quarter of the nineteenth century that the principle has been systematically applied. The fact must never be lost sight of that the tubercle bacillus is not the sole, though withal the specific, etiologic factor in the development of tuberculosis. The nebulous condition comprehended in the designation "susceptibility" constitutes only a less important factor. This may be inherited or acquired. It is best counteracted by hygienic measures and by improvement in the general nutrition; and these ends are best attained through a life in the open air and suitable dietetic regulations. It has been thought in the past that the first of these objects especially could be secured only at certain altitudes above sea-level and under certain meteorologic conditions present only in some localities; but the majority of sufferers from tuberculosis are unable for obvious reasons to leave their homes and assume the expense that change of residence necessarily entails. Fortunately for those who can not seek the desired climate, it is possible to provide them at home with many of its conditions, and the principal of which are purity of air and sunshine. These prophylactic measures are applicable also in the treatment of developed tuberculosis, and the success with which they have been credited commends their adoption in the largest number of cases.

Of the more general appreciation of the utility of the open-air treatment of pulmonary tuberculosis, evidence is afforded by the activity going on on many sides in providing means for its employment in the case of those unable from their own resources to secure its benefits. Governments and states, and other public bodies, are at present vying with one another in the laudable endeavor to make conditions easy for even the poorest tuberculous patient to avail himself of the advantages of the open-air treatment. Thus, in Pennsylvania a plan has recently been proposed by the forestry commisioner, Dr. J. T. Rothrock, having in contemplation the establishment of suitably located camps on the various forest reservations of the state, where tuberculous patients unable to provide themselves with a change of climate may spend several months in the year living in the open air. The first of these camps is to be established on a reservation in Clinton County, at an altitude of 2000 feet above sea-level, and having an area of 45,000 acres. Here it is proposed to erect large tents, with permanent foundations and anchorage, in order that they shall be as nearly as possible storm-proof. Each tent is to be provided with a heavy wooden floor, and separated by a distance of 15 feet from other tents. Along the front a covered wooden platform raised from the ground will be erected, so that the invalids need not be deprived of exercise on rainy days. The state is not to to be asked to contribute any money for the enterprise, as enough funds have been subscribed to meet the necessary outlay. The patients will be expected to provide their own means of subsistence. They will be required to adhere rigidly to the fish and game laws, and all laws for the preservation of forests, including precautions in the use of fire. Should the plan be successful, a second camp will be established in Dauphin County, overlooking the Lykens Valley, at an elevation of 1400 feet. Ultimately it is hoped to establish similar camps on every healthy forest reservation of the state.

The plan outlined is one to be commended. It is worthy of imitation, and on its merits is deserving of success. It will provide the means, otherwise unattainable, for restoring to health and usefulness a considerable number of victims of a disease recovery from which is yearly becoming more hopeful. Pulmonary tuberculosis should no longer be designated "consumption," as it is merely one of a number of acute infectious diseases capable of prevention, amenable to intelligent treatment, and susceptible of cure.

ANTIVISECTIONISTS AND MISREPRESENTATION.

Dr. Keen's letter, published in our last issue, ought to give a quietus—but it probably will not—to the blatant individuals who, with all their self-righteousness, have, as he shows, descended to the meanest arts of misrepresentation. The antivivisectionists have had their say uncontradicted so long that they apparently felt that their license to misrepresent was unlimited, and that they did not need to respect the ordinary rules of morality, more especially the ninth commandment. The welfare of the brute creation is their holy cause, judging from their average literature, but their diversion into philanthropy by raising the bogey of human vivisection has resulted disastrously. Dr. Keen certainly dissects their statements unsparingly, supporting by the most positive facts his charges of indefiniteness and garbling in their evidence before the Senate committee. Whatever may have been the personal responsibility of the president of the humane society for the facts as shown up by Dr. Keen, he ought to feel deeply humiliated at the exposure he has thus brought upon himself and the society he represents. It will stand on record, however, and no amount of abuse or further falsifying will alter or obscure the evidence of their disreputable methods. It is a pity that the cause of humanity to the lower creatures should be so encumbered with extremists who see nothing beyond the immediate objects of their solicitude, and unscrupulous advocates who do not hesitate to bear false witness against their neighbors. The medical profession is the humane one *par excellence*, but its first regards are for the welfare of humanity and it does not exalt the welfare of the brute over that of mankind.

THE DUTY OF THE PHYSICIAN TO THE STATE.

The recent utterance of a Philadelphia judge to the effect that it would be better that a patient should die rather than that a physician should neglect a judicial summons, has stirred up the lawyers as well as the doctors. The physician's standpoint has already been given editorially in The Journal,[1] but it may be of interest to note how it is viewed by the legal profession. The *New Orleans Times-Democrat* has taken the trouble to obtain the opinion of a number of leading members of the bar and judges upon the course of the judge, and their unanimity in condemnation of the opinion is striking. The expressions, "unreasonable and arbitrary," "not ruled by the ordinary law of common sense," "absurd," "inhuman," "brutal in its effects," are some indications of how the judge's action and statements are appreciated by his legal brethren. If he is at all sensitive to public opinion he will not be likely to repeat his action, which one can hardly believe was prompted by any deliberate consideration of the facts. Judges, however, are the men who, more than others, should guard their speech and action from any suspicion of inconsiderateness, and if they make mistakes such as that of this Philadelphia jurist, must suffer for it accordingly in public and professional estimation.

THE X-RAY IN QUACKERY.

It is a little remarkable that so striking a discovery, and one that impresses itself so strongly on the popular imagination as does the x-ray should have been left so long unutilized by the quack. This perhaps is due in part to the fact that some knowledge of the scientific side of electricity is supposed to be required, the Crookes' tubes and other apparatus being a little above the intelligence of the average charlatan, and in part to the fact that the regular profession has progressed so rapidly in discovering its remedial and diagnostic utilities that the quacks could not well keep up to them. This state of things, however, can not be expected to last, and now we have advertising specialists proclaiming the special advantages of the x-ray apparatus in their hands for modest females, enabling them to be examined without disrobing or otherwise exposing themselves. A comic paper in the early days of the x-rays contained a picture of a couple of skeletons, one sitting in the other's lap, worked up with all the expression of which these ground plans of humanity "far too naked to be shamed," are capable by the limner's art, but the aforesaid specialist's particular method of utilizing Roentgen's discovery strikes us as novel and entertaining. Still, perhaps the wonder is that it had not been thought of before, for the buzz and the blue flames with brass and glass accessories would go far to create the mental impressions desired by the quack, and the unquestioned scientific associations of the methods would help to increase his victim's confidence. We may probably expect to hear more from time to time of this discovery as employed as an adjunct to quackery, for which in several respects it has a peculiarly happy adaptability.

---

[1] February 9, p. 387.

MEDICAL ANARCHY IN TEXAS.

The fact that a Texas decision made all diplomas of whatever character qualifications for practice, has already been noticed in The Journal. This places Texas in about the lowest grade among the states, but it seems still lower depths can be reached. The *Texas Medical News* for January publishes a letter, received by a medical student in Galveston, in which the writer says he has a friend on one of the state boards of medical examiners who informs him "that one of the other state boards is clandestinely advertising. for applicants for license and assuring them of same if they will only appear before said board. And because of this. this friend of mine says to me: 'You offer license to any worthy and competent young man that you may find and I will furnish same.' So, doctor, if you desire a permanent state license for the practice of medicine and are willing to pay $25 for them, why, you can write me." The writer goes on to say that the offer is "no humbug, but good goods," that he is a regular practicing physician, etc., and to ask that it be treated confidentially and if a license is not wanted to have nothing said about it. As a commentary the *Texas Medical News* reproduces a clipping taken from the *Dallas News* of a recent date, giving an account of twenty-seven young medical students from a Memphis college. all Texans, passing the district medical examiners in Texarkana, some of whom returned to finish their studies while others proceeded at once to their homes to hang out their shingles without further preliminaries. A diploma-mill of the Armstrong type has heretofore been our ideal of the extreme of degradation of medical qualifications, but a district examining board of Texas, appointed by the district judges, selling licenses to practice at $15 to $20 a piece, goes it one better. Between the quacks and their legal friends and sponsors there would seem to have been, up to date, pretty nearly medical anarchy in Texas. The medical practice act just passed (see Medical News column) was certainly badly needed.

SAN FRANCISCO AND THE PLAGUE INVESTIGATION.

The Journal has referred to the plague in San Francisco on several occasions, and some of our readers may think we are too insistent in expressing our views in regard to what may seem of local interest. An apology is not needed, however, as the question is one not only of national but of world-wide importance. There has been much opposition to the efforts of the Government representatives—those connected with the U. S. Marine-Hospital Service—by the newspapers of San Francisco and, we are sorry to say, by a few medical men, and the Government decided to send a commission to investigate and report on the conditions found. The men selected for this commission are those whose ability, honesty, and scientific judgment are above criticism, representing three great medical centers, and, moreover, well known to the profession generally throughout the country. Their testimony will be held conclusive, whatever their verdict may be. Of the members of the commission, Drs. Barker of Chicago, and Flexner of Philadelphia, have already made a study of the plague in the Orient, having been sent to Hongkong and Manila for the special purpose of studying the diseases there prevalent. Their well-known scientific attainments made them especially prominent and no better selection could have been made by the Secretary of the Treasury. Dr. Novy of Ann Arbor, the third member, has long been one of the leading authorities on bacteria and toxins in this country, and his opinion will carry equal weight. According to reports, the members of the commission have already attended the autopsies of not less than six fatal cases of plague that have occurred since their arrival on the Pacific Coast, and one of these, it is further stated, was under observation by them four days before death. We also learn that for a short time it was feared one of the members of the commission had been infected from these cases, but this has fortunately turned out not to be a fact. Thus far the members have neither collectively nor individually given utterance to any data or opinions publicly or privately, but the above data were obtained from other reliable sources. The report, when it appears, will settle the question as to the existence of plague in California.

THE TOXICITY OF NORMAL URINE.

The significance of reports as to the toxicity of the urine in the presence of various morbid states will be great or little accordingly as the urine may possess toxic properties or not under conditions of apparent health. Clinicians have at different times sought to estimate the gravity of a number of diseases from a study of the toxicity of the urine, although it has been pointed out that normal urine also may be capable of injurious effects. In explanation of the latter, it has been suggested that they may be due to suspended solid elements, to the products of fermentation and to the presence of potassium salts. With the object of determining the degree of toxicity possessed by normal urine, as well as the nature of the responsible substance or substances, Dresbach[1] collected the urine, usually to the amount of four liters, from healthy adults, who were not and never had been users of tobacco, and prepared an extract, which was injected in concentrated watery solution into white mice in doses varying from 3 to 7 minims. The smaller amounts gave rise to somnolence, spasmodic movements and clonic convulsions, irregularity and difficulty in breathing, exophthalmos, dilatation of the arterioles, exaggeration followed by abolition of the reflexes, while large amounts caused death. On evaporating the extract to dryness, considerable residue remained, but this could easily be destroyed by heat, leaving practically no ash. It was thus shown that no mineral matter was present. Tests for xanthin compounds likewise yielded negative results. It is pointed out that the results produced could not have been due to potassium salts or to any organic substance usually included in the list of substances in normal urine.

---

[1] Jour. of Exp. Med., Dec. 15, 1900, p. 315.

THE HEREDITARY TRANSMISSION OF NEUROSES.

However heredity may act in the transmission of certain textural or nutritional disorders, or proclivities thereto, there can be no doubt of the fact that it does so act. It is true that disease may be conveyed directly from the mother to the fetus *in utero* through the placental circulation, but such a manifestation is in no sense an expression of hereditary transmission. Clinically speaking, it is not disease per se that is transmitted by heredity, but rather the morbid condition of tissue that either underlies or predisposes to disease—and this, it is to be presumed, is specific in the individual instance. In no class of affections is the influence of heredity as an etiologic factor more conspicuous than in the diseases of the nervous system, and especially the psychoses and neuroses; and this fact points the way to certain prophylactic possibilities. Thus, epilepsy, particularly if of the so-called idiopathic type, is often of distinctly hereditary origin, and the adoption of rational and practicable measures looking to the restriction of marriages and procreation by the unfortunate victims of this disease would aid materially in limiting its prevalence. Such measures must depend for their enforcement largely on the intelligence and self-control of the community rather than on arbitrary and rigorous legislation. An instance illustrating the pernicious influence on the offspring of epilepsy in the parent is cited by Bourneville and Poulard in *Progrès Médical* for September 29. A young married man in whom, without obvious cause, epileptic seizures began in the 30th year, begot eight children, two of whom died of athrepsia and one of cholera infantum. Of the remaining five, one was the subject of petit mal and of violent outbreaks of bad temper; another was the subject of grand mal, with hallucinations of vision and disturbances of sleep; and one was neurotic and suffered from night-terrors. From a consideration of cases like the foregoing, which are by no means isolated, it is not surprising that the authors reach the conclusion that marriage on the part of the subjects of epilepsy and epileptoid psychoses and neuroses should be forbidden or strongly discouraged.

THE INFLUENCE OF BACTERIA IN THROMBOSIS.

Thrombosis, especially of veins, is a not infrequent complication of infectious diseases such as pneumonia, typhoid fever, puerperal and other pyemic diseases. Thrombosis is also seen in so-called marantic states, in which death is often hastened by terminal infections. Welch, in his article on "Venous Thrombosis in Cardiac Thrombosis,"[1] states that micro-organisms have been found in a large number of thrombi in cases examined in his laboratory. There seems to be but little experimental evidence in favor of the infectious nature of thrombosis under these conditions. The recent work of Jakowski,[2] however, is quite suggestive. He injected sterile cultures or solutions of toxins of typhoid and of diphtheria bacilli into the circulatory blood of rabbits and guinea-pigs. After the injection a rubber band was placed around an extremity or an ear for one hour and then removed. Suitable control experiments were made and the animals killed twenty-four to seventy-two hours after the injection. Thrombi were not found in the control experiments in which bacteria or toxins were injected without compression of the vessels or in which compression was made without injection. In those experiments in which injection and compression were made clots were found constantly after the introduction of typhoid bacilli, but not so definitely after injection of typhoid *toxin*; living diphtheria bacilli were injected in these cases and in two thrombi were found after compression, but diphtheria toxin gave negative results. In a previous set of experiments with bacillus coli communis thrombi developed quite freely. Presumably the bacteria injected become implanted on the intima at the site of the compression, and multiplying they produce toxins that lead to the precipitation of fibrin. When toxins alone are injected the dilution becomes so great that they have no effect. To what extent these results are applicable to human pathology is uncertain, but surely they are suggestive. The exact manner in which bacteria induce thrombus formation will remain unknown until the chemistry and physics of coagulation are understood more clearly than now.

Medical News.

CALIFORNIA.

An osteopath of Santa Cruz, has been released from jail on a bond of $500, on condition that he leave the state.

The medical bill has been passed by the senate and will now, unless unforeseen-contingencies arise, become a law.

The health bill, which appropriates $100,000 as an emergency fund to be at the disposal of the governor and State Board of Health, to be used in case of emergency, has passed both the house and senate and will become a law.

Mary's Help Hospital is to be built on a large plat of ground on Guerrero street, San Francisco. The building will be for the exclusive use of women and children. The late Mrs. Kate Johnston left a bequest of $250,000 for the erection. equipment and maintenance of the hospital.

DELAWARE.

The Delaware State Hospital, at Farnhurst, has been granted an appropriation of $20,000 to cover the deficiency of $17,000 reported by the trustees and to provide for current unpaid bills.

Bills have been read and referred in the house of representatives, establishing a bacteriologic and pathologic laboratory at Delaware College, and extending the powers of the State Board of Health.

The Delaware Hospital, Wilmington, will open its new building in a short time. Its trustees announce that they have raised $21,657 of the $39,600 required to erect and equip the building, and make an appeal to the people of the state to contribute the $18,000 deficit, that the hospital may be free from debt when its new building is opened.

An amendment to the laws governing the admission and practice of physicians has been introduced by Senator Abbott, providing that whenever a physician who is a resident of the state and who was duly qualified to vote for representatives in the general assembly at the last general election prior to his application shall apply to the State Board of Medical Examiners for a certificate, it shall grant it without examination upon his presenting to the board a diploma from a reputable medical college, and on satisfactory proof that he had been in active practice of his profession at least ten years in any other state of the United States.

ILLINOIS.

The Rockford City Council has decided that physicians charge too much and so has cut down bills presented to it from 27 to 40 per cent.

Consumption has decreased in the state penitentiary at Joliet, so that, while in 1895 thirty-nine deaths were reported as due to this disease, in 1900 only eight occurred. This appears to be due directly to the segregation of tuberculous patients.

---

[1] Trans. Am. Assn. of Phys., 1900, xiv.

[2] Centralbl. f. Bact., 1900, xxviii, 801-809.

A state sanatorium for tuberculosis is provided for in a bill recently introduced in the lower house. The bill was framed by Dr. John A. Robison, Chicago, and is endorsed by the Illinois State Medical Society, the Illinois Society for the Prevention of Consumption, and the State Board of Health. It appropriates $200,000 for the purchase of a site, erection of a building, and maintenance for one year.

Chicago.

Chicago's mortality for the week ended February 23 was 511, or an annual death-rate per 1000 of 15.68. Of the deaths, 172 were due to diseases of the respiratory system, and 26 to violence.

Dr. S. Cecil Stanton has just received an appointment of contract surgeon in the United States Army, to be stationed in Chicago. Dr. Stanton has been doing work in connection with the government's recruiting station here for some time.

The indictments against Dr. August M. Unger, in connection with the life insurance case of Miss Marie Defenbach, which he sought to have quashed, will stand, as Judge Holdom, on February 21, overruled the motions to quash in each of nine counts in each of three indictments.

The smallpox situation is improving; 10 new cases were discovered last week as against 17 the week before. The total up to February 23 is 27, with no death; 13 have been discharged from the isolation hospital, and 33 remain under treatment. The prompt discovery and isolation of cases and the wholesale vaccination of the exposed neighborhoods are relied upon to keep the disease under control.

The health department has issued a warning that debilitating causes of all kinds—alcoholism especially—predispose to attacks of pneumonia. Exposure to sudden changes of temperature should be avoided; the feet kept dry and warm and the throat and chest well protected; fasting rather than indulgence should be observed. The higher the bodily condition the less favorable is the growth and virulence of the pneumonia germ. The laboratory examinations show a notable decrease in the findings of the influenza bacillus, indicating that the disease is declining; on the other hand, the organism of pneumonia is found in increasing numbers and there is a strong probability that, with the usually trying March weather, there will be a marked increase in the prevalence of this malady.

INDIANA.

St. Margaret's Hospital Staff was organized February 15, with the following officers: Dr. James T. Clark, president; Dr. Cyrus W. Campbell, vice-president, and Dr. H. Edgar Shanes, secretary.

The faith-curers sustained a serious reverse February 19, when the senate voted to accept a favorable report on Senator Wood's bill requiring believers in faith cure to call medical aid in the illness of children and dependents. The bill makes it a felony to withhold medical aid from children and other dependents when such dependents die for the lack of medical aid.

KANSAS.

Dr. Ralph C. Henderson, Erie, has been appointed pension-examining surgeon at that place.

Sherman County has quarantined against Norton, Almena, Sharon Springs and all other towns infected with smallpox, until further orders.

Dr. Irwin E. Bennett, U. S. A., formerly of Leavenworth, has been promoted to a captaincy in the medical department. He is now on duty with the United States forces in China.

MICHIGAN.

The Lansing Hospital Staff has been organized with Dr. Rush J. Shank, president, and Dr. L. Anna Ballard, secretary.

Dr. Harry B. Britton, Ypsilanti, has been appointed a member of the board of medical pension examiners, to succeed Dr. Frank K. Owen.

MINNESOTA.

Dr. George H. Overholt, Kenyon, has been appointed health officer and placed in charge of the smallpox cases in Holden.

Daily inspection of the public schools of Minneapolis has been inaugurated, and a staff of fifty medical inspectors has been appointed to carry on the work.

Dr. Geo. D. Haggard, Minneapolis, Minn., has presented a number of wax and plaster models of smallpox eruptions to the medical department of the University of Minnesota.

After the Quacks.—According to the *Northwestern Lancet*, the Minnesota State Board of Medical Examiners has recently done good work in Minneapolis, in suppressing quackery. Two local advertising quacks have been obliged to discontinue their practice, at least under their own names. A third, not a physician, but representing himself as one, has been bound over to the grand jury.

Proposed Legislation.—A bill endorsed by the state medical society has been introduced, providing for a state board of medical examiners of twelve members, to be appointed by the governor from the different schools of medicine. The board can dispense with examinations in cases of practitioners authorized to practice in other states, or their payment of a $50 fee, when moving into Minnesota, provided said states demand qualifications of equal grade with Minnesota and extend the same privileges to practitioners holding Minnesota licenses.

NEW JERSEY.

Dr. Paul Mecroy, of Camden, has been appointed physician and surgeon of the Pennsylvania Railroad, to succeed Dr. Dowling Benjamin.

Christ Hospital's council and staff gave a dinner to Dr. John A. Robinson, retiring house-surgeon, in the sun parlors of the hospital, Jersey City, February 14.

The State Board of Health is forcing New York physicians who practice on the west side of the North River, to register and obtain license to practice in New Jersey.

NEW YORK.

Dr. Clarence V. Gray has been appointed health officer of Elba.

Dr. Harriet M. Watson has been appointed resident physician at the Albion House of Refuge.

The Binghamton health board has passed a resolution that houses where typhoid fever or measles exist shall not hereafter be placarded.

A bill has been introduced in the Assembly to provide for sending indigent persons requiring medical attention to the nearest hospital approved by the State Board of Charities.

Dr. Patrick J. Barrett, Utica, has been placed in charge of the isolation hospital, and Dr. Fred J. Douglas has been appointed city health officer vice Dr. Wallace Clarke.

The bill to abolish the State Board of Health, and substitute a single commissioner, is now before the governor. The commissioner is to be appointed by the governor at a salary of $3500.

Dr. Charles H. Andrews, Bergen, has been promoted to captain in the medical department of the army, and appointed a member of the examining board at San Francisco to examine volunteers preliminary to muster-out.

Regulation of Sale of Poisons.—A new state law places greater restrictions on the sale of poisons than were ever specified by any other measure. No substance which, in the words of the law, "according to standard works on medicine or materia medica, is liable to be destructive to human life in quantities of 60 grains or less, shall be sold at retail or furnished without being labeled with the name of the article and the word 'poison' and the name and place of business of the seller plainly printed in red ink." A record must be kept of the more dangerous poisons, as arsenic, cyanid of potassium, hydrocyanic acid, cocain, morphin, strychnin, and all other vegetable alkaloids and their salts. A complete record, including the name of the purchaser, his address, the amount of poison sold and date of sale, must be kept where it can be inspected at any time by the proper authorities, and must be preserved for five years.

Buffalo.

Dr. Nelson G. Russell has been selected assistant surgeon of the 65th Regiment.

The board of health has prepared an ordinance against expectoration in cars and public places, and also one providing that bottles used for milk shall not be used for other purposes.

The department of health report for January shows the death-rate per 1000 to be 18.08. Of the 531 deaths, 83 were from communicable diseases. The total deaths for January were 531, as compared with 437 in January 1900.

New Consumption Hospital.—Ground has been broken for the consumption hospital on the Erie County Almshouse grounds, which is to replace the former structure burned last March. The cost of the building is to be $50,000.

The ninth annual report of the Charity Eye, Ear and Throat Hospital of Erie County shows 1983 new cases treated during the year. The hospital authorities are well pleased with the workings of the new law which makes it a misdemeanor to obtain treatment under false pretenses.

New York City.

Dr. Edith B. Blackwell has been appointed resident physician and teacher of physiology in the State Normal School at Greensboro, N. C.

The New York Skin and Cancer Hospital has received a second donation of $5000 from Miss Emily S. Watson, New York, to endow a free bed.

The Montefiore Home for Chronic Invalids has changed its name to the Montefiore Hospital, because the latter name more accurately describes the function of the institution, whereas its former title had led many persons to suppose that it was a permanent residence for invalids.

Clinical Lectures on Syphilis.—The New York Skin and Cancer Hospital announces a course of clinical lectures on Syphilis, by members of the visiting and consulting staffs, on Wednesdays during March and April, and May 1. The lecturers are Drs. L. Duncan Bulkley, Abraham Jacobi, D. Bryson Delavan, David Webster, Edward D. Fisher, Edward G. Janeway, and Willy Meyer. These lectures are free to members of the medical profession on presentation of their professional cards.

Smallpox.—During the past week between 20 and 30 new cases of smallpox have been reported from widely separated sections of the city, 13 in one day; and 3 with the disease far advanced, walked into the Harlem Hospital in the course of three hours. The Health Department has issued a statement calling the attention of the public to the fact that the disease is not abating, and that they are now only vaccinating about 30 persons daily whereas, a few weeks ago, the daily average was 2000.

OHIO.

The Arcadia Board of Health has been organized with Drs. Madison G. Baldwin and Robert B. Taylor as its medical members.

Dr. Frederick C. Jackson, formerly of Columbus, now an acting-assistant surgeon in the Army, on duty in the Philippines, has been made captain and assistant surgeon of volunteers.

A fire broke out in the kitchen of the Cincinnati Hospital, February 19, and for a time threatened the destruction of the entire building. In the attempt to put it out several of the hospital employees were severely burned.

The Divine Healer.—The case of "Dr." Yaeger, which, as mentioned in THE JOURNAL of last week, was continued for a week, came up in Squire Winkler's court, Cincinnati, February 23. She was bound over to await the action of the grand jury for practising medicine without a license, and was released on her own recognizance of $500.

PENNSYLVANIA.

Smallpox has been reported during the last week in eight localities in the state.

Measles is prevalent in Cambridge Springs, and up to this time about one hundred cases have been reported.

New Hospital for Allegheny.—The Allegheny General Hospital will probably be soon supplanted by a new institution to cost about $350,000. Already $180,000 has been subscribed and the state will be asked to give $100,000.

Philadelphia.

The Administration Building of St. Timothy's Hospital, Roxborough, was damaged by fire and water to the extent of $2000.

The public baths of the city were patronized during the past year by 108,000 persons; there was a net deficit for the year amounting to $1,481.89.

Quiz Course.—The Medico-Chirurgical College announces a special quiz course for the preparation of candidates for the medical corps of the United States Army, Navy and Marine-Hospital services and for state board and hospital examinations.

Rush Hospital for Consumption held its annual meeting February 19, and plans were announced for a considerable enlargement to the facilities offered by that institution. The number of cases treated during the past year was the largest since the hospital was opened.

TEXAS.

The medical examining board of the eighth judicial district has elected Dr. Joseph D. Beckton, Greenville, president, and Dr. Robert L. Combs, Cooper, secretary.

A committee from the legislature has gone to Galveston to investigate and report on the needs of the state medical college at that place. The board of regents has asked for an appropriation of $60,000 to restore the college buildings which were damaged by the storm, and of $45,000 for the maintenance of the institution.

GENERAL.

Medical Officers' Association.—The annual meeting of the Association of Medical Officers of the Army and Navy of the Confederacy is to be held at Memphis, Tenn., May 28 to 30. All surgeons, assistant surgeons, acting-assistant surgeons or contract physicians and hospital stewards of the army and navy of the Confederate states, and all regular physicians who served honorably in any capacity in the confederate army and navy, and all regular physicians who are sons of confederate veterans are eligible to membership. Dr. A. L. Elcan, Memphis, Tenn., is the secretary.

Practice in Texas.—A medical practice act has just been passed by the legislature and approved by the governor. It repeals all previous laws and establishes three boards of medical examiners to be appointed by the governor on the recommendation of the state medical societies of the regular, homeopathic and eclectic schools. These boards, which shall contain nine members each, shall meet regularly twice a year at certain definite times and places, due notice being given, and examine all persons making application for licenses for practice. The examinations will include the following branches: anatomy physiology, chemistry, materia medica, histology, pathology, practice of medicine, surgery, diseases of the eye, ear, nose and throat, obstetrics, gynecology, hygiene and medical jurisprudence. The application must be in writing and accompanied with a fee of $15, excepting where it is simply for the practice of midwifery, where the fee shall be $5. A diploma from a satisfactory source is a requisite, the boards apparently being the judges as to its merits. The funds realized by the fees shall go toward the payment of the necessary expenses of the boards of examiners, each board receiving such fees from applicants who appear before it. The exceptions to the provisions of this act are: all those who began practice of medicine in the state prior to Jan. 1, 1885, and all those who began practice since that time, and who have complied with the state laws in effect prior to the passing of this act, provided that those who have diplomas recorded since January, 1891, shall present to said boards of medical examiners satisfactory evidence that their diplomas were issued by a bona-fide college of respectable standard. The law contains a clause providing that newcomers in the state, who have licenses granted by another state board of medical examiners, properly certified and showing that the standard of the requirements of the medical laws of said state or territory are equal to those provided by this act, shall also be permitted to practice on payment of the usual fees. Any person shall be regarded as practicing medicine or surgery within the meaning of the act who shall profess the pursuit of a physician or surgeon and shall offer for practice, as such, for those needing medical or surgical aid and shall charge money or other compensation. The act shall be construed to include persons not pretending to be physicians, who offer for sale publicly on the streets remedies not manufactured and compounded within the state, which they recommend for the cure of disease. The provisions of the act do not apply to persons treating diseases, who do not prescribe or give drugs or medicine. The law, therefore, unfortunately leaves a large gap for osteopaths, "Christian scientists," and all that sort of quackery.

CANADA.

The Tuberculin Test.

Professor Adami, of McGill, Montreal, who has always taken a lively interest in the subject of the tuberculin test, considers it unfortunate that the breeders throughout Canada should be advocating the repeal of the legislation concerning the employment of this test in cattle. He considers the test an absolute necessity for safety in that high-bred herds, by reason of their perpetual inbreeding, are very liable to tuberculosis. A large proportion of the pedigree cattle of England are affected, and against them the Argentine Republic has issued prohibitive legislation and the United States has imposed very severe quarantine regulations. Certain breeders in Canada are thus trying to evade the American reuglations by bringing in cattle from England and then exporting them across the line as

Canadian bred and born cattle. Dr. Adami considers this would be a most retrograde step if Canada would cease employing the tuberculin test, a test which is steadily growing in favor in England, France and Germany. He further considers that the alarm concerning the finding of the tubercle bacillus in one of Koch's preparations, tuberculin R., is misplaced, and that the fear of the cattle men may be set at rest as the manufacture of this product has been so modified lately as to make the survival of the bacillus an utter impossibility; and then tuberculin R. is too expensive to be employed on cattle, being reserved for the treatment of human beings alone.

The Asylums of Quebec.

The last annual report of the Asylums of the province of Quebec has been laid on the table of the legislative assembly now in session. This gives the total population of the asylums of that province, in the year 1899, as 2981, and the cost of maintenance $314,157.48, both figures showing an increase over those of 1898. The three principal asylums are now in a satisfactory condition. They are the Quebec City Asylum, the Verdun Institute and the Longue Pointe Asylum. It is noticed that the percentage of cures has been somewhat less than for the previous year. In the Quebec asylum for 1898, it was 41.62; for 1899, 31.75; Verdun, 1898, 43.63; 1899, 33.33; Longue Pointe, 1898, 27.35; 1899, 25.8.

Montreal General Hospital.

The medical superintendent's report showed that 667 patient's were treated to a conclusion during the past quarter. Of these 64 died, or 9.5 per cent. If the number who died within three days of their admission to the hospital were deduced the mortality would be reduced to 5.7 per cent. The daily average number for the quarter was 180, and the average detention 23.5 days. In the out-door department there were 10,733 consultations, an increase of 1,352 over the corresponding quarter of 1900. The financial position of the institution has not been good for some time back; and a proposal was made at the meeting to charge every patient at the out-door department five cents for medicine. The committee of management will look into this matter and report at a later date.

Montreal Civic Hospital.

So repeated and bitter have been the attacks on the condition of the contagious disease hospital, both from prominent medical men of the city and the citizens in general, that the medical superintendent, Dr. Laberge, and the lady superintendent have intimated their intention of resigning. The chairman of Montreal's hygienic committee has been most energetic in trying to secure appropriations for a new institution, but there seems to be a deadlock between the French and English sections in council as to whether one combined hospital for both nationalities or a dual system be adopted.

"Christian Science."

An investigation was recently held in Peterborough, Ont., into a case of death from typhoid fever under treatment by the "Christian Scientists"; an another in Victoria, B.C., on the death of a child from laryngeal diphtheria. In both instances strong verdicts were returned by the coroners' juries, condemning the practices of "Christian Scientists," verdicts which are healthy indications that the public is awakening to the danger of allowing these people to continue endangering the health of the community from disregard of isolation in communicable diseases.

LONDON.

Outbreak of Typhus Fever in Manchester.

A remarkable outbreak of typhus fever has taken place in Manchester, a city from which the disease has been absent for many years. On December 31, two young women were admitted to the hospital suffering from typhoid fever. Five days later two girls were admitted, one suffering from typhoid and the other from typhus fever, and on January 8 a third couple suffering from typhus fever. It was then discovered that all these girls worked at the same establishment—a rag-sorting warehouse. A remarkable feature was that all the persons attacked were engaged in the woolen-rag department, not one in the cotton department being affected. Nearly all the girls live in Ancoats, one of the slums of Manchester, in great dirt and poverty. The source from which the rags were infected can not be discovered. As the disease was not discovered before the patients came in contact with others, there are now thirty cases in the hospitals. One girls seems to have communicated the disease to seven persons. On visiting her home, the medical officer of health, being unable to gain admittance, forced an entrance and found the father and two children in bed, all too ill with typhus to help themselves. Three deaths have already taken place. All the rags have been disinfected, besides the workrooms and houses of the patients.

The Late Queen and the Medical Profession.

Among the universal tributes of loyalty and affection evoked by the death of the queen, those which have come from the medical profession are not wanting in fervency. Her late majesty was always on excellent terms with the profession. whose services she valued highly. At the meeting of the Royal Medical and Chirurgical Society, of which the queen was patron, a loyal address of sympathy and homage to the king was adopted. The president, Dr. F. W. Pary, said that the Society was instituted about a century ago, for the cultivation of medicine and surgery. In approval of its laudable design it received a charter of incorporation from William IV., in which the king declared himself and his successors, if they should think fit, a patron of the Society. The queen followed in his footsteps. Lord Lister, in moving the adoption of the address, said that his was an inexpressibly melancholy honor. The medical profession, whose object is to prevent or relieve the physical ills of mankind, appealed always to her majesty's warm and sympathetic heart, and the profession never had a more loyal friend. All her medical attendants, if alive to-day, would speak with one voice. Nothing could be more striking than her complete confidence in her medical advisers and her submission to chloroform at a time when its use in midwifery was by no means generally recognized and in influential quarters opposed. Lord Lister said that he believed he was the only person who ever exercised on the queen the art of surgery. The occasion was a most critical and anxious one, but while she treated him with queenly dignity, nothing could exceed her kindness. The king has shown, during the past fortnight, that he inherited the grace and tact of the departed sovereign. He always honored and loved the medical profession. Witness all that he had done for Guy's Hospital, and the prosperity of the Prince of Wales' Hospital Fund, in which he took the keenest interest!

FOREIGN.

The antidiphtheria serum prepared in Milan, and recently referred to in these columns as having caused tetanus infection, has been collected in the laboratories of the Superior Council of Health and is to be submitted to experimental tests.

Collection Burned.—A fire in the old portion of the Pathological Institute at Berlin destroyed a cabinet of collections belonging to Virchow. The articles that were saved lost their labels, and Virchow mourns the irreparable loss to himself and to science of this collection of anthropologic and prehistoric relics.

Women as Internes.—A French medical woman has passed the competitive examination and has been accepted as an interne in the Paris hospitals. In 1886 Miss Klumpke was appointed "titular" interne, and five other young women have since been made "provisional" internes. The hospitals of Bordeaux and Rouen have also had women internes.

Deaths.—Dr. G. R. von Hochberger, of Carlsbad, died February 4, in his ninety-ninth year. He had been the recipient of many honors in his long and useful life. The president of the St. Petersburg Military-Medical Academy, Professor V. Paschutin, died suddenly while presiding at a meeting of the faculty of the Academy.

Hygiene of Postoffice.—According to *The Lancet* of February 16, an inquiry into the hygienic condition of the postoffice employees in Paris, with special regard to the presence of tuberculosis, showed that this disease was responsible for 36 per cent. of the deaths among the members of the staff, this being a much higher rate than the general tuberculosis deathrate for all France.

Death of Pettenkofer.—The progress of hygiene during the last century owed much of its impetus to Max von Pettenkofer, M.D., of Munich, who, depressed by the inroads of an incurable disease, recently shot himself. He was in his eighty-fourth year, and had been one of the earliest collaborators on the *Muenchener Med. Woch.*, some of his articles dating from 1854. Many international honors had been bestowed upon him.

Endorsement of Company Physicians.—The sixty physicians connected with the Munich Sickness Insurance Company No. 4, refused to accept lower terms than those previously agreed upon, and appealed to the other members of the profession to sustain them in their course. Of the 530 physicians who received this appeal, 509 replied, formally agreeing to comply with the request of the subscribers. Most of the remaining twenty-one have nothing to do with this kind of practice, so the results show a practically unanimous endorsement of the company physicians.

Progress of the Plague.—According to *The Lancet*, February 16, the suspicion that a case of plague had occurred at Cardiff has been verified, and a crusade against rats inaugurated, the sum of fourpence being paid for every one caught within the borough or port-sanitary district. A similar effort to diminish the rats at Cape Town, South Africa, followed the reports of the disease having gained a foothold in that city. On February 15 the cable announced twelve cases in the hospitals there, with two deaths up to that date.

Medical Societies in Spain.—The Spanish government has resolved to thoroughly enforce the regulations enacted in 1898, that no physician is allowed to practice unless he has inscribed his name as a member of the local medical society. Each town of more than 14,000 inhabitants must organize one of these societies or academies of medicine, to promote the moral and material interests of the profession and give advice on questions submitted by the national or municipal authorities or courts. The *Sem. Méd.* states that they are already organized in a large number of towns.

Correspondence.

Dr. Nicholas Senn and the Louisiana State Board of Health.

New Orleans, La., Feb. 6, 1901.

To the Editor:—I have read with much interest the article of Dr. Nicholas Senn, in The Journal of January 19, entitled "Costa Rica, its Physicians and Medical Institutions." It reflects great credit on this universal writer, but he has been misinformed in regard to some of his statements concerning quarantine. All that comes from the pen of one of such standing as Dr. Senn carries so much weight that it is impossible for me to allow to pass unnoticed some statements which are not justified by the facts.

On page 185 he says: "The quarantine system at the Port of New Orleans is, however, too complicated. There are two quarantine stations under the jurisdiction of the State Board of Health, which often at a distance decides whether or not a vessel should be detained, which often gives rise to great confusion and not infrequently enforces unnecessary quarantine."

The truth is that there is but *one* board of health regulating quarantine, and that is the Louisiana State Board of Health. The board of health of the city of New Orleans has no right to quarantine under the present law, Act 192 of 1898. The state board is unique and supreme.

There are at the mouth of the Mississippi River two inspection stations. The first is at Port Eads, on the outlet of the South Pass, where a preliminary inspection is made and from which vessels with cases of contagious diseases are sent to the Lazaretto, several miles higher up on Pass a l'Outre. The second station is the famous Mississippi River quarantine station on the east bank of the river, some fifteen miles above Port Eads, where vessels are re-inspected, disinfected and detained.

The Louisiana State Board of Health never at a distance decides whether or not a vessel shall be detained. On April 1, of each year, quarantine is *proclaimed* against the South American, Central American and West Indian ports by the Gulf and South Atlantic ports of the United States. All vessels arriving at those American ports, from the above quarantined ones, are inspected, disinfected and detained from five to eight days. Fruit vessels bringing perishable cargoes are exempted from detention and are permitted to unload at the wharf under certain conditions, and as long as the Central American fruit ports are free from yellow fever; but as soon as the resident medical inspector of the Louisiana State Board reports the existence of yellow fever at any fruit port, these special privileges are withdrawn or are modified for that port.

Further on, on the same page, the eminent writer states: "The best solution of this important and difficult question would be to place the Port of New Orleans under the jurisdiction of the Marine-Hospital Service, etc."

This expression is most unfortunate, especially as coming so soon after the signal failure of the U. S. Marine-Hospital Service to recognize the existence of yellow fever in time, at Port Limon last year. That service admitted the existence of the fever there several weeks only after the distinguished representative of the Louisiana State Board of Health, Dr. Will H. Woods, had advised the board of the presence of the fever at Limon, and after cases had occurred on fruit vessels plying between that port, New Orleans and Mobile. Mobile was guided by the reports of the representative of the U. S. Marine-Hospital Service and escaped infection only by enforcing the most rigid measures. Although Mobile had not actually recognized Limon as infected, she treated vessels from there as if the port was infected. Finally, she did proclaim Limon infected.

No one can protect us better than we can do it ourselves. The fact is, the people at those ports are so indifferent as to sanitary matters and are so little afraid of yellow fever, that they believe all of our fears are exaggerated. The day that sanitation shall occupy in their minds and practices the high position it does with us, then all reliance may be placed on them and matters will be much improved. Yours truly,

Edmond Souchon, M.D.
President Louisiana State Board of Health.

The Case of Governor Goebel and Bloodless Work.

Bowling Green, Ky., Feb. 18, 1901.

To the Editor:—My attention has just been called to a paper in The Journal of the 9th instant, by Dr. Dawbarn, of New York City, on "The Technique of Bloodless Work," in which is contained the following paragraph, evidently intended by the author as a criticism of the treatment of the case of the late Governor Goebel: "A recent sensational murder in politics, in another state, produced a bit of most antiquated and archaic surgery—according to the newspapers and several medical journals, and the statement went uncontradicted. I allude to the fact that in order to try to stop the bleeding from his wounded lung the surgeon bled him a pint or more from his arm! This plan has antiquity to recommend it, but nothing else. He died of shock, *apparently*, and we all know that hemorrhage invites shock. Had the extremities promptly been corded effectively, accumulating venous blood in them, the ending might well have been a different one."

The above paragraph is untrue, and its publication in The Journal, under the name of a surgeon who claims to be reputable not only does me, but the excellent medical men who were associated with me in the case, a gross injustice. Governor Goebel was not only not bled, but such a procedure was never even suggested, and the report went uncontradicted because no such thing had been published to my knowledge and, had I seen such a publication, I would hardly have expected that any medical man would believe it from mere newspaper rumor. Nor was there at any time serious hemorrhage, practically none externally, only about eight ounces having been found in the pleural cavity after death.

Our patient was in profound shock at first, cold, pulseless and lifeless, but responded with reasonable promptness to the hot saline intravenous injections, heart stimulants and external warmth which were resorted to within a few minutes after he was shot. While the salt solution was running in, the wounds were carefully cleansed and a temporary dressing applied. The patient was in bad physical condition before he was shot. He was never a very robust man, had been under high nervous tension for months, and had an attack of acute indigestion, vomiting freely, before leaving the hotel that morning. Under all of these disadvantages he rallied and did well until the end of the fourth day, dying from a violent foreign-body pneumonia, the bullet having passed through all of his clothing before reaching his body. Drs. Vance, of Louisville, Barrow, of Lexington, and Dandridge, Walker and MacKenzie, of Cincinnati, all distinguished surgeons and teachers, saw the case a few hours after the injury, and were all kind enough to warmly commend the entire treatment, being especially complimentary as to the almost immediate resort to the use of the normal salt solution. You can imagine my surprise at having the treatment unhesitatingly condemned by a man some hundreds of miles away, who is and was as ignorant of what was actually indicated and done as he appears to be of the courtesies due between professional gentlemen.

Snap diagnoses and absent treatment have heretofore been confined to magnetic healers and "Christian Scientists," and this brief experience leads me to hope that such methods will never be adopted by reputable professional men. Very respectfully, J. N. McCormack, M.D.

Another Fraud Solicitor.

Chicago, Feb. 15, 1901.

To the Editor:—I learn that several physicians in Chicago have been victimized, as I was, recently by a scoundrel professing to be the representative of a newspaper subscription agency. I presume the firm which he professes to represent is a reputable one, although I wonder that they do not seem more interested in apprehending this man and prosecuting him, as he is not only collecting money in their name, but forging their signature to checks made out to the agency.

As the magazines for which I subscribed failed to make their appearance some weeks after the visit of this agent, I addressed a letter to Moore's Agency, and received the following reply:

> Your favor of the 14th received, and in reply would say we have no agent by the name of W. R. Neal, and we do not offer any such list of magazines as you mention for $4.00. This man is a fraud, and we have had a great many complaints in regard to him, as he is traveling around through different cities in the West and carrying on this scheme. We do not have any traveling representatives and never allow the agent to present a receipt in our name, as we have thought it liable to lead to some such system of fraud. We have been unable to locate this man as he travels around from place to place, and we do not hear in regard to him until he has left each locality. If you can find any way by which you can secure him we would advise you to take such steps at once. We regret very much that he should have misrepresented himself as our agent and that we are unable to help you out in the matter. Yours truly (signed), W. H. Moore.

As this fellow seems to have victimized a number of physicians in the city, I think it would be well to warn others through the columns of your journal. Very truly yours,

John M. Dodson, M.D.

Feeding in Typhoid Fever.

Boston, Feb. 19, 1901.

To the Editor:—It has been noticed in several cases of fever, especially typhoid, that a total change from an animal food element in diet, and substitution of only vegetable elements was followed by lessened fever, and consequently better sustained strength of the patient.

I am informed that the typhoid bacillus generally develops much more freely on animal culture material than on vegetable, with perhaps occasional exceptions.

Should it not, therefore, seem that the common practice of feeding fever patients with milk and meat juice and such elements as promote the increase of the bacillus and its toxins is simply feeding the fever and thereby weakening instead of sustaining the strength of the patient? A list of foods least promotive of growth of bacilli, also a list of those most promotive might be convenient for reference to the general practitioner. As an inhibitory medicine, harmless in proper doses, sulphite of soda has been thought to aid in retarding the development of bacilli and toxins. Jacob L. Williams, M.D.

Movable Kidney.

Brooklyn, N. Y., Feb. 19. 1901.

To the Editor:—I note with great pleasure, in The Journal of February 9, the paper entitled "Movable Kidney from the Standpoint of the General Practitioner," by Dr. Alexander Marcy, Jr. As these cases are very often of a neurasthenic type, I should like to suggest the employment of lupulin and sumbul combined with either the tincture or extract of nucis vomicæ. There can be no question of the permanent benefit derived from massage and hydrotherapy, properly carried out. Coming now to the local, or mechanical management of nephroptosis, permit me to again call attention to the plaster bandage described by me in the *Medical News* of Sept. 1, 1900, mentioned also by Rose in the *Post-Graduate* for March, 1900. This device is the most satisfactory in every way, of any form of abdominal support, which has come to my notice. It is inexpensive, easily adjusted, not bulky or in any way uncomfortable, and accomplishes its end far better than a ready-made bandage. The special pad for the displaced organ itself, I do not believe avails anything. In contradistinction to the view expressed in the paper under discussion, the above, and not surgical intervention, forms the best mode of treatment for "floating kidney."

The two formulæ I generally employ are the following: In cases in which there is a tendency to constipation: lupulin, 1 gr.; zinc phosphid, 1/16 gr.; sodium bromid, 2½ grs.; gelsemin, 1/20 gr.; arsenious acid, 1/20 gr. These I use, one after meals, and one before retiring. In other cases the following acts admirably: Lupulin, 5 gr. (equivalent to tr. valerian, 1 dram, tr. sumbul, 1 dram), asafetida, 3 gr.; ext. nucis vomicæ, 1/6 gr.; in tablets, taken the same as No. 1.

H. W. Lincoln, M.D.

Accidental Vaccination.

Meadow Creek, W. Va., Feb. 21, 1901.

To the Editor:—In the February number of *Medicine*, a case of vaccin infection was reported. I have seen a similar case. Some time last November a woman came to my office to show me a peculiar looking sore on her neck. I had recently vaccinated a number of persons, and, among them, three children in the family in which this woman was a nurse. On inquiry I found she had been scratched on the neck by one of the children, while taking care of it. She had never been vaccinated. The sore was a characteristic vaccination pustule. I was forced to the conclusion that the child had accidentally conveyed the vaccin from its arm to the neck of the nurse by its finger nails.

G. D. Lind, M.D.

Book Notices.

Diseases of the Intestines. A Text-Book for Practitioners and Students of Medicine. By Max Einhorn, M.D., Pages, 390. Price, $3.00. New York: Wm. Wood & Co.

This treatise is a continuation of the author's work on "Diseases of the Stomach," the two volumes thus covering the principal disorders of the digestive tract. The anatomy and physiology of the intestinal canal are briefly and clearly described. Methods of examination are discussed, but we find no mention of the elevated position so important in proctoscopy nor of the long tubular specula for use in examining the lower bowel. The introduction of the whole hand and arm into the rectum, according to Simon, should only be mentioned to be condemned as it is scarcely possible to conceive of a condition in which such a procedure would be necessary.

A duodenal ulcer is defined as "A defect in the mucous membrane of the duodenum." As a scar is as much a defect as an ulcer the definition is not a good one.

The definition of hemorrhoids is also incorrect, as it states that they are simply "varicose dilatations of the hemorrhoidal veins." A hemorrhoidal mass always consists of something more than varicose veins. There is an hyperplasia of connective tissue in addition to the varicosities. The changes are correctly described under "Morbid Anatomy," but the definition is imperfect.

Under the treatment of appendicitis we find these statements: "The use of cathartics is mentioned here only in order to condemn it." "The remedy *par excellence* in the treatment of appendicitis is opium." These are the views of an internist. In a recent work on appendicitis by a prominent surgeon of an unusually large experience, we find these statements, just reversed: "The most important feature of the treatment of a case of acute appendicitis is the prompt administration of a laxative—an effort should be made to secure at least several stools." "The administration of opium in the treatment of appendicitis can not be too strongly condemned." Such diametrically opposite statements by experienced observers must convince the ordinary man that the course of acute appendicitis is but little influenced by such medicinal treatment. That patient with appendicitis is best off who is soonest rid of his inflamed appendix.

The several varieties of acute intestinal obstruction are clearly described, and the importance of early surgical treatment strongly urged. A very interesting chapter is that on the intestinal neuroses. The volume closes with a chapter on the intestinal parasites. The work, as a whole, is a good one. The author has had a large experience, and writes knowingly of his subjects. The work is also unique in the fact that it is practically the only monograph on the diseases of the intestine in the English language. The practitioner will find in it much useful information.

The American Year-Book of Medicine and Surgery for 1901. A Yearly Digest of Scientific Progress and Authoritative Opinion in all branches of Medicine and Surgery. drawn from journals, monographs, and text-books, of the leading American and foreign authors and investigators. Arranged with critical editorial comments, by eminent American specialists. In two volumes—Volume I, including *General Medicine*, Octavo, 681 pages, illustrated; Volume II, *General Surgery*, Octavo, 610 pages, illustrated. Cloth, $3.00 net; Half Morocco, $3.75 net. Philadelphia and London: W. B. Saunders & Co. 1901.

The advance being made in the various departments of medical science is so rapid that it is practically impossible for one to keep up in the various branches of medicine. In fact, it is no easy matter to follow the literature, in one, much less all. There are workers in all fields in nearly all countries, and the results are published in scattered fragments. To collate, digest and analyze all that these fragments contain, and place the results in a compact form for easy reference, is the sphere of the annuals, which have become a necessity. These not only make it possible for the specialist to keep in touch with the progress made in his particular branch, but they make it possible for one to keep in touch with what is going on in every department of medicine. The year-book before us is one of the few annuals that does this well. The editor has associated with him the best men in the various fields of work, and the result is not only completeness, but, what is of greater moment, reliability. To say that the year-book for this year is as good as previous volumes is all that is necessary. It is now published in two instead of one volume, as formerly, and this is a decided improvement. The first volume is devoted to medicine, and includes pediatrics, pathology, nervous diseases, diseases of the skin, physiology, legal medicine, hygiene, physiologic chemistry, etc. The one on Surgery contains also chapters on obstetrics, ophthalmology, otology, laryngology, etc. As the volumes are sold separately this division will be a saving to those who are only interested in special subjects. A complete index with each volume makes ready reference easy. The illustrations are numerous, the mechanical work excellent, and the book as a whole everything that could be desired.

The Student's Handbook of the Surgery of the Alimentary Canal. By A. Ernest Maylard, M.B., B. S. (Lond.). Pages, 510. Price, $3.00. Philadelphia: P. Blakiston's Son & Co.

This work is an abridged and amended edition of the author's treatise on the same subject published in 1896. Diseases of the mouth, fauces and pharynx are not considered. Hemorrhoids and fistulæ are considered outside the scope of the work, although polypi, and papillomata of the rectum, prolapsus ani and rectocele are included. Of rectocele he says: "The condition is one due to an injury sustained in childbirth which becomes exaggerated as a woman passes the menopause, and as the vagina is shortened in after life." It is certain no one would even recognize the condition by the definition, which describes almost anything except a rectocele.

The attempt to follow too closely the anatomic subdivisions of the canal has led to much repetition. This not only unnecessarily takes up much space which could be made use of to better advantage, but also often detracts from a clear conception of what actually is met with in practice, as for instance when contusions or subcutaneous injuries are separately described as affecting the stomach, the duodenum, the jejunum and ileum and the large intestine.

Under gastrorrhaphy it is stated: "the sutures pass through the mucous and muscular coats." It evidently should read "serous and muscular coats." The intestinal neuroses are disposed of in a few words, about half a page.

No medical treatment is given, but the author says: "When these cases are not influenced by medical treatment, laparotomy should be resorted to. Nothing probably will be found but, in some mysterious way, the exploratory operation has a beneficial effect."

The work contains much useful, general information, but the reader will be disappointed when he searches it for accurate and definite pathology.

Horton's Physician's Perpetual, Daily, Weekly and Monthly Record Sheet. Price $1.00 to $4.00, according to size. Brooklyn, 289 Quincy Street; Alexander F. Horton, M.D.

This unique record sheet is convenient and useful because it can be carried in the pocket, obviates the employment of the old bulky visiting list, takes the place of the day-book, is perpetual, and can be used with any system of book-keeping.

Married.

James Henry Dittemore, M. D., Axtel, Kan., to Miss Margaret Kent, Troy, Kan.

Francis P. Dorsey, M.D., Hartington, Neb., to Miss Louise Pauline Lerch, Smith's Villa, Iowa, February 12.

Robert Leonard Morrison, Clarksburg, W. Va., to Miss Margaret Rathbone Paden, at Parkersburg, W. Va.

Otto Fisher Ball, M.D., to Miss Leonora Montgomerie, daughter of Colonel John J. Clague, U. S. Army, both of St. Louis, February 19.

Deaths and Obituaries.

William H. Egle, M.D., University of Pennsylvania, 1859, librarian and historian, died from pneumonia, at his home in Harrisburg, Pa., February 19. He served two years as surgeon of the Forty-seventh Pennsylvania regiment during the Civil War, and subsequently as a brigade surgeon in the national guard of the state. He was a member of the American Medical Association and other societies. During the past fifteen years Dr. Egle had been relatively passive in medical work, yet his sympathies, time and advice, were always freely given for the general advancement of medical science and the general good of the profession. His last years were almost entirely devoted to literary work and historical research. He had been state librarian in Pennsylvania since 1887 and brought the library to an exalted standard of efficiency. He was a corresponding member of nearly every one of the historical societies in the English-speaking world, and his contributions to the literature pertaining to local and state history and genealogy were many. At a special session of the Harrisburg Academy of Medicine, February 21, which was called to take action upon Dr. Egle's death, highly eulogistic remarks were made by several members of the Academy and resolutions of regret and sympathy passed.

Joseph H. Linsley, M.D., University of Vermont, 1880, died from meningitis, at his home in Burlington, Vt., February 17, aged 42. A year after his graduation he went to New York and was appointed instructor in clinical microscopy in the New York Post-Graduate Medical School, and a year later was made director of the laboratories of histology, pathology and bacteriology, doing in addition the pathological work of St. Luke's and the Presbyterian hospitals. In 1890 he went to Berlin and took a course in bacteriology under Koch. Later, he was made professor of pathology and bacteriology in the University of Vermont. His greatest work was in connection prise at having the treatment unhesitatingly condemned by a man some hundreds of miles away, who is and was as ignorant of what was actually indicated and done as he appears to be of the courtesies due between professional gentlemen.

Snap diagnoses and absent treatment have heretofore been confined to magnetic healers and "Christian Scientists," and this brief experience leads me to hope that such methods will never be adopted by reputable professional men. Very respectfully, J. N. McCormack, M.D.

Another Fraud Solicitor.

Chicago, Feb. 15, 1901.

To the Editor:—I learn that several physicians in Chicago have been victimized, as I was, recently by a scoundrel professing to be the representative of a newspaper subscription agency. I presume the firm which he professes to represent is a reputable one, although I wonder that they do not seem more interested in apprehending this man and prosecuting him, as he is not only collecting money in their name, but forging their signature to checks made out to the agency.

As the magazines for which I subscribed failed to make their appearance some weeks after the visit of this agent, I addressed a letter to Moore's Agency, and received the following reply:

> Your favor of the 14th received, and in reply would say we have no agent by the name of W. R. Neal, and we do not offer any such list of magazines as you mention for $4.00. This man is a fraud, and we have had a great many complaints in regard to him, as he is traveling around through different cities in the West and carrying on this scheme. We do not have any traveling representatives and never allow the agent to present a receipt in our name, as we have thought it liable to lead to some such system of fraud. We have been unable to locate this man as he travels around from place to place, and we do not hear in regard to him until he has left each locality. If you can find any way by which you can secure him we would advise you to take such steps at once. We regret very much that he should have misrepresented himself as our agent and that we are unable to help you out in the matter. Yours truly (signed), W. H. Moore.

As this fellow seems to have victimized a number of physicians in the city, I think it would be well to warn others through the columns of your journal. Very truly yours,

John M. Dodson, M.D.

Feeding in Typhoid Fever.

Boston, Feb. 19, 1901.

To the Editor:—It has been noticed in several cases of fever, especially typhoid, that a total change from an animal food element in diet, and substitution of only vegetable elements was followed by lessened fever, and consequently better sustained strength of the patient.

I am informed that the typhoid bacillus generally develops much more freely on animal culture material than on vegetable, with perhaps occasional exceptions.

Should it not, therefore, seem that the common practice of feeding fever patients with milk and meat juice and such elements as promote the increase of the bacillus and its toxins is simply feeding the fever and thereby weakening instead of sustaining the strength of the patient? A list of foods least promotive of growth of bacilli, also a list of those most promotive might be convenient for reference to the general practitioner. As an inhibitory medicine, harmless in proper doses, sulphite of soda has been thought to aid in retarding the development of bacilli and toxins. Jacob L. Williams, M.D.

Movable Kidney.

Brooklyn, N. Y., Feb. 19. 1901.

To the Editor:—I note with great pleasure, in The Journal of February 9, the paper entitled "Movable Kidney from the Standpoint of the General Practitioner," by Dr. Alexander Marcy, Jr. As these cases are very often of a neurasthenic type, I should like to suggest the employment of lupulin and sumbul combined with either the tincture or extract of nucis vomicæ. There can be no question of the permanent benefit derived from massage and hydrotherapy, properly carried out. Coming now to the local, or mechanical management of nephroptosis, permit me to again call attention to the plaster bandage described by me in the *Medical News* of Sept. 1, 1900, mentioned also by Rose in the *Post-Graduate* for March, 1900. This device is the most satisfactory in every way, of any form of abdominal support, which has come to my notice. It is inexpensive, easily adjusted, not bulky or in any way uncomfortable, and accomplishes its end far better than a ready-made bandage. The special pad for the displaced organ itself, I do not believe avails anything. In contradistinction to the view expressed in the paper under discussion, the above, and not surgical intervention, forms the best mode of treatment for "floating kidney."

The two formulæ I generally employ are the following: In cases in which there is a tendency to constipation: lupulin, 1 gr.; zinc phosphid, 1/16 gr.; sodium bromid, 2½ grs.; gelsemin, 1/20 gr.; arsenious acid, 1/20 gr. These I use, one after meals, and one before retiring. In other cases the following acts admirably: Lupulin, 5 gr. (equivalent to tr. valerian, 1 dram, tr. sumbul, 1 dram), asafetida, 3 gr.; ext. nucis vomicæ, 1/6 gr.; in tablets, taken the same as No. 1.

H. W. Lincoln, M.D.

Accidental Vaccination.

Meadow Creek, W. Va., Feb. 21, 1901.

To the Editor:—In the February number of *Medicine*, a case of vaccin infection was reported. I have seen a similar case. Some time last November a woman came to my office to show me a peculiar looking sore on her neck. I had recently vaccinated a number of persons, and, among them, three children in the family in which this woman was a nurse. On inquiry I found she had been scratched on the neck by one of the children, while taking care of it. She had never been vaccinated. The sore was a characteristic vaccination pustule. I was forced to the conclusion that the child had accidentally conveyed the vaccin from its arm to the neck of the nurse by its finger nails.

G. D. Lind, M.D.

Book Notices.

Diseases of the Intestines. A Text-Book for Practitioners and Students of Medicine. By Max Einhorn, M.D., Pages. 390. Price, $3.00. New York: Wm. Wood & Co.

This treatise is a continuation of the author's work on "Diseases of the Stomach," the two volumes thus covering the principal disorders of the digestive tract. The anatomy and physiology of the intestinal canal are briefly and clearly described. Methods of examination are discussed, but we find no mention of the elevated position so important in proctoscopy nor of the long tubular specula for use in examining the lower bowel. The introduction of the whole hand and arm into the rectum, according to Simon, should only be mentioned to be condemned as it is scarcely possible to conceive of a condition in which such a procedure would be necessary.

A duodenal ulcer is defined as "A defect in the mucous membrane of the duodenum." As a scar is as much a defect as an ulcer the definition is not a good one.

The definition of hemorrhoids is also incorrect, as it states that they are simply "varicose dilatations of the hemorrhoidal veins." A hemorrhoidal mass always consists of something more than varicose veins. There is an hyperplasia of connective tissue in addition to the varicosities. The changes are correctly described under "Morbid Anatomy," but the definition is imperfect.

Under the treatment of appendicitis we find these statements: "The use of cathartics is mentioned here only in order to condemn it." "The remedy *par excellence* in the treatment of appendicitis is opium." These are the views of an internist. In a recent work on appendicitis by a prominent surgeon of an unusually large experience, we find these statements, just reversed: "The most important feature of the treatment of a case of acute appendicitis is the prompt administration of a laxative—an effort should be made to secure at least several stools." "The administration of opium in the treatment of appendicitis can not be too strongly condemned." Such diametrically opposite statements by experienced observers must convince the ordinary man that the course of acute appendicitis is but little influenced by such medicinal treatment. That patient with appendicitis is best off who is soonest rid of his inflamed appendix.

The several varieties of acute intestinal obstruction are clearly described, and the importance of early surgical treatment strongly urged. A very interesting chapter is that on the intestinal neuroses. The volume closes with a chapter on the intestinal parasites. The work, as a whole, is a good one. The author has had a large experience, and writes knowingly of his subjects. The work is also unique in the fact that it is practically the only monograph on the diseases of the intestine in the English language. The practitioner will find in it much useful information.

THE AMERICAN YEAR-BOOK OF MEDICINE AND SURGERY FOR 1901. A Yearly Digest of Scientific Progress and Authoritative Opinion in all branches of Medicine and Surgery, drawn from journals, monographs, and text-books, of the leading American and foreign authors and investigators. Arranged with critical editorial comments, by eminent American specialists. In two volumes—Volume I, including *General Medicine*, Octavo, 681 pages, illustrated; Volume II, *General Surgery*, Octavo, 610 pages, illustrated. Cloth, $3.00 net; Half Morocco, $3.75 net. Philadelphia and London: W. B. Saunders & Co. 1901.

The advance being made in the various departments of medical science is so rapid that it is practically impossible for one to keep up in the various branches of medicine. In fact, it is no easy matter to follow the literature, in one, much less all. There are workers in all fields in nearly all countries, and the results are published in scattered fragments. To collate, digest and analyze all that these fragments contain, and place the results in a compact form for easy reference, is the sphere of the annuals, which have become a necessity. These not only make it possible for the specialist to keep in touch with the progress made in his particular branch, but they make it possible for one to keep in touch with what is going on in every department of medicine. The year-book before us is one of the few annuals that does this well. The editor has associated with him the best men in the various fields of work, and the result is not only completeness, but, what is of greater moment, reliability. To say that the year-book for this year is as good as previous volumes is all that is necessary. It is now published in two instead of one volume, as formerly, and this is a decided improvement. The first volume is devoted to medicine, and includes pediatrics, pathology, nervous diseases, diseases of the skin, physiology, legal medicine, hygiene, physiologic chemistry, etc. The one on Surgery contains also chapters on obstetrics, ophthalmology, otology, laryngology, etc. As the volumes are sold separately this division will be a saving to those who are only interested in special subjects. A complete index with each volume makes ready reference easy. The illustrations are numerous, the mechanical work excellent, and the book as a whole everything that could be desired.

THE STUDENT'S HANDBOOK OF THE SURGERY OF THE ALIMENTARY CANAL. By A. Ernest Maylard, M.B., B. S. (Lond.). Pages, 510. Price, $3.00. Philadelphia: P. Blakiston's Son & Co.

This work is an abridged and amended edition of the author's treatise on the same subject published in 1896. Diseases of the mouth, fauces and pharynx are not considered. Hemorrhoids and fistulæ are considered outside the scope of the work, although polypi, and papillomata of the rectum, prolapsus ani and rectocele are included. Of rectocele he says: "The condition is one due to an injury sustained in childbirth which becomes exaggerated as a woman passes the menopause, and as the vagina is shortened in after life." It is certain no one would even recognize the condition by the definition, which describes almost anything except a rectocele.

The attempt to follow too closely the anatomic subdivisions of the canal has led to much repetition. This not only unnecessarily takes up much space which could be made use of to better advantage, but also often detracts from a clear conception of what actually is met with in practice, as for instance when contusions or subcutaneous injuries are separately described as affecting the stomach, the duodenum, the jejunum and ileum and the large intestine.

Under gastrorrhaphy it is stated: "the sutures pass through the mucous and muscular coats." It evidently should read "serous and muscular coats." The intestinal neuroses are disposed of in a few words, about half a page.

No medical treatment is given, but the author says: "When these cases are not influenced by medical treatment, laparotomy should be resorted to. Nothing probably will be found but, in some mysterious way, the exploratory operation has a beneficial effect."

The work contains much useful, general information, but the reader will be disappointed when he searches it for accurate and definite pathology.

HORTON'S PHYSICIAN'S PERPETUAL, DAILY, WEEKLY AND MONTHLY RECORD SHEET. Price $1.00 to $4.00, according to size. Brooklyn, 289 Quincy Street; Alexander F. Horton, M.D.

This unique record sheet is convenient and useful because it can be carried in the pocket, obviates the employment of the old bulky visiting list, takes the place of the day-book, is perpetual, and can be used with any system of book-keeping.

Married.

JAMES HENRY DITTEMORE, M. D., Axtel, Kan., to Miss Margaret Kent, Troy, Kan.

FRANCIS P. DORSEY, M.D., Hartington, Neb., to Miss Louise Pauline Lerch, Smith's Villa, Iowa, February 12.

ROBERT LEONARD MORRISON, Clarksburg, W. Va., to Miss Margaret Rathbone Paden, at Parkersburg, W. Va.

OTTO FISHER BALL, M.D., to Miss Leonora Montgomerie, daughter of Colonel John J. Clague, U. S. Army, both of St. Louis, February 19.

Deaths and Obituaries.

William H. Egle, M.D., University of Pennsylvania, 1859, librarian and historian, died from pneumonia, at his home in Harrisburg, Pa., February 19. He served two years as surgeon of the Forty-seventh Pennsylvania regiment during the Civil War, and subsequently as a brigade surgeon in the national guard of the state. He was a member of the AMERICAN MEDICAL ASSOCIATION and other societies. During the past fifteen years Dr. Egle had been relatively passive in medical work, yet his sympathies, time and advice, were always freely given for the general advancement of medical science and the general good of the profession. His last years were almost entirely devoted to literary work and historical research. He had been state librarian in Pennsylvania since 1887 and brought the library to an exalted standard of efficiency. He was a corresponding member of nearly every one of the historical societies in the English-speaking world, and his contributions to the literature pertaining to local and state history and genealogy were many. At a special session of the Harrisburg Academy of Medicine, February 21, which was called to take action upon Dr. Egle's death, highly eulogistic remarks were made by several members of the Academy and resolutions of regret and sympathy passed.

Joseph H. Linsley, M.D., University of Vermont, 1880, died from meningitis, at his home in Burlington, Vt., February 17, aged 42. A year after his graduation he went to New York and was appointed instructor in clinical microscopy in the New York Post-Graduate Medical School, and a year later was made director of the laboratories of histology, pathology and bacteriology, doing in addition the pathological work of St. Luke's and the Presbyterian hospitals. In 1890 he went to Berlin and took a course in bacteriology under Koch. Later, he was made professor of pathology and bacteriology in the University of Vermont. His greatest work was in connection with the upbuilding of the Vermont State Laboratory of Hygiene. In 1897 he opened a small laboratory for the examination of cultures for suspected diphtheria cases and typhoid fever, and a year later the state created a bacteriological laboratory, placing Dr. Linsley at its head.

Alexander Neil, M.D., Cincinnati College of Medicine and Surgery, 1863, surgeon throughout the Civil War, a well-known physician of Columbus, and a member of the American Medical Asssociation, died at his home in Columbus after a long illness, February 14, aged 62.

Harris O. Palmer, M.D., Dartmouth Medical College, Hanover, N. H., 1867, who had practiced for nearly thirty years in Hubbardston, Mass., died at his residence in that place from pneumonia, February 17, after an illness of one week, aged 60.

Horace G. Hill, M.D., Jefferson Medical College, Philadelphia, 1882, chief medical director of the Fidelity Mutual Life Insurance Co., a resident of Philadelphia, died at Wernersville, from la grippe, February 14, aged 42.

Almon G. Bruce, M.D., University of Wooster Medical Department, Cleveland, Ohio, 1870, a popular physician, and at one time mayor of Albion, Mich., died at his residence in that place, February 9, from apoplexy.

William E. Curtis, M.D., University of Nashville, Tenn., 1861, a member of the American Medical Association and a leading physician of Carroll County, Tenn., died at his home in McKenzie, February 9, aged 60.

Richard Searing Seaman, M.D., College of Physicians and Surgeons, N. Y., 1851, died at his home in Brooklyn, N. Y., on February 17. He had been in practice at Glen Cove, L. I., for more than thirty years.

Thomas F. Murdoch, M.D., University of Maryland, Baltimore, 1850, a practitioner of Baltimore for nearly half a century, died suddenly at his residence in that city, February 18, aged 81.

William Booz, M.D., College of Physicians and Surgeons, Keokuk, Iowa, 1877, an old resident practitioner and preacher of Hancock County, Ill., died at Carthage, February 20, aged 69 years.

Francis M. Bennett, M.D., Medical College of Virginia, 1881, died recently in Montgomery, W. Va. He was a member of the Fayette County Board of Health and a sanitarian of repute.

William Rice, M.D., University of Pennsylvania, 1860, for thirty years a resident, and twice mayor of Trenton, N. J., died suddenly at his home in that city, February 13, aged 61.

George L. Kirby, M.D., Long Island College Hospital, N. Y., 1860, died February 19, at the state hospital, Raleigh, N. C., of which he had been superintendent since 1894.

Hanly B. Potter, M.D., University of Buffalo, N. Y., 1874, of Lafargeville, N. Y., died February 18, while on a professional visit at Orleans, Four Corners, aged 61.

David W. McConnell, M.D., Starling Medical College, Columbus, Ohio, 1870, died at his home in Marseilles, Ohio, February 20, from pneumonia, after a short illness.

Daniel Handel, M.D., University of Iowa, Iowa City, 1875, was struck by a train at Onawa, Iowa, and died at his home in that place as a result of his injuries, February 19.

Jefferson S. Harbison, M.D., National Medical College, Washington, D. C., 1860, died at his home in Knoxville, Tenn., from Bright's disease, February 16, aged 69.

Lemuel Watson, M.D., Jefferson Medical College, Philadelphia, 1870, of Nebraska City, Neb., died from paralysis after a long illness, February 18, aged 76.

Henry Nichell, M.D., University of Buffalo, N. Y., 1857, a member of the American Medical Association, died at his home in Buffalo, February 14, aged 80.

William P. Manning, M.D., University of Maryland, Baltimore, 1869, died at his residence in Washington, D. C., February 9, aged 56.

G. Byron Lyman, M.D., College of Physicians and Surgeons, Baltimore, Md., 1878, died recently at his home in Yuba City, Cal.

John C. Tedford, M.D., Washington University, St. Louis, Mo., 1859, died at his home in Moberly, Mo., February 13, aged 75.

George T. Watkins, M.D., University of Louisville, Ky., died at his home in Kokomo, Ind., from dropsy, February 18, aged 66.

Thomas C. Neal, M.D., Castleton Medical College, Castleton, Vt., 1848, died at his home in Sugar Creek, N. C., February 9.

I. Newton Jones, M.D., Medical College of Ohio, Cincinnati, 1866, died February 21, from pneumonia, aged 57 years.

Levi Royer, M.D., University of Maryland, Baltimore, died at New Windsor, Carroll County, Md., February 10, aged 61.

Edward A. Glezen, M.D., Ireland, Ind., died at that place, February 12, from la grippe, aged 82.

Miscellany.

Cleansing the Hands. —The hands may be washed in pure carbolic acid without harm if they are washed in alcohol immediately afterward.

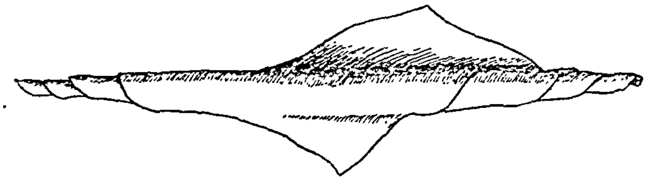
A Memorial to Queen Elizabeth's Physician.—This is to be erected in a niche in the main facade of the new town hall at Colchester, England. This marble statue of Dr. William Gilbert (1540-1603) is to be erected by the medical profession, and the minimum amount required is only £150, of which £130 has been contributed. Dr. Gilbert was a distinguished natural philosopher, as well as physician. His conjecture that terrestial magnetism and magnetism were allied emanations was confirmed more than two centuries afterward by Oersted and Faraday. There is as at present a handsome monument over his remains in the church of the Holy Trinity at Colchester, which was his native town.

Muscular Work and Food Digestibility.—The United States Department of Agriculture has issued its third bulletin upon dietary studies. This work was conducted at the University of Tennessee, from 1897 to 1899, by Dr. Charles E. Wait, professor of chemistry, and a corps of assistants. The drift of this report is that more fat is consumed in the South than is necessary; the leaner meats as beef and mutton should be more the vogue. More nitrogenous vegetable foods, as beans and peas, with less fat and starchy foods constitute a more ideal dietary. In this brochure attention is invited to the great value of the cow-pea as fulfilling most of the indications desired. "Experiments on the Effect of Muscular Work Upon the Digestibility of Food and the Metabolism of Nitrogen" is the title of the article in "Bulletin No. 89."

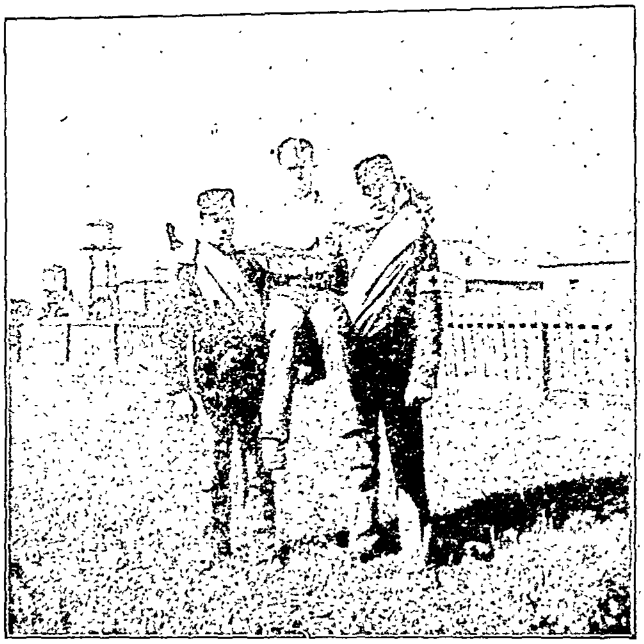
A Remarkable American: Dr. William Pepper.—The *British Med. Jour.* of February 16 publishes the following tribute, by W. T. Gairdner, to Dr. Pepper, who, he says, "was not only a great public benefactor, but one whose friendship I enjoyed in no ordinary measure during a visit to the United States in 1891. In that year I was at Washington, on the joint invitation of Dr. Pepper and Dr. Weir Mitchell, the one the retring president, the other the president-elect of the American Medical Congress. Previously to this, however, I had made a number of visits in New England, and had spent some very happy days with Dr. Pepper at Newport, R.I., where in the autumn season he allowed himself, I suppose, as much of a holiday as he ever had. I think I am justified in saying that there was no one on this side of the Atlantic who was more admitted to his intimacy than I was then, and in our correspondence during the succeeding years, up to within a very few weeks of his premature and sudden death. It was very easy even then to see that he was a man utterly regardless of self, and living only for the sake of his university and his many public functions. It was also not difficult to perceive that his mode of living, the incessant occupation and overstrain were such as to endanger the health and endurance of the bodily machine. I ventured to represent this to him—as I daresay others may have done—but only to find that as long as he did not feel positively ill his only notion of living was to get as much work out of himself as either body or mind would endure, regardless of all but the great interests and schemes with which his name was associated. He was Provost of the University of Pennsylvania at this time, and felt a noble pride in all that he had done and was doing for the higher education in that great center, where out of a large professional income he was devoting what he regarded as the superfluities (for he avowedly disregarded wealth for himself and for his family) with the most lavish and yet calculated munificence to the improvement of the medical, and especially the clinical, department of the University. Dr. Pepper must have been a hard and constant worker from an early period of his career. My first knowledge of him was when he was associated with Dr. Meigs in a work on the 'Diseases of Children,' which passed through several editions, and was—or perhaps still is—a leading work on the subject. His literary activity after this was unceasing, and I pleaded with him for his own sake to abandon some considerable portion of his literary or, alternatively, of his public labors, in order to devote himself more to his private and consulting practice. Some time afterwards he did, in fact, resign the provostship, but as he had at the same time assumed other public duties, I am far from certain that there was any material relaxation of his great and abnormal activity up to the time when he was compelled by sheer disability to leave all his work, and, as it proved, to seek renewed health in a journey which was terminated by his sudden death. He never gave me any hint of cardiac suffering either in conversation or correspondence; on the contrary, he led me to expect some day a pleasant return visit to this country, to which he always looked forward with joyful anticipation, but which was always postponed, more (as I understood) on account of the state of his wife's health than of his own. Few men, in as brief period, have become more endeared to me than Dr. William Pepper; and few men in his own, or any other country, can have lived a nobler life, or one more devoted to the public interest."

A New Blanket Litter.

The Surgeon-General of the Army has issued a circular inviting the attention of his medical officers to a method of carrying disabled men, devised by Acting Assistant-Surgeon C. E. MacDonald, U. S. A., Fort Yates, N. D., which appears to be of value for the transportation of a certain class of wounded in the absence of litters. The method requires the services of two bearers and the use of two blankets or shelter-tent pieces. It has been used for some time as an experiment at all first-aid drills at Fort Yates, and is regarded as preferable to the methods which have heretofore been employed. It has been tested also at the school of instruction for the hospital corps, at the U. S. General Hospital, Washington, D. C., with favorable results.



Each blanket or shelter-tent piece is folded, rolled or twisted into a cylindrical form on one of its diagonals. The two cylinders are placed side by side and their contiguous ends are tied together by reef knots. The bearers then raise the tied blanket rolls and adjust them, the one knot on the right shoulder of the right bearer and the other on the left shoulder of the left bearer, one blanket cylinder curving from shoulder to shoulder in front and the other behind. To prepare the blanket litter or seat for the patient the bearers kneel, the right bearer on his left knee and the left bearer on his right knee. They then pull the middle part of the posterior cylinder to the front underneath the corresponding part of the anterior cylinder which is at the same time drawn to the rear so as to form a sitting space of six or eight inches enclosed between the rolls. The patient is placed on this space and is supported behind by the contiguous arms of the bearers. Figure 2 shows them ready to march off with their burden. Acting Assistant-Surgeon MacDonald has used these blanket cylinders successfully as an extemporized litter for patients with the lower extremities immobilized by a rifle splint.



Societies.

COMING MEETINGS.

Medical Society of the Missouri Valley, Omaha, Neb., March 21, 1901.

German Congress of Otology.—The German Otological Society holds its annual meeting this year at Breslau, May 24 and 25. The arrangements are in charge of Professor Kuemmel, Thiergartenstrasse 53, Berlin.

John B. Deaver Surgical Society.—The John B. Deaver Surgical Society of the University of Pennsylvania held its fifth annual reunion in Philadelphia, February 11. Dr. Deaver presided and the twenty student members of the Society entertained about seventy-five guests.

El Paso County (Colo.) Medical Society.—This Society held its annual meeting at Colorado Springs, February 13, and elected Dr. Robert K. Hutchings, president; Dr. John O. Reddie, vice-president, and Dr. Frank L. Dennis, secretary and treasurer, all of Colorado Springs.

Medical Society of the City of Carrollton, Ga.—The physicians of Carrollton met on February 15 and organized a local society with the following officers: Dr. Stevens T. Harris, president; Dr. M. M. Hallum, vice-president; Dr. J. F. Cole, secretary, and Dr. Delvous Houseworth, assistant secretary.

Pomona Valley (Cal.) Medical Society.—At the meeting of this Society, in Pomona, January 31, the following officers were elected: Dr. Conley Heaton, Pomona, president; Drs. William A. Lillie, Ontario, and T. Hardy Smith, Pomona, vice-presidents, and Dr. Edward Henderson, Pomona, secretary and treasurer.

Western Ophthalmologic and Oto-Laryngologic Association.—Dr. W. L. Ballenger, Chicago, secretary of this Association, announces that the next annual meeting will be held in Cincinnati, April 11 and 12. Dr. Christian R. Holmes is chairman of the local committee of arrangements.

North Montana Medical Society.—At the regular monthly meeting of this Society, at Great Falls, Dr. Ernest Crutcher offered resolutions recommending the prompt enactment of a pure food law and of a statute governing the inspection of milk and dairies in towns of 1500 or more inhabitants. The resolutions were adopted.

Belmont County (Ohio) Medical Society.—The tenth annual dinner of this Society was held in Bellaire, February 22. Dr. J. Park West, welcomed the guests; Dr. James S. McClellan acted as toastmaster, and Drs. A. H. Hewitson, St. Clairsville, and Arlington W. Diven, Martins Ferry, responded for the nineteenth and the twentieth century doctor respectively.

Orange County (N. Y.) Medical Association.—A meeting of the members of the Fifth District Branch of The New York State Medical Association was held in Middletown February 12, and the Orange County Medical Association was organized. Dr. Milton C. Conner, Middletown, was elected president; Dr. Frank W. Dennis, Unionville, vice-president, and Dr. Charles I. Redfield, of Middletown, secretary and treasurer.

Chautauqua County (N. Y.) Medical Association.—A meeting of the members of the Fourth District Branch of the New York State Medical Association was held at Jamestown, February 13, and the Chautauqua County Association was organized. The following officers were elected: Dr. Thomas D. Strong, Westfield, president; Drs. William M. Bemus, Jamestown, and A. C. Shaw, Cassadaga, vice-presidents, and Dr. Henry A. Eastman, Jamestown, secretary and treasurer.

Johns Hopkins Historical Club.—At the meeting of the Johns Hopkins Hospital Historical Club, February 11, Dr. Tinker read a paper entitled "The First Nephrectomy and First Cholecystotomy." Both were performed by Americans from the West, the first by Dr. E. B. Wollcott, of Milwaukee, June 4, 1861. It was reported in the *Philadelphia Medical and Surgical Reporter*, Vol. 7, 1861-2. The second operation was performed June 15, 1867, by Dr. J. S. Bobbs, of Indianapolis, and was reported in the Indiana Medical Society Transactions, 1868. The patient was still living in 1899.

International Institute of Psychology.—The Institute has its headquarters in Paris and formally commenced its labors January 30. The committee of organization includes F. W. H. Myers, for England; Morton Prince, for America; Lombroso, for Italy; Mendeleeff and others, for Russia; Flournoy, for Switzerland, and Schrenk-Noetzing, for Germany. The lectures will be held at 5 p.m., and some of the most prominent psychologists and physiologists of Europe are on the list of speakers. Among the subjects announced are "Application of Psychology to Medicine"; "Relations Between Experimental and Introspective Psychology"; "Practical Applications of Hypnotism and Moralizing Suggestion", and "Conductibility of Psychic Force."

Will County (Ill.) Medical Society.—This Society held its regular meeting at Joliet, February 15.—The special business of the session was the discussion of certain bills now before the legislature, which especially interest the medical profession, and regarding which the Illinois State Medical Society, through its judiciary council had asked an expression of opinion. First among these was the isolation of tubercular convicts. The idea of this bill is to do away with the custom which has prevailed in the penal institutions of the state, where tubercular convicts mingle in the hospital and workrooms with the other convicts both sick and well. It is proposed to provide a room or ward in the hospital, and where this is not possible, to provide a separate building where tubercular convicts can be isolated, with the hope of preventing the spread of tuberculosis and diminishing the death-rate of the convicts from this disease. It was the opinion of the society that this bill should pass. The establishment of a state sanitarium for the tubercular was next considered. From information at hand the society was unable to determine whether it was the intention to provide a state institution for the care of the indigent tubercular to be cared for at the expense of the state, or whether the institution was to receive all cases of tuberculosis. In either event, the society considered that the establishment of such an institution would be a step in the right direction. The society unanimously approved the bill providing for the establishment of a colony of epileptics similar to the Craig Colony of New York State, and that making boards of county commissioners in counties not organized on the township basis boards of health, and inasmuch as every county should have a board of health empowered to discharge the duties pertaining to such. Pending definite information regarding the proposed bill amending the medical practice act, so as to give the State Board of Health power to revoke diplomas issued prior to 1899 "for causes," the society instructed the secretary to ask for more details regarding the matter. The Society voted unanimously in favor of the bill amending the medical practice act so as to eliminate the "Christian Scientists."

ASSOCIATED HEALTH AUTHORITIES AND SANITARIANS OF PENNSYLVANIA.

Eighth Annual Meeting, Held at Harrisburg, February 6.

About seventy-five delegates were present, representing nearly every part of the state.

Report of Legislative Committee.

The committee presented several bills which it desired the legislature to enact, for the increase of the annual appropriation to the State Board of Health, to enable it to carry into effect the registration of the vital statistics of the state, to prevent the pollution of the streams which provide water-supply for domestic use, to provide for a sanitary survey of the waters of the state, to make mandatory the law already enacted giving power to school boards to act as health boards, to make the wardens who now act to prevent destruction of the forests act as health wardens and to give the secretary of the state board an increase of salary commensurate with the work he is now doing. It was seemed advisable to urge for a sanitary survey of the waters as an entering wedge toward providing for greater powers to enable the domestic water-supply to be placed under the guardianship of the state board, and thus prevent the present fearful pollution which obtains almost everywhere in the state.

The discussion which followed the reading of these bills showed an almost unanimous belief in the great need of such action, while there was expressed a fear that the passage of these was almost impossible, as the tanneries, saw-mills, etc., are united in opposing them as interfering with their rights to use the waters everywhere as common sewers. It was suggested that the health inspectors in each county could be better used than appointing new officers called health wardens.

Diphtheria Antitoxin and Quarantine.

Dr. E. G. Matson, bacteriologist of the Bureau of Health of Pittsburg, read a paper on the immunizing value of diphtheria antitoxin and the responsibility of municipal boards of health for the prevention of diphtheria. He showed how the disease had increased everywhere, and how by careful quarantine it can be controlled, demanding the report of all cases by physicians and others, and alluded to the success obtained in regard to smallpox and vaccination, but the quarantine and thorough reporting demanded. Diphtheria is more difficult to recognize, requiring a bacteriologic examination to prove its presence and so often regarded as an ordinary sore throat, till too late to prevent its spread. Quarantine, always difficult, is doubly so and in many cases too late to aid in its control.

A thorough discussion followed this paper and showed quite a difference of opinion as to the value of diphtheria antitoxin, as well as the benefit of quarantine. The long continuance of the bacilli in the throat after all severe symptoms have passed, causes great trouble as to the continuance of the quarantine, and demands the utmost vigilance and repeated bacteriologic examinations. Formaldehyde was extolled as of great value, and several health officers said they had positively prevented any recurrence of the disease by its use.

During the discussion, a prominent manufacturer of diphtheria antitoxin startled the assemblage by announcing his want of confidence in antitoxin in the disease. He had lost 90 per cent. of cases in spite of its free employment. In rebuttal one physician stated that he had a success of 100 per cent. where he used this agent. It appeared that many physicians reported all sore throats as diphtheria, while many others failed to report because they regarded the cases as only those of sore throat. For a few minutes the discussion was quite animated, with the result of making many doubtful what they ought to believe.

[It must be remembered that the Association is composed of delegates from the local boards of health, and in many instances these are not medical men, nor in any way posted in the science of medicine. They are appointed by the councils of the boroughs or township, often for their activity as political workers, in fact one board was removed for too great activity as sanitarians, because it offended a prominent local politician by compelling him by law to remove a nuisance after he had refused to obey an order for its removal.—Ed.]

Porto Rico Conditions.

Surgeon G. G. Groff, late brigade surgeon, U. S. A., at Porto Rico, and president of the Superior Board of Health of that island, corrected many false views as to the place, described at length the diseases which prevail, the absence of smallpox—formerly very prevalent, now stamped out by thorough vaccination, about 800,0000 people having been vaccinated —the almost equal removal of yellow fever by the sanitation carried forward in every part. He showed how the poor live in almost complete want of proper and sufficient food, or housing, the want of energy on the part of the people under the reign of the Spaniards, and the present rapid improvement under the work of the military authorities of the United States. There is the chief board, or Superior Board of Health, to which the local boards in each of the more than eight hundred municipalities report. He spoke of the almost total absence of typhoid fever, scarlet fever, etc., and the prevalence of anemia due to the condition of the people as a whole. He showed the effects of the late tornado, which devastated the whole island, and how many still live among the ruins of their houses waiting till they can be given aid to rebuild. The lecture was illustrated by views thrown on a screen.

Mine Sanitation.

In a paper on this subject a mine foreman showed the want of care in the removal of smoke and powder smoke from the passages, etc., the need of men working with their feet constantly wet and water dripping on them from above, and stated that the principal disease was miners' asthma, incurable and very distressing, remaining after many years removal of the patient from mine work.

Mr. John S. Fulton, president of the State Board of Health, said he had been engaged for many years among miners, and never found them specially unhealthy; they live to old age, many very comfortable, in short, he regarded the paper as all wrong, and objected to its being published with the proceedings in the journal, *Public Health*.

Pollution of Streams.

The Legislative Committee presented certain supplementary reports on changes in the acts presented above, and this brought up the pollution of waters by the refuse of tanneries. Hair from hides has been found in Clarion, sixty miles below the tanneries, in the pipes supplying water to that city. As many hides come from abroad, and are notoriously infected with disease, the danger to the users of this water is great. A number of members demanded the passage of acts to protect the domestic waters of the state. The contamination of ice was introduced, and the question asked as to the effect of freezing in expelling germs of disease from water. On this head many held peculiar views, in that they insisted that all germs were thus destroyed or rendered harmless. The bacteriologists present, however, insisted that germs are constantly found in ice, hence ice made from polluted water is dangerous.

Officers for 1901.

The officers elected for the ensuing year are: Crosby Gray, Pittsburg, first vice-president; Dr. H. H. Whitcomb, Norristown, second vice-president; Dr. E. S. Wagner, Mechanicsburg, third vice-president; Jesse C. Green, D.D.S., West Chester, treasurer; Dr. Wm. B. Atkinson, Philadelphia, secretary.

CHICAGO PATHOLOGICAL SOCIETY.

Meeting held February 11.

Dr. L. Hektoen, president.

Osseous Stylohyoid Arch.

Dr. Thomas R. Crowder described three cases of osseous stylohyoid arch. The stylohyoid arch is a constant structure in the higher vertebrates. In many, as the horse, cow and sheep, it is completely bony; in man it is largely ligamentous. Developmental defects with more or less ossification are not infrequently found, but complete bony arch is rare. The three cases presented were not recognized before death. The anomaly is to be looked upon as a developmental defect and not as an ossification of the stylohyoid ligament once developed in the normal way. It has no clinical significance beyond the possibility of fracture——an unlikely accident.

Blastomycetic Dermatitis.

Dr. F. G. Harris reported a case of blastomycetic dermatitis in a woman 78 years old. The growth was located on the gluteal region and commenced four years ago, as a pimple which became a roughened area of intense itching and later became apparently denuded. The growth was 11 cm. long by about 6 cm. wide, having an elevated border bearing flattened papillomatous outgrowths which overhung the floor, the latter being covered with villus-like epithelial projections interspersed with areas of ulceration. The entire growth was movable on the underlying tissues; there were no secondary growths on any part of the body, nor was there any evidence of syphilitic infection. Microscopic examination showed a hyperplasia of the rete mucosum which grew down into the corium in branching, coral-like projections. In these epithelial down-growths were miliary abscesses containing the blastomycetic organisms which were present in groups of three or more. Many of them were in the process of budding. There were no cultures made from this case, on account of the diagnosis not having been made clinically.

Dr. D. Lieberthal referred to a case recently observed, in which a provisional diagnosis of syphilis was made, where the blastomyces were found in sections. He still held to his original diagnosis.

Dr. H. T. Rickets said that the histology of blastomycetic dermatitis is a specific one and entirely different from that of tuberculosis and syphilis.

Dr. H. G. Anthony spoke of the points of difference between blastomycetic dermatitis and the syphilitic and tubercular lesions resembling it.

Dr. L. Loeb called attention to the fact that blastomycetic dermatitis had not been produced experimentally.

Dr. W. E. Coates compared blastomycetic dermatitis to certain diseases in plants. He considers the organisms observed in the skin lesions as spores of fungi.

Dr. F. G. Harris stated that his case was treated with iodids for three weeks, without any improvement.

Secondary Carcinoma of Lungs

Dr. E. R. Le Count demonstrated a diffuse secondary carcinoma confined to the lymph channels of both lungs of a man who died from carcinoma of the stomach, while in the service of Dr. Kramps, at the St. Elizabeth Hospital; the condition was correctly diagnosed during life. At the necropsy, the usual large metastatic tumor nodules were found in the liver, together with an extensive involvement of the peripancreatic, retroperitoneal, peribronchial and peritracheal lymph glands; the adrenals were the seat of a very extensive carcinomatous growth; there were small tumors in the outer parts of both kidneys. The primary tumor from which all these metastatic growths arose was located near the pyloras and showed no features other than are often observed in gastric carcinomata. The lungs were alike in appearance: both possessed very extensive subpleural, linear branching and tortuous carcinomatous growths in the lymph channels, as well as tumor masses in the lymph channels of the deeper parts of the lungs. There were no nodular growths in the lungs, as are observed in consequence of the embolism of tumor cells. The lungs were fresh, no microscopic examination having been made, but the gross appearance supported, in all its details, the opinion that a retrograde lymphatic metastasis had occurred in these channels from the lymph glands at the roots of the lungs.

Toxic Effects of Formaldehyde.

Dr. Martin H. Fischer reported the results obtained from a study of the toxic effects of formaldehyde and its aqueous solution, formalin. The inhalation of formaldehyde is accompanied by marked inflammatory changes throughout the respiratory system. Dyspnea, depression of temperature, tachycardia, weak pulse, and vomiting follow the introduction of formalin into the stomach. Sudden death may result. The severity of the symptoms and the degree of histologic disturbance bear no relation to the strength or quantity of the injected formalin. The gastritis is characterized by intense congestion, necrosis and leucocytic infiltration. Intraperitoneal injections produce a fibrino-hemorrhagic peritonitis of varying intensity, according to the strength of the solution. The peritonitis following chronic formalin poisoning produced by injecting small amounts of dilute formalin intraperitoneally, is accompanied by great connective tissue proliferation, and a striking eosinophilia. Subcutaneous formalin injections produce marked exudation and leucocytic infiltration. The introduction of formalin into the conjunctival sac is followed by an iritis, which, when a single drop of the concentrated chemical is used, may be sufficient to permanently injure the eye.

In whatever way formalin is introduced into the body, certain systemic changes result. Degenerative changes and focal necroses are found in the liver and kidneys. The leucocytic infiltration following the introduction of formalin is characterized by the eosinophiles appearing first; these are followed by the other polynuclears; last of all appear the mononuclears. It is believed that differences in osmotic pressure are to be held accountable for the exudation. The death of the cell is accounted for in two ways: 1, by disturbances in osmotic pressure and, 2, by a deleterious chemical action—probably the reducing power of formaldehyde.

PHILADELPHIA ACADEMY OF SURGERY.

Meeting held February 5.

President Dr. DeForrest Willard in the chair.

Incision for Mammary Carcinoma.

Dr. **William L. Rodman** read a paper entitled "The Best Incision in Operations for Mammary Cancer." In removing carcinoma the incision, whichever is used, should be of such length as to carry it well into the axilla, so that all the lymphatic glands are removed. One should guard against making transverse incisions across the lymphatic channels, since that might be a means of further infection. The fascia about the pectoral muscles should be entirely removed, if not all the pectoral muscles themselves. In the Kocher operation retractors become necessary to expose the axillary vessels. The Halsted operation is still more radical. The essential features are to make an incision so as to include all the infected skin; it should be of sufficient length to expose all the axillary vessels and glands; it should be completed in a reasonable length of time. In three cases in which the Warren operation was done it proved beneficial. Primary union occurred in all of them. This operation can be done more quickly than the Halsted operation and a better use of the arm results.

Dr. **Joseph Hearn** thought that the results had been good. Personally he had been in the habit of beginning the incision below the clavicle, exposing the blood-vessels and ligating them, thus preventing hemorrhage.

Dr. **W. J. Taylor** asked whether a straight incision gave sufficient space to view the axillary vessels.

Dr. **G. G. Davis** stated that his experience had been that it was hard to close the incision by any method employed. In the Halsted operation the cicatrization was hard to overcome. As to controlling hemorrhage, he believed it very difficult and thought a large number of forceps necessary.

Dr. **John B. Roberts** thought that the early period of time with which the speaker had been able to dismiss the cases from the hospital showed that the results had been good. He had been in the habit of beginning the incision above the clavicle so as to expose the lymphatics in the supraclavicular space, afterward making an incision down through the infra-clavicular space. In his opinion both pectoral muscles should be removed.

Dr. **W. L. Rodman**, in closing, stated that he had not tried the vertical incision in the Warren operation. He had not been in the habit of opening the supraclavicular space in this operation. He believed the records would go to show that carcinoma is more frequent in the colored than in the white race.

Abscess of Lung.

Dr. **Joseph Hearn** exhibited "A Case of Abscess of the Lung Following Gangrene in which Pneumotomy had been done." The patient was a man about 24 years of age, who had suffered from an abscess in the lung, and this had been opened; after an injection of a solution of methylene blue, this would be immediately expectorated, showing that there was a direct communication between the cavity and the trachea. A drainage-tube was inserted in the wound after the operation, and left *in situ* for a long period. The communication between the abscess cavity and the trachea still exists, as shown by the methylene blue test. The patient has greatly improved and is now on his way home. The question at present is how to best close the large opening which still remains in the right hypochondrium where the operation was done.

Dr. **W. Barton Hopkins** was under the impression that strapping the side might have a tendency to close the wound.

Thoracic Aneurysm.

Dr. **De Forrest Willard** reported "A Case of Traumatic Thoracic Aneurysm Treated by the Introduction of Wire and Electricity." The patient was a man aged 23 years, who, in August, 1900, sustained an injury from the fall of a heavy wooden box which struck him on the chest. Subsequently much distress was shown, with some hemoptysis. Six months later there was pulsation in the right chest. There was no tracheal tugging, nor suprasternal pulsation. From the clavicle to the axilla on the right side, dulness could be elicited, and on auscultation a systolic murmur could be detected, which was not transmitted to the carotids. The heart was pushed to the left and the impulse was rather forcible. The man finally began to lose flesh and strength, complained of pain and an operation was advised. The speaker had then by means of a canula introduced about twenty feet of silver wire—No. 25—into the aneurysm. On introducing the canula the blood rushed out rythmically with the heart's beat, which at first gave rise to some apprehension, but as soon as the galvanic current—40 milliamperes, increased 5 milliamperes every few minutes until 80 milliamperes had been reached continuing for one hour—had been turned on the hemorrhage at once ceased and did not recur. The patient was not under the influence of an anesthetic. At the end of two weeks the aneurysmal sac has diminished one-third in size and the patient has greatly improved.

Dr. **D. D. Stewart** had first employed this operation in 1890. As a preliminary step he always introduces a canulated needle to determine the thinnest portion of the sac wall, after which he then introduces gold or silver wire of 28 to 29 gauge. He generally inserts about fifteen feet. At present he is in favor of introducing two or three feet of wire in several different regions of the sac. What is desired is to coagulate the albumin, and to dissociate the watery elements of the blood; therefore electrolysis must necessarily occur to be of benefit. In applying the galvanic current he always begins at zero, gradually increasing every few minutes until 65 to 80 or even 100 milliamperes have been reached. He would not advocate the introduction of iron wire in these cases, since too much detritus might occur. An important feature is to make the patient understand that there is little or no danger in the operation per se. One of his cases lived for three years after the operation, then dying of some other disease.

CHICAGO ACADEMY OF MEDICINE.

Meeting held January 10.

Dr. Sydney Kuh in the chair.

Relations of Carcinoma of the Stomach to Chronic Round Ulcer of this Organ.

Dr. **Gustav Fütterer** presented a preliminary paper on this topic. His conclusions are:

1. Mechanical irritation or friction is a most important factor in the production of carcinoma.

2. Mechanical irritation or friction must be of a certain quality in order to produce carcinoma. Instances of this casuistic of carcinoma are related and the presence and location of proliferations of the mucous membrane of the stomach after the same mechanical conditions could be created as they

exist in large ulcer in man prove the importance of a certain quality of mechanical irritation.

3. Mechanical influences displace epithelial cells into the intermediary apparatus of nutrition, thus causing a practically unlimited proliferation of the displaced cells, apparent, not real inherent malignancy, metastasis and, through the overloading of the circulation with the physiologic products of the transplanted cells, different forms of cachexia.

4. It seems that—as a rule—the displacement occurs gradually while the possibility of a successful sudden displacement of normal epithelial cells can not be denied, notwithstanding the fact that all experimental research in this direction by others and also by myself have, so far, been unsuccessful.

5. Large ulcer of the stomach on section has the characteristic form of a fish-hook.

6. Carcinoma of the stomach when found with an ulcer, healed or not healed, must be considered secondary to the ulcer.

7. Carcinoma of the stomach when originating from a scar, grows from the point of the "fish-hook."

8. I have been able to create atypical growth of glands in the mucous membrane on the margin of an artificial ulcer of the stomach in a rabbit, that had all the characteristics of gastric ulcer in man and which showed the histologic changes of an adenocarcinoma, but there were no metastases, no cachexia and, therefore, real malignancy could not be proven.

9. From a number of reasons which present themselves against the theory of a parasitic cause of carcinoma, I would call attention to only one that appeals to me most forcibly: it is the non-infection of the cells and organs invaded by metastasis. If parasites were the cause of carcinoma they would infect the cells of the organs, and whose cells would participate in the growth, but they never do.

DR. LEO LOEB agreed with the conclusions of the essayist, especially as to the place where carcinoma originates. In a large number of observations made on animals, for instance, he found that the principal seat of carcinoma was in the eye. The theory of Dr. Fütterer as to the origin of carcinoma in the stomach could be just as well applied to the origin of carcinoma in the eyes of cattle.

DR. SYDNEY KUH stated that many years ago physicians were taught that one of the most, if not the most important, causes of carcinoma was a continued irritation. He had seen one case demonstrated which seemed to show unmistakably the effect of such constant irritation in producing carcinoma. It was a case of carcinoma of the perineum, and the constant irritation necessary as an etiologic factor was furnished by the patient being a circus-rider.

Therapy of Ointments.

PROF. C. S. N. HALLBERG presented a paper on this subject. He stated that the vehicles for ointments have, as a rule, been selected without any discrimination as to the therapeutic character of the vehicle per se. Many observers have shown the necessity for distinction in the choice of various fats, oils and waxes, both of animal, vegetable and mineral derivation, which are employed as the "basis," or more correctly the vehicle for ointments and allied preparations. From the researches of J. V. Shoemaker and many other observers, the ratio of absorbability of the various fats, as indicated by the general therapeutic purpose of the different ointments, may be classified as follows:

1. *Epidermatic:* Protective, emollient, antiseptic, counterirritant, germicide and parasiticide ointments require a non-absorbable vehicle, viz., petrolatum.

2. *Endermatic:* Cooling, anodyne, alterative, local-irritant, resolvent, sedative and stimulant ointments require absorbable fats, such as lard, suet, fixed oils and waxes of animal and vegetable origin. These become quickly rancid unless carefully prepared and preserved, and some of them are being discarded for mixtures less liable to decomposition and change, such as cacao-oil and wool-fat (lanolin). The oleates are also useful.

3. *Diadermatic:* Constitutional or systemic, directly absorbable. For ointments applied by inunction of mercury, iodin, iodids, etc., the vehicle is hydrated wool-fat (Adeps lanæ hydrosus, U. S. P.) or lanolin.

Between these generalizations there may be many modifications, such as wool-fat and petrolatum mixtures as substitutes for lard, owing to their immunity from rancidity.

In dermatology, ointments of the two first classes would alone be indicated, the purified petrolatums of different melting points affording a range of consistencies for the various epidermatic uses of ointments. Pure and carefully rendered leaf-lard and mutton suet, benzoinated according to the official process, furnish excellent vehicles for the endermatic effects, but they are prone to rancidity and reaction with mercurials and other agents required for incorporation. According to Shoemaker, the oleates penetrate into but not through the skin, and they are therefore well adapted for endermatic use. This includes the "soluble" oleates or soaps, as well as the oleates of the metals, mercury, lead, zinc, etc., and the alkaloids, or the so-called "insoluble" soaps.

In ophthalmology the principal ointments employed are those of the mercury compounds. The yellow mercuric oxid, the most largely used, should be made with petrolatum. In order to obtain the most intimate division of the oxid it is preferably prepared by levigating the freshly precipitated yellow oxid with the soft petrolatum vehicle. Benzoated and hydrated wool-fats are also used for zinc oxid and for diluting the mercuric nitrate ointment.

For systemic effect, hydrated wool-fat is the most effective vehicle, the rapidity of its absorption having been demonstrated by the presence in the urine in a short time of mercury, iodin, quinin and similar agents, after inunction with ointments prepared with this vehicle. The oleates and soaps, not passing through the skin, should not be employed for diadermatic or systemic effect.

DR. JACOB FRANK read a paper on Ureteral Implantation, which will appear in THE JOURNAL.

OMAHA MEDICAL SOCIETY.

Meeting held in Omaha, Neb., February 12.

Puerperal Sepsis.

DR. C. C. ALLISON, in a paper on this topic, pointed out that puerperal fever follows an infection of some part of the parturient canal. The determining conditions are intrinsic and extrinsic. The most important intrinsic factors are: 1. The rich supply of lymphatics surrounding the vagina and uterus: their anatomic relations as they leave the pelvic floor or uterus to reach the lumbar glands. 2. The relations of the reflected peritoneum to the pelvic organs. 3. The presence of the thick bed of subperitoneal areolar tissue which increases the mobility of this serous membrane and is a dead space encouraging free exudation. 4. As a conservative feature, the pelvic peritoneum is less susceptible to mycotic influences because of the comparative absence of stomata vera upon its surface. The most important extrinsic factors are: 1. The extensive wound, the parturient canal, which affords numerous atria from which an infective lymphangitis may develop. 2. The presence of decomposing material upon this surface. 3. Microbic development of different degrees of infectivity.

We have a vulnerable condition of the patient, and the presence of a surgical wound bathed in effete material leading often to a blood clot deeply situated. We are unable to apply a modern surgical dressing. Clinically, the types of sepsis are sapremic, septicemic, or pyemic. Sapremic symptoms are due to absorption of blood clots, lochia, residual membranes or of toxins, due to surface suppuration or to inflammation of the vagina or of the endometrium. In the latter form, we meet with infective thrombosis of the vessels followed by extensive gangrene involving the entire uterus. The sapremic symptoms are early pyrexia, full pulse, free, offensive lochia, a small amount of pain followed by free perspiration and, in favorable cases, a crisis. In unfavorable cases, superficial suppuration is present, the general symptoms are more severe, the temperature and pulse are farther from the normal, local tenderness is greater and the secretions are more impaired. This is the beginning of a septic adenolymphangitis. The vessels are fed by ulcerated areas of some portion of the canal. This lymphangitis is a common attendant on peritonitis, and there is fixation of the pelvic organs due to extensive exudate. Examination shows the uterus fixed, the abdominal muscles rigid, a boggy mass in the vaginal vault, a lessened discharge, a remittent fever and well defined pelvic pain. Treatment demands the use of the douche to remove decomposed matter from the vagina or uterus and the sterilization of any local, ulcerated surface. Carbolic acid followed by alcohol is the best caustic. Retained membrane or placenta should be removed by gentle curettage. In most cases, the pelvic and lumbar glands are engorged but not actually broken down, and yet vaginal drainage behind the uterus is a most logical therapeutic aid. Uterine curettage alone is not sufficient, nor is drainage of Douglas's cul-de-sac alone; the best results are obtained from the use of the two combined. When there is active sepsis, slight jaundice, rapid pulse, variable temperature, an enlarged abdomen, a soft uterus with a greenish cervix, we may know there is a septic thrombosis and gangrene of the uterus, a condition very rare, due to the streptococcus and fatal unless the uterus is removed by vaginal section.

Puerperal septicemia shows severe shock, severe rigors and a feeble pulse. The micro-organisms pass directly into the blood, overwhelm the patient and yet cause little distress. These cases are usually fatal and too much, rather than too little, local treatment is apt to be employed.

JOHNS HOPKINS HOSPITAL MEDICAL SOCIETY.

Meeting in Baltimore, Md., February 4.

Dr. Howard A. Kelly, president, in the chair.

Obstructive Jaundice with Xanthoma Multiplex.

Dr. William Osler exhibited a woman aged 39, who had typhoid fever with cholecystitis in 1897. She has had three attacks of biliary colic since that and a jaundice which still persists, and has had several chills. A diagnosis of gall-stone in the common duct has been made and she is to be operated on. An unusual feature in the case is a xanthoma multiplex. Numerous small patches, like pieces of chamois skin set in the skin are scattered over the hands, axilla, neck, toes, elbows, back, joints, etc., chiefly folds of skin and exposed parts. In places they form distinct tuberous elevations, in others flat patches—*x. planum*. There is one small patch on the mucous membrane of the mouth. Occasionally they completely disappear. The condition is never serious and it is hoped it will disappear after operation.

Case of Arsenical Neuritis.

Dr. Florence Sabin reported the case of a young woman who entered the hospital two months ago, after having taken ʒi of rough on rats. She remained well for two hours, then began to vomit. The stomach was washed out repeatedly and arsenical antidotes with castor-oil given. There was no further symptoms and she left the hospital five days later. On going upstairs, when she reached home, she felt a numbness in her feet. For six days she had fever with painful micturition. The numbness increased and double foot and wrist drop developed. She was unable to feed herself. There was degenerative reaction, some thickening of the skin on the soles and scaling of the palms. The slightest touch of the feet gives pain and there is also very marked tenderness of the calves and abdominal muscles, but no edema.

Dr. Osler reported a case of arsenical neuritis following the medicinal administration of the drug to the amount of ℥i and ʒii.

Dr. Hurd reported one from the ingestion of an uncertain amount of the drug taken with suicidal intent.

Case of Pemphigus Vegetans.

Dr. L. P. Hamburger exhibited a white man, a farmer, aged 52, on whom this affection began one year ago with blisters in the mouth, followed by ulcers. The pemphigus appeared in June, 1900, beginning in the groin as little pimples. He was treated with mercury and iodid without result. He has lost 75 or 80 pounds, has new lesions in the mouth, nostril and on his tongue, resembling mucous patches, also a discharge from the right ear. A syphilitic history can not be made out, but he has had malaria and there has been pulmonary tuberculosis on his mother's side. Fungating masses are seen in the axillæ and groins, and large erosions over the back. There is much salivation.

Ovarian Organotherapy.

Dr. Wilmer Krusen, of Philadelphia, read a paper on the use of the ovarian extract, 5 grs. a day, in 100 cases of amenorrhea and other pelvic disorders. While he met with some striking results, on the whole, the treatment proved a failure, and no definite reliance is to be placed on the agent. No benefit was seen in amenorrhea and dysmenorrhea, but better results in the artificial menopause. It was, however, harmless. The use of the agent is based on a false theory since the ovary is not a secreting organ.

Frequency of Typhoid Bacilli in the Blood.

Dr. R. I. Cole reported results of investigations on this point. He removes 8 to 10 c.c. of blood from the arm, using forceps and not touching. Cultures were made in 15 cases, eleven of which were positive, and in six of the eleven the bacilli were isolated before the Widal reaction was positive. The bacilli were found much more frequently, and for a much longer time than is usually supposed. He obtained them in mild more than in severe cases. The method is valuable when the Widal is delayed. The earliest day on which he found the bacilli was the sixth.

Dr. Wm. Osler said that there are cases in which the diagnosis could not be possibly made without the blood examination.

PHILADELPHIA PEDIATRIC SOCIETY.

Meeting held February 12.

Dr. T. S. Westcott in the chair.

Jacksonian Epilepsy.

Dr. J. D. Target reported two cases of Jacksonian epilepsy. In one, the patient was 2 years and 10 months old, and had been well until three months before being seen, when it had a convulsion mostly confined to the left leg. During the past few months there has been paralysis of the left leg, which has grown much worse.

The second patient is 8 years of age, and has suffered from whooping-cough and measles. When two years old she had a "nervous" spell. Similar attacks have recurred at intervals and are growing worse. In September of last year the child was late at school one morning, and, frightened because of this, she fell in the hallway, where she was subsequently found. The left leg was paralyzed, and in this part convulsive movements set in. This attack was attended by unconsciousness. Some time later convulsive movements began to affect the right leg, and in this part convulsive movements often occurred every few minutes. The mother has observed that frequently these attacks are at once relieved by the act of micturition.

Dr. J. P. Crozer Griffith related the history of a case in which there had been symptoms of brain lesion, with peculiar movements of the limbs and face. In his opinion hysteria is often overlooked in children.

Congenital Cyanosis.

Dr. Griffith reported, among other cases, one of congenital cyanosis in a child who was 3 years of age, who had a history of having been subject to cyanosis during crying spells from the age of 3 months. The pulmonary second sound was greatly accentuated, but no murmur was heard. The exact lesion was not known, but it was suggested that there might have been an abnormal arrangement of the blood-vessels.

Gumma of Liver in Child.

Dr. D. L. Edsall reported a case of gumma of the liver occurring in a child 14 years of age. The speaker stated that gumma in late childhood has not been frequently reported. The condition has been repeatedly mistaken for leukemia or malignant growths. The father had possibly had syphilis; in the case of the mother, the history was negative. On admission to the St. Christopher's Hospital for Children, there was subcutaneous edema and effusion into the abdomen and pleuræ. On the left side of the abdomen a mass the size of the hand could be detected, and apparently was attached to the left lobe of the liver. Liver dulness extended to the navel and there was pain on pressure. Under the influence of specific treatment the mass on the left side became perceptibly diminished toward the second week, and at the end of one month had entirely disappeared. The liver, however, remained enlarged, and the renal symptoms present did not change.

Mastitis from Violence.

Dr. Emery Marvel reported a case of mastitis which had been due to infection from external violence. In this case the incision and drainage had given entire relief.

Dr. T. S. Westcott made a few remarks on the differential modification of the proteid of milk.

NEW YORK ACADEMY OF MEDICINE.

Meeting of the Section on Otology, held February 13.

Operation in Acute Mastoiditis.

Dr. E. B. Dench presented a paper on "The Early Operative Treatment of Acute Mastoid Inflammation." He said that while the presence or absence of fever is of no significance in adults as indicative of the condition of the middle ear and mastoid, it is a symptom of some value in children. The pain is usually, but not invariably, severe. Sleeplessness is one of the most important symptoms, and in any case of middle ear suppuration in which the patient is unable to sleep, whether or not this is attributed to pain, it is important to carefully investigate the condition of the mastoid. In his experience, tenderness of the tip of the mastoid has been present in almost all cases of acute middle ear inflammation occurring in the recent epidemic of grippe. Of the symptoms which warrant operative intervention, tenderness over the region of the antrum is the most reliable, but others must be present to warrant a resort to a mastoid operation. In any case, a narrowing of the deep meatus should be regarded as an exceedingly grave sign, and if it persists in conjunction with mastoid tenderness, the surgeon should not delay operating. A mastoid operation conducted in accordance with the principles of modern antiseptic surgery can hardly be said to be attended by any special risk. Sometimes a free incision into the membrana tympani at an early stage is all that will be required, but when it is evident that the mastoid is involved, the operation should be complete and thorough. The first step should be the opening of the antrum and the establishment of a free communication with the middle ear. The possibility of intracranial involvement in even the most acute cases is one argument in favor of this thorough operation being done in every instance. He would, therefore, operate on these cases very early, limiting all measures at abortive treatment to those seen in the earliest stage, and in which there is simply a fear that mastoid involvement will occur. When there is narrowing of the meatus and well marked mastoid tenderness he does not believe it is prudent to attempt to abort the inflammation; it is far better to keep the patient perfectly quiet and under observation, abstaining from using external applications, which would probably only serve to mask the symptoms. If at the end of twenty-four or forty-eight hours there is no change the surgeon should operate on the mastoid.

KINGS COUNTY (N.Y.) MEDICAL ASSOCIATION.

Memorial to Edward Robinson Squibb.*

Dr. John D. Rushmore, Brooklyn, presented this memorial: Dr. Edward R. Squibb was born in Wilmington, Del., July 4, 1819. His medical education was received in Philadelphia, at the Jefferson Medical College, and from this institution he was graduated in 1845. He began his medical career as a surgeon in the United States Navy, and those who knew him well can recall with pleasure the relation of his experiences on shipboard. To the end of his life he loved the sea, and no form of relaxation was enjoyed more by him or more beneficial to him than an ocean voyage.

In 1853 he was acting as surgeon in charge of the Naval Hospital in Brooklyn. He had at that time reached in line of promotion the position of past assistant surgeon in the U. S. navy. About 1863 he resigned from the navy, and failing to receive from the government sufficient funds to carry on the investigation and work necessary for the manufacture of pharmaceutical preparations, of which the government was in need, he established a private laboratory, and, to quote from the *Medical News*, "began what has been one of the most valuable life works that this country has known in the history of medicine, for it was medicine itself of which he was master. A chemist and a physician he was, but with all the keen desire of the true scientist to discover remedies and of the doctor to apply them to human ill. Instead of practicing at the bedside with the drugs the names of which he had learned in his medical books, he studied the drugs themselves chemically, physiologically, therapeutically, and sent them out to his brother practitioners in such form that the whole country, in fact the profession of the round world, accepted his dictum, and made his name the standard mark for purity and accuracy in pharmaceutical preparations."

It is fitting that the Kings County Medical Association should do all honor to his memory. He was one of its founders and in defense of the principles on which it is based he took a leading part nearly twenty years ago, when, with many others, he withdrew from the New York State Medical Society and subsequently formed the New York State Medical Association, of which this body is an integral part. He was a man of strong convictions, but no better evidence of his freedom from any strain of intolerance or prejudice can be furnished than his modest and temperate but firm defense of what at that time he thought was right; and his quiet accuracy of statement then, as always, was as far as possible from the blustering confidence that characterizes the support of a prejudice. The position which he took and maintained so sturdily alienated no man's affectionate regard for him, and some of those who differed from him then, bore willing testimony to his worth by their presence at the funeral service which, in its simplicity, accorded with his own wish. He was a member of The American Medical Association, New York State Medical Association, Kings County Medical Association, Metropolitan Museum of Art, the Philosophical Society of Philadelphia, and many other societies of like character.

His death, the immediate cause of which was cardiac dyspnea, occurred on the evening of Oct. 25, 1900, at his home. The following extract from an obituary notice published in the daily press is a touching and worthy tribute to his character: "The death of this well-known maker of medicines is the removal of a sturdy character, a fine thinker, an eminent chemist, and a strong, clear personality. Science, philanthropy, religion and citizenship have lost a bulwark and an ornament in him."

He was a great power in Brooklyn—out of sight. He never advertized. He never made addresses. He wrote only within the lines on the subjects and for the members of his own profession. He abhorred publicity and praise. Yet his influence on medicine, on medical thought, on medical practitioners and sympathetically on public health was not unlike that of the Gulf Stream on climate or of the Nile on soil. Men and women lived and labored, died and won renown here who never knew of him. But those who knew Brooklyn to its elements, to its foundations, who knew medicine to its causes and beginning, knew that this quiet, true, diligent man, this incarnated conscience and this great embodied capacity was veritably a genius, truly a world benefactor, one whom the giants and the literature of medicine round the earth held in almost worshipful veneration.

He was a martyr as well as a marvel of science. Over a generation ago, his devotion to his calling subjected him to injuries from an explosion, by which his life was long in danger, his sight long threatened and his visage permanently and sadly marred. The latter misfortune was the only one that did not pass away. He bore it with dignity, philosophy and fortitude. It increased his congenital aversion to public occasions, but it, by reflex action, sweetened to him the society of friends and the comforts of literature and thought. It in nothing affected, except to confirm and augment, his faith in the Divine Goodness, giving as it did, to him, a cross to bear, which he bore in the spirit and love of the Master. To those aware of the causes and of the ordeal, this affliction made his career replete with the power of pathos and eloquent with the pathos of power.

---

* Published by special request of the Kings County (N. Y.) Medical Association.

Long ago a wave of adversity rolled over and prostrated this extraordinary man. His medical brethren quietly put him on his feet with a love gift that enabled him to start the world again. His rehabilitation was essential to their sense of security in their own work. Their gift to him was a debt, they felt, not a gift, and not a loan. Not so felt he. As soon as he could, he returned it all with interest to the full. He would owe no man anything, even by implication. His exquisite act of honor has been within the knowledge of the descendants of those whom it was tendered for over a generation. It is permitted to tell it now that he is dead. Said Goethe: "The spirit in which we work is the chief matter." The spirit in which E. R. Squibb worked was worthy of the best ideals of duty and consecration to humanity.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment will be answered in these columns.]

Treatment of Blepharitis.

Pyle, as noted in the *Phila. Med. Jour.*, states that two much attention can not be given to the causal conditions; careful attention to refraction, and any disturbance of the oculomotor apparatus should be remedied. If chronic conjunctivitis co-exists, which is the rule, a mild stimulating astringent should be used. He recommends the following:

℞.	Acidi borici	gr. xlv	2	66
	Sodii chloridi	gr. x		66
	Zinci chloridi	gr. ii		12
	Aq. destil	℥iv	128	

M. Sig.: A few drops to be instilled into each eye three times a day.

He states that all scales and crusts should be carefully removed, morning and night. Absorbent cotton moistened with warm water, warm boric-acid solution or warm bichlorid of mercury solution—1 to 5000—may be used to loosen the accumulated secretions. Any underlying ulcers should be cleansed, the cilia epilated, and the cavities painted with a 2 per cent. solution of silver nitrate. The application of a fatty substance facilitates removal of crusts, softens the skin and prevents further occlusion of the glands. For this purpose he advises the following:

℞.	Hydrargyri oxidi flavi	gr. i		06
	Vaselini	gr. iii		18

M. Sig.: Rub in thoroughly a piece the size of a matchhead each morning and night, after having removed the crusts, dried secretions, etc.

Prevention of Gastric Fermentation.

Ewald recommends the following:

℞.	Resorcin—resublimed	gr. lxxv	5	
	Bismuthi salicylatis			
	Pulv. rhei rad.			
	Sodii sulphatis, āā	ʒiiss	10	
	Sacchari lactis	ʒiv	16	

M. Sig.: One-half teaspoonful twice daily.

Ointment for Chapped Hands.

℞.	Hydrarg. oxidi flavi	gr. ii		12
	Balsami Peruvianæ	gr. x		66
	Vaselini	℥ss	16	

M. Sig.: Apply locally night and morning. If there is itching present two grains of carbolic acid may be added.—Hearn.

For Constipation with Flatulence.

Illoway, in *New Orleans Med. and Surgical Jour.*, recommends the following combination:

℞.	Ext. Colocynth. comp.	gr. 1/3		02
	Terebinthinæ—Venice	gr. i		06
	Pulveris aloes Soc.	gr. iss		09
	Ext. nucis vomicæ	gr. 1/4		015
	Ext. hyoscyami	gr. i		06

M. Ft. pil. No. i. Sig.: One such pill twice daily.

Treatment of Acute Gonorrhea.

Dr. Cabot, in *Med. News,* states that if cases come to him for treatment during the first twenty-four hours, they can be greatly relieved, and the gonococci made to disappear from the discharge in the course of a few days. The following silver salt is used:

R.	Argonin	gr. lxxx-ʒiiss	5-10	
	Aq. destil. q. s. ad	℥iv	128	

M. Sig.: Use as a deep injection into the urethra.

Six drams of the solution should be employed and retained within the urethra, first instructing the patient to urinate and wash the urethra out with a warm solution. Other treatment consists in the use of the following internally:

℞.	Potassii citratis	ʒvi	24	
	Aq. destil. q. s. ad	℥iii	96	

M. Sig.: One teaspoonful in water three times a day.

Where the case presents a copious discharge the following is given:

℞.	Plumbi acetatis			
	Acidi tannici			
	Zinci sulphatis			
	Cupri sulphatis, āā	gr. ii		12

M. Ft. tabella No. i. Sig.: Dissolve one such tablet in four ounces of water and use as an injection after each urination. The importance of the temperature of the injection is emphasized, and he recommends the injection to be given at a temperature of 110 F.

Treatment of Pulmonary Tuberculosis.

The following prescriptions are very adaptable in treatment of pulmonary tuberculosis:

FOR THE SEVERE COUGH.

℞.	Codeinæ	gr. iii		18
	Dionin	gr. vi		36
	Acidi hydrocyanici dil	ʒi	4	
	Spts. vini Gallici	℥i	32	
	Ext. glycyrrhizæ	ʒi	4	
	Syr. pruni Virginianæ q. s. ad	℥iii	96	

M. Sig.: Shake well and take a teaspoonful three or four times a day.

Dionin is a preparation derived from morphin. It is a white crystalline powder, soluble in water and can be used subcutaneously. It contains some of the narcotic principles of morphin, but not to such a degree. It is recommended in same doses as codein and can be used in tuberculosis and bronchial affections.

FOR THE SYSTEMIC TREATMENT.

R.	Creosoti—beechwood	ʒii	8	
	Glycerini	℥i	32	
	Spts. vini Gallici	ʒvi	24	
	Tinct. gentianæ			
	Tinct. cinchonæ comp. āā	℥iii	96	

M. Sig. One teaspoonful four times a day.

W. J. Robinson recommends that each time the mixture is repeated one dram of creosote be added until one ounce is added. The patient thus commences with two minims of creosote per dose and reaches eight minims.

℞.	Creosoti	ʒi	4	
	Guaiacol	ʒii	8	
	Emul. ol. morrhuæ—50 per cent.	℥xii	384	
	Syr. hypophosphiti—U. S. P.	℥iv	128	

M. Sig.: One tablespoonful three times a day.—*Merck's Archives.*

Treatment of Acute Bronchopneumonia in Childhood.

The Medical Record gives the following outline of treatment by Carriere: Isolate the patient as much as possible, avoid chills, and make the air which the patient breathes aseptic by antiseptic vapors. For this purpose he recommends the following:

℞.	Phenol	ʒv	20	
	Thymol			
	Benzoin, āā	ʒiiss	10	
	Alcoholis	℥iii	96	
	Aquæ	Oiss	768	

He also recommends keeping the respiratory tract in good condition by nasal douches and mouth washes of boric acid, keeping the skin in good condition, keeping the gastrointestinal tract in order by the administration of mild chlorid of mercury. As alimentation he recommends a glass of milk every two hours; bouillon or beef juice to children over eighteen months.

Rhus Glabra in Enuresis.

Dr. J. J. Cassidy states, in the *Canadian Jour. of Med.*, that rhus glabra will prevent incontinence of urine in children. He prescribes it in the following form:

℞.	Ext. *rhois glabræ flu*	ʒvi	24	
	Syrupi simplicis q. s. ad	℥ii	64	

M. Sig. One teaspoonful at bedtime. He states that the use of iron as an adjuvant to rhus is important; but the mineral being incompatible with this vegetable astringent he gives it in a separate mixture along with cascara to relieve constipation, and lactophosphate of calcium to relieve irritative dyspepsia. He recommended the following:

℞.	Ferri citratis	ʒiiss	10	
	Syr. calcii lactophosphatis			
	Elix. cascaræ sagradæ—arom.—āā	℥ii	64	

M. Sig.: One teaspoonful after the noon meal.

The action of rhus glabra resembles tannic acid. The astringent action of the former is exercised upon the bladder.

To Check Hemoptysis.

A. Hecht has employed with success the following pill. in checking hemoptysis in tuberculosis:

℞.	Extracti ergotæ	gr. xxx	2	
	Pulv. digitalis fol.			
	Ext. hyoscyami, āā	gr. xx	1	30
	Quininæ sulphatis	gr. xxx	2	

M. Ft. pil. No. xx. Sig.: Three to five pills may be taken daily. He believes that the real virtue of this combination in producing hemostasis lies in the quinin reinforced by the digitalis.

Lime Burns of the Eye.

W. C. Posey, in the *Ther. Gazette*, states that after removal of all the irritating substance. the lids should be everted and every part of the conjunctiva carefully cleansed with oil or a diluted solution of vinegar. or water alone may be employed. Sugar is sometimes used in concentrated solutions. as cane sugar forms an insoluble compound with lime. Following the chemical neutralization the eye should be thoroughly cleansed with a boric-acid solution, 10 grains to the ounce, and ice compresses constantly applied until all inflammatory reaction has subsided. As there is danger of involvement of the iris, if the cornea is affected a solution of atropin should be dropped into the eye to dilate the pupil, and subsequently the use of olive-oil or castor-oil dropped into the eye will best promote the healing.

Treatment of Chalazion (Stye).

Stazmenski states that the cause of the affection consists in the penetration of microbes into the meibomian gland. The treatment he employs consists in applying the following ointment upon the skin surface of the chalazion and gently rubbing it in every night at bedtime:

℞.	Iodi (pure)	gr. xii		72
	Potassii iodidi	gr. xxxvi	2	36
	Vaselini	ʒi	4	
	Aq. destil.	ʒi	4	
	Lanolini	℥ss	16	

M. Sig.: For local application.

Treatment of Influenza.

W. H. Thompson, in the *Med. Record*, advocates the use of the following pill:

℞.	Ext. aconiti	gr. 1/12		005
	Pulveris opii et ipecac	gr. ss		03
	Phenacetini	gr. ii		12
	Quininæ sulphatis	gr. iss		09

M. Sig: Two such pills to be taken three times a day as long as the fever continues. The dosage is then to be reduced to one pill until the catarrhal symptoms have passed away.

For the coryza and nasal symptoms he recommends the following:

℞.	Ext. belladonnæ	gr. 1/4		015
	Camphoræ	gr. ii		12

M. Sig.: One such pill as necessary.

FOR THE PERSISTENT COUGH.

℞.	Ammonii bromidi	gr. xx	1	33
	Antipyrini	gr. x		66

M. Ft. Chartula. Sig.: One powder once or twice daily.

Phosphate of Calcium in Scrofulosis.

Hare recommends calcium phosphate in suppurating scrofulous ulcers. Owing to its more ready solubility, he prescribes the lactophosphate of calcium in the following combination:

℞.	Syrupi ferri iodidi	ʒi	4	
	Olei morrhuæ	℥i	32	
	Syr. calcii lactophos.	℥i	32	
	Aquæ calcis q. s. ad	℥iv	128	

M. Sig.: Shake well and take from two to three teaspoonfuls after each meal.

Medicolegal.

Five Dollars for Postmortem Examination.—Section 4936 of the Alabama Code provides that a physician or surgeon, who has been subpenaed to attend an inquest, shall be allowed, as a witness, $5, with $1 additional for each mile he may have traveled in attending such inquest, to be collected out of the estate of the deceased, if solvent, and if insolvent, to be paid out of the county treasury. Section 4573 provides that, if the immediate cause of death is uncertain, a physician or surgeon may be summoned to make a postmortem examination, who shall give his opinion in writing as to the cause of death, and shall be entitled to the same fee and mileage, to be paid in the same manner, as for attending an inquest, etc. Each of these sections, the Supreme Court of Alabama says. in the case of Naftel vs. Montgomery County, relate to the same subject-matter, and are to be construed together. But one fee is allowed the physician or surgeon for attending an inquest and giving his professional opinion after examining the dead body, however much labor or skill it may have required. and the fee, therefore, is specifically prescribed. If it be said that this allowance is inadequate, a full answer to the suggestion is that the legislature has prescribed this and no other fee for such services. It often occurs in rendering services to the state and county, that the citizen is inadequately compensated in money, notably in the cases of jurors and witnesses. whose fees, as allowed by law, in many instances, fall short of their actual expenses, to say nothing of the value of their time. their trouble. and losses in business. Their compensation comes mainly from the services they render the county in the interest of law, order and good government; and so does the physician's or surgeon's, when he bestows his skill in the duties required of him in holding inquests, in the interest of the discovery of unlawful homicides and the punishment of the perpetrators of them. In this case, the plaintiff stated at an inquest that he could not give a professional opinion as to the cause of death without holding an autopsy. Thereupon he was directed to hold the same and to make a microscopic examination of the organs of the deceased, which were reasonably necessary to be made in order to determine whether or not death resulted from foul means. Pursuant to such directions from the coroner, he performed an autopsy and made a microscopic examination of the organs of the deceased, being engaged in and about the same for one day and a part of another. The reasonable value of such services in making such autopsy and microscopic examination was fixed at $50. He was paid $5 therefor, by the administrator of the estate of the deceased, and now the Supreme Court of Alabama holds, under the doctrine above stated, that he received the fee allowed him by law, and was entitled to no more.

Could Do No Less than Resuspend Unvaccinated Pupil.—In the South Dakota case of Glover vs. the Board of Education of Lead, the suspension from school, on the 17th of the month, of a pupil who refused to furnish satisfactory evidence of vaccination, was followed by mandamus proceedings. At the hearing, it was tacitly conceded by the board that at and prior to the time the boy was suspended there was no case of smallpox in the city or county, and that its order requiring vaccination was needless, and without justification, as a sanitary or preventive measure, and was issued without cause and without authority of law, and was unjust and oppressive. Upon this admission, and with consent of the board's counsel, a peremptory writ of mandamus was issued, on the 2d of the following month, commanding the school board and superintendent to immediately admit the boy to the public school, as a pupil, without requiring of him a certificate of vaccination or compliance with the order of the board of education requiring pupils of said schools to be vaccinated. Conformable to this mandate, the boy was permitted to return to school, as a pupil, on the 5th. But, in the afternoon of that same day, he was presented with a notice from the superintendent stating that, by order of the board of education of the 3d instant, he was refused admission as a pupil of the public schools of the city until he presented satisfactory proof of his vaccination against smallpox. Thereupon contempt proceedings were begun, based upon the alleged violation of the peremptory writ of mandamus mentioned. The defense was that subsequently to the service of the writ, and before the boy had been readmitted to the public schools in compliance therewith for a day, most alarming sanitary conditions were officially brought to notice by the service of resolutions and orders of the state, county and city boards of health, respectively, showing that smallpox was then prevalent in the vicinity of the city, and requiring the health authorities to exclude all children and pupils from the public schools who failed or refused to furnish satisfactory evidence of vaccination. Under these circumstances, the Supreme Court of South Dakota holds that there was no contempt. In view of the action taken by the various boards of health, no less, it says could be done, and the penalty of the law be escaped. While the earlier resolution was in effect nullified by the mandamus complied with, further proceedings on the part of the board of education, under justifiable conditions, were not forestalled for all time, and the fact that an emergency immediately arose requiring prompt action for the protection of the public from the consequences of a dreadable disease in no manner rendered the board guilty of contempt. The temporary regulation, requiring children to furnish satisfactory evidence of vaccination or remain away from school until the further order of the board, was reasonable, and within the general power of the school board to control, manage and regulate the public schools of the city. Independently of express legislation, a board of education has power, under circumstances like these, to close the schools until the danger subsides, or suspend such as refuse to undergo vaccination.

Concerning the Pennsylvania Medical Practice Act.—The Pennsylvania act of May 18, 1893, the Supreme Court of that state holds, *in re* Campbell, is a valid and constitutional exercise of the police power of the state upon a subject plainly within that power, and urgently in need of control by it. The title of sixty-two words it is certain is not open to criticism for brevity or vagueness. But it says that the purpose of the act is indicated in the phrase "to regulate the practice of medicine and surgery." This gives notice to any one desiring to enter the practice that its provisions do or may concern him. Nothing more is required. Nor does the court consider that the act is in contravention of the provisions of the state constitution vesting the appointing power in the governor, because, it holds, there is nothing in the constitution which prohibits the legislature, in creating an office, from fixing the qualifications of the incumbent and thereby limiting the choice of the governor in the appointment to the class of persons so qualified, which is all this act does in regard to the offices which it provides for. Neither does it think that the act violates the constitutional prohibition against any local or special law "granting to any corporation, association, or individual any special or exclusive privilege or immunity." It says the act is not local or special. It embraces the whole state, and applies to all persons of every school or system of medicine desiring to enter on the practice. The designation of the three medical societies from whose members the board of examiners are to be selected is not the grant of any special or exclusive privilege to those societies, but a convenient method or securing a competent and qualified class from whom the examiners may be selected. But, even if it should be regarded as a special privilege to those societies, it would not be unconstitutional. The board of examiners are state officers, charged with the administration of the state's police power on the subject of admission to the practice of medicine. The constitutional provision quoted does not apply to such officers. The state may choose its own agents in its own way to carry out its commands in regard to the taxing or police or other general powers. The act, the court further holds, by clear implication provides for registration by entry of record in a county medical register kept by the prothonotary. This register, while not a judicial record, is a public record of matters of public interest and concern, directed to be kept open and accessible for the information of the public, put from motives of public policy under the sanction and control of the court, the duty of so keeping it being imposed on the prothonotary as an officer of the court, in the performance of which duty he is necessarily subject to the orders and control of the court. So, if a licensed physician applying for registration should be refused without good reason, the court, on mandamus or by summary order, would compel its officer to perform the duty laid upon him by the statute: and if he has, through misinformation, made an erroneous entry not warranted by law, the court has power to compel its amendment or cancellation. It is immaterial that he who petitions to have the record corrected should have no personal interest in the matter. It is also irrelevant to a proceeding to have a medical register corrected by striking off a name that on a trial for practicing medicine in violation of the statute the person whose right to registration is questioned was acquitted, it being charged that the entry was procured by falsehood and fraud.

AMERICAN.

1. **Gastro-intestinal Hair Cast.**—Jacobson reports and illustrates a hair cast of the stomach, extracted from a child 11 years old, who had been in the habit of swallowing her hairs. The symptoms were colicky pains, especially at night, constipation, gastric disorders, etc. The diagnosis was not clear by physical examinations, and exploratory operation was performed. The cast was peculiar in its showing a superior curve, almost rectangular. The author reviews the literature of similar cases at length, and calls attention to the fact that while the operation in cases where it was found was always experimental and exploratory, or was performed with the expectation of finding other conditions, the patient has in every case made an uninterrupted recovery.

2. **Infantile Scurvy and Rickets.**—The recognition of scurvy in young children is comparatively recent, the earlier errors in diagnosis being largely due to the fact that the principal symptoms confused it with articular rheumatism and the characteristic symptoms of petechiæ, spongy gums, etc., are not always present. The peculiar characteristics of scurvy in infants are the very grave appearance of the child in its severe forms, the rapidity with which it recovers under proper treatment and the rarity of fatal termination. Three cases are described illustrating the different types of the disease, one in which spinal disease was diagnosed, another where meningitis was suspected and the third case where the child suffered from almost complete paraplegia with the characteristic scorbutic symptoms. Hare remarks also on the fact that scurvy is a disease of the well-to-do, while rickets is a disorder of the poor, and he believes that the latter is largely due to general deficiency of nutrition and defective development rather than to any lack of the proper constituents in the food.

3. **Tuberculosis.**—The house problem in tuberculosis is treated of by Guerard, who notices the unhygienic conditions in tenement houses, lack of ventilation, overcrowding, etc. The facts are given as regards houses where tuberculosis seems to be a permanent infection, and he expresses the opinion that in some cases it may be that only destruction of the tenement will suffice to destroy the germs. The rules which should be followed as regards housing, sufficient air space, baths, and the hygienic problems generally are noticed. The author concludes his paper with a discussion of the financial aspects of the case, the money lost, loss of work, sickness and loss of life.

4. **Lupus.**—Varney has found the most satisfactory surgical treatment in lupus to be the curette, with which one can clear away the broken-down cheesy, degenerated tissue, leaving the healthy tissue as a foundation for growth. Electrolysis, in the few cases he has tried it, has given good results. Nitrate of silver is a valuable remedy, also arsenical paste which destroys diseased tissues only. Pyrogallic acid is also mentioned, but the special object of his paper is to present the therapeutic value of the *x*-ray, pointed out by Dr. Pusey, of Chicago. It has various advantages, it is painless, the exposure is short, and the area may be completely controlled. He reports a case in which this method was employed with good results.

9. **Woolen Yarn Truss.**—The use of the woolen yarn truss in infantile inguinal hernia is recommended by Boland, who gives directions for making it, as follows: "Measure with a tape line the distance around the child on the plane of the pelvic inlet, beginning with and coming back to the hernia, then carry the line down on the perineum and up and out in the gluteofemoral crease and almost to where it would touch the girdle part. Mark this length on the woodwork of the door or window casing, and at each end of it drive in a three-inch nail half-way to the head. Over these nails wind the worsted, previously rolled from the skeins as bought, just tight enough to keep from kinking, and use thirty to forty threads according to size and strength required. Remove the skein, tie in the two loose yarn ends, and in one end loop a foot of white tape, and the truss is ready." For applying it: "Carry it around the child with the long end at the affected groin, pass this longer end through the other loop and draw the long end down under the corresponding thigh and out and up in the gluteofemoral crease and tie the tape to the girdle. . . . The doubled and loosely twisted yarn is so elastic that it will keep up a constant hug that will make up any slack made by the motion of the child." He sums up his paper by saying that the use of some retentive will hasten and insure the natural tendency to cure. The worsted truss is easily made to measure at the bedside, is cheap, comfortable, can be worn by any infant, but with this as with any other truss vigilance and intelligence must counteract the associated causes of hernia.

10. **Disinfection in Diphtheria.**—Veeder notices the possibility of infection of physicians treating cases of diphtheria, and advises the use of precautions. The routine he has adopted is: to be provided with squares of antiseptic gauze and corrosive sublimate tablets. A square of such gauze can be held over the mouth and nostrils with the left hand while the right is free to use the tongue-depressor and swab. Both hands and face should be wet with sublimate solution before and after examination, and the gauze be burned after use. This, together with frequent spraying and cleansing of the mouth, throat and

nostrils, and bacteriologic testing, offers a very complete security against receiving or carrying infection. He notices the diphtheroid or staphylococcic sore throat as being the favorite tract for diphtheria infection, therefore all diphtheroid throats should be considered as suspicious.

15. **Pneumonia.**—No routine treatment for pneumonia exists, but there are many approved therapeutic measures. Among these Crook mentions the patient's surroundings, a cheerful, well-ventilated room with temperature between 65 and 72 degrees, digestible liquid food and cold applications to the chest. Poultices are not much advocated of late, blood-letting is coming more in favor in florid cases and where the heart is seriously embarrassed by the pulmonary obstruction, or cyanosis or dyspnea prevails. The hypodermic injection of saline solution in connection with the blood-letting is advised by Michel. Arterial sedatives are less favored than formerly, though they still have some advocates. Routine purgation and antipyretics are generally condemned, and the profession is still at variance to some extent as regards the use of opiates. Crook thinks that on the whole they should not be resorted to until insomnia, pain or restlessness renders them necessary. Alcohol is losing favor and the weight of opinion is against the use of digitalis. Oxygen inhalations are safe, but their usefulness is disputed. As regards specific medication to destroy the pneumococcus in the blood, there is some evidence of the value of the salicylates, creosotal and the silver salts internally. Serumtherapy of the disease is still in the experimental stage, a standardized serum is not yet available, and the progress in this direction during 1900 has been very slight.

16. **Periodical Insanity.**—According to Defendorf periodical insanity is one of the most frequent of morbid psychoses, readily diagnosed in first attacks and not associated with any rapid general mental deterioration. The prognosis is not good as the attacks are likely to recur with varying intervals, throughout the patient's life.

17. **School Inspection.**—Greene describes the system of medical examination of school children in Boston. The inspectors are generally chosen from among the younger members of the profession and, though the pay is small (only $200), the positions are honorable and desirable and may indirectly help in building up the physician's practice. Monthly reports are required to the secretary of the board of health, which generally supervises the work. An association of inspectors has been formed, presided over by the chairman of the board, for aiding in the work by profitable discussion or to further mutual co-operation. Children suffering from contagious diseases and those from non-contagious but more or less disabling disorders are especially the objects of inspection; the inspectors are provided with diphtheria culture outfits, and every precaution is taken against possible contagion. Children affected with tuberculosis are advised to stay away from school, though it is not said that they are excluded. The vision of pupils is another important subject investigated, and where defect appears the parents are advised to consult oculists. Still other advantages from the inspection have been the calling attention to points of cleanliness, etc.

18. **Tetanus.**—Bissell reports two cases of tetanus following apparently clean surgical wounds. He is inclined to suggest a long-latent, old infection to account for the disease here, and refers to cases reported by Kaposi, Cheeseman and others as supporting this view.

19. **Adhesion of Soft Palate.**—Koenig's case was one of adhesion of the soft palate to the posterior pharyngeal wall, producing complete nasal obstruction. The condition was entirely relieved by operation under local cocain anesthesia. After the operation a gauze plug was used for the first two days, and then it was replaced by a hollow silver plug fitted to the cavity, through which nasal breathing was possible. Healing was complete in three weeks.

20. **Erysipelas.**—Keirle reports great success in the treatment of erysipelas, according to the following *plan:* The affected area is first *enclosed* in a painted ring of tincture of iodin. The ring is not to be started *at* the margin of the reddened area, but 2 *to 3 inches from it*, and a sufficient number of coats should be applied to cause a slight desquamation of the skin. At the same time the whole surface enclosed in the ring is to be covered with an ointment of ichthyol, about 1 dram to 1 to 2 ounces of vaselin. This is covered with a piece of gauze and a hot stupe applied and changed about every four hours. At the end of twelve hours the ichthyol ointment is washed off and a fresh coat applied, and if the iodin has not had sufficient effect, one or more new coats are applied. Internal treatment may or may not be instituted, as the result is the same in either case. Although both iodin and ichthyol are used in the treatment of erysipelas the author has not heard of any cases treated as above. Three or four days of this treatment have not failed to stop the trouble, the inflammation not crossing the painted line of iodin except in one case; in which another ring painted further out, and the same treatment as at first effectually stopped the spread of the trouble. He does not claim originality for this treatment, but can not remember seeing it described elsewhere.

21. **Stethophonometry.**—Abrams remarks in regard to the difficulties of testing the different degrees of intensity, etc., of sounds and the methods of their measurements. The method by the use of rods, which was reported by him in an earlier article, is inconvenient and somewhat impracticable, and the other method, by measuring by different points of the chest to which the sounds are conducted, is relatively inaccurate. He has, therefore, devised a *stethophonometer*, which he illustrates. It is constructed on the disc-valve principle and is composed wholly of hard rubber. There are three perforated discs in its composition, the middle disc being made to revolve by means of a handle attachment, so that its opening may be made to approach or recede from the opening in the other two discs, thus increasing the resistance to transmission of the sound wave. On the face of the disc nearest the auscultator is a scale by which the intensity of the chest sounds may be measured. On one side of the disc the bell of the stethoscope is fixed and on the other side a plug, the size of which may be varied to fit any stethoscope. This plug is perforated and in the perforation may be fitted a rubber cork, if necessary, to offer still further resistance to sound. This, however, is rarely necessary. This stethophonometric attachment can be easily removed when found necessary to use the stethoscope in the ordinary method.

23. **New Ophthalmometer.**—Aiken describes a new ophthalmometer which he thinks offers practically as favorable results, at less expense, than the original expensive and bulky instrument employed.

24. **Combined Gynecologic Operations.**—Sutton notices the fact that some years ago it was customary, when double operations were required, to make only a single one at the time with the result that the patients were sometimes laid up for weeks or months or recovering from one operation only to pass into another. He points out that of late it has become customary to do a number of operations under one anesthesia, and he reports fifteen cases and the time employed in each. Various operations, such as curettage, tracheotomy, craniotomy, laparotomy, etc., are all performed at once.

26. **Buboes.**—After describing the anatomy, pathology, diagnosis, etc., of the various forms of buboes, Griffith details his own treatment, which is to hurry up the formation, using hot fomentations, and when suppuration is demonstrated by fluctuation, puncture and wash out, using thorough syringing with hydrogen dioxid and inserting a drain. Dry dressing is applied, sufficient to absorb the discharge. The next dressing and washing should be done in twenty-four hours, and after that at intervals of two to four days. The hygiene of the patient should be looked for. Alcohol, fried, greasy, and indigestible foods should be avoided. He does not offer this as an original method of treatment, but it is one that has met with success in his hands and which has his approval.

28. **Appendicitis.**—The conditions of appendicitis are described in detail and very completely illustrated by Abbe. There is evidence that the stone does not begin to form until

the stricture has contracted to so small a caliber that the exfoliated epithelium is unable to pass into the colon in the ordinary way. This debris of epithelium, irritating by its presence, begets proliferation, pus cells, etc., and sets up the mischief in the appendix. The structure of concretions in all the cases he has found has been epithelial, though rarer cases may occur when food particles may be their basis. He holds that the attack of appendicitis recognized by the patient is in most cases the end of the disease, the stricture having existed for many years. As regards the difference between medical and surgical treatment, there is no doubt that many do get well under medical care alone, but the surgeon can say that the vast number of so-called medical cures are mild attacks and the disastrous ones only rarely give spontaneous cure. This may occur with ulceration into the bowel or even the bladder. He discusses the recuperative power of the stomach under special conditions, the life of the cells, etc., at some length.

29. **Cardiac Compensation.**—Manges reviews the cardiac disorders in regards to the question of compensation, and sums up by stating that hearts which have been attacked by actual organic valvular diseases from any cause have no longer an absolutely normal myocardium, since the latter has been involved in various foci. Any defect in the valvular apparatus is compensated for a longer or shorter period by hypertrophy, which in turn is followed by changes in the parenchymatous muscle cells, of interstitial connective tissue, or both, or in the ganglion cells or the nervous fibers, or both, which may finally result in such a weakening of the heart walls that the organ is no longer able to propel the blood in normal amounts, as needed by the system. The causes of this may be either one or both, distention of the cavities from leakage of the valves or it may be due to defective nutrition or myocarditis, myocardial sclerosis, anemia, chronic or acute intoxications, mechanical overstrain or other causes. If nutrition of the heart is maintained and the work it is to do regulated in time, these myocardial changes will not exert any deleterious action on the cavity, but may be even conservative to the heart as such until the appearance of arterial sclerotic changes to which all parts of the body are ultimately liable. The hypertrophied heart is more liable to arterial sclerosis of the coronaries and chronic myocarditis, yet with proper care for good nutrition and the work of the heart the disease may be controlled for a long time. The most important causes of lack of compensation are here reviewed in detail. The first of these is anemia, the most potent and common, together with infections; then disturbances of local nutrition, of which coronary arterial sclerosis is the most important and serious; and again, increased work of the heart due to overstrain, parturition, alcoholic excesses, tobacco excesses, etc. Purely functional cardiac disturbances as causes of decomposition are rare; marked mental excitement may produce rises in the arterial pressure acting in this way. Death from broken hearts may be accepted as an actuality. Finally, he maintains as a separate group those unfortunate cases where the improper administration of cardiac drugs, for example the use of digitalis, and at present the abuse of the Nauheim method and exercise, causes failure in compensation. He has seen such cases.

30.—See abstract in THE JOURNAL, xxxv, p. 1172.

31. **Spinal Curvature.**—Freiberg emphasizes the importance of spinal curvature, its effect on nutrition, general health, displacement of viscera, and impairment of the muscular system, and the fact that it shortens the expectation of life. He then passes on to its treatment, pointing out that it is rotary lateral in its character, and that forcible correction alone is not the proper method for its treatment. Mobilization of the spine is the one thing to be striven for, and it implies the attainment of an over-correction if possible. The methods and apparatus are described. The development of the chest is the next indication which is suggestive of gymnastic work with or without apparatus. If it is to be accomplished by these measures, the development of all the muscles is important. The author recommends the Swedish system of gymnastics, but suggests avoiding all complicated movements, especially the lateral flexions. In some severe and resistant cases we are not successful in getting satisfactory results by these methods; of others, he has had experience thus far only with the Bradford and Brackett method for the forcible correction in such cases, and the results seem to have been encouraging.

Resinol.—In the notice in THE JOURNAL, of February 9, ¶29, p. 403, of Dr. Reynold's paper, resinol was credited with the effects which the author stated were due to subiodid or oxyiodid of bismuth, which he considered almost a specific in diseases of the gastro-intestinal tract. Of course, the use of resinol internally under such conditions could not be indicated.

34. **Influenza.**—From his own experience, personal and professional, Shields believes influenza to be transmitted directly from person to person, and that the first symptoms in the epidemic exhibit themselves either as bronchitis or coryza or an attack of rheumatism, the respiratory symptoms appearing later. He has never seen gastro-intestinal symptoms occur as the primary phenomenon. Of the nasal sinuses, the frontal is the most frequently affected, causing violent headaches. He insists on the importance of the recognition of the transmissibility of the disease. The drugs which he relies upon are: 1. Quinin, which kills the bacillus. 2. Calomel; a few large doses given in the beginning of the disease seems to ameliorate the symptoms markedly in many cases. 3. Iodin, especially in the form of hydriodic acid. For the nervous depression he has found phosphorus more valueble than strychnin. He thinks that benzoate of soda may be of some advantage, though he does not speak of it from personal knowledge. Muriate of ammonia has been his standby for the bronchial symptoms, exerting also its good effects upon the liver. The coal-tar preparations, he thinks, may have unfortunate effects, and he has placed more reliance upon opium or codein as an analgesic.

35. **Congenital Pyloric Stenosis.**—The case reported by Nicoll is that of a child 5 weeks old, which had been born healthy and remained so for about a week, excepting that in about fifteen to twenty minutes after each meal he vomited the entire contents of his stomach. No symptoms of dyspepsia, but gradual emaciation from lack of nourishment, appeared and the dilated stomach stood out on the attenuated abdominal wall, showing marked peristaltic waves. After some hesitation an exploratory operation was made and the pylorus found represented by a bulky ring of muscular or fibroid tissue. A pylorectomy appeared useless in the child's feeble condition, and, therefore, an incision was made above the ring in the stomach wall, and he performed a Loreta operation; a divulsion, from within, of the constricted pylorus was performed. The infant made a perfect recovery and has had complete relief from the previous trouble; excepting a slight rickety tendency, he is now, twelve months later, in perfect health. The author discusses the symptoms of the condition, the apparent cause of the vomiting, progressive emaciation, physical signs of the stomach with emaciation of the abdominal walls, the prognosis of the condition, its treatment and the theories of its causation. As regards treatment, only surgery gives a hopeful prognosis. As regards causation, the theories of congenital developmental aberration, of hypertrophy of the muscular walls of the pylorus, spasmodic contraction from gastric irritation, and chronic inflammatory processes are noted, but no positive opinion expressed. The important element in the cases is that of diagnosis; the trouble may be taken for infantile marasmus.

38.—See abstract in THE JOURNAL, xxxv, p. 1361.

50. **Diphtheria.**—This disorder was one of the most fatal diseases in Boston, the mortality being from 30 to 50 per cent. until the introduction of antitoxin, when it became a comparatively insignificant factor in the death-rate. Burrows' article gives a tabulated statement of about 2,000 cases of diphtheria, in regard to their mortality, ages, etc. The death-rate decreases from infancy to adult life. In the great majority the diphtheritic membrane was observed in both tonsils, and often elsewhere. There were 71 cases of nasal diphtheria. He insists on the importance of taking early cultures, but not waiting for their development before administering antitoxin. In 65 per cent. of the cases there was some form of cardiac dis-

turbance. The total number of cases of cardiac murmur was about 50 per cent. of the whole. The pulse is almost always feeble; acceleration and rapid pulse after the initial period means a guarded prognosis, and demands continued rest in bed. The use of antitoxin has made albuminuria rare; in 1757 cases, in none was there more than 1/4 of 1 per cent. found. There were 337 cases of laryngeal stenosis, 213 of which were intubated and 124 recovered with antitoxin alone. Of the 213 intubated, 96 died, 37 within 24 hours after admission into the City Hospital; and 40 during the acute stage, from toxemia. In 3 cases subsequent tracheotomy was performed, but all 3 died. He believes that the experience here obtained leads to the conviction that primary tracheotomy no longer has any place in the treatment of simple diphtheritic laryngeal stenosis. Complications, such as enlargement of the glands, ear disease, paralysis, etc., are noted. A large proportion of the fatal cases were moribund when received. There was a total of 240 deaths, 172 or 71.6 per cent. during the acute stage of the disease; in 131 cases there was a mixed infection. As regards treatment, antitoxin was the standby, but the author emphasizes the value of alcoholic stimulants, hot packs, and rectal feeding in cases where vomiting occurs. The experience teaches that the treatment can be best done by giving antitoxin early in large doses and at frequent intervals, especially in severe cases.

51. **Acute Interstitial Nephritis.**—From a study of three cases, the second occurring after an abortion, the first with general streptococcic infection, and in the third case, otitis media with bronchial pneumonia of streptococcic origin, Howard has been able to confirm Councilman's observation of the occurrence: 1. of plasma cells, lymphocytes, polymorphonuclear leucocytes in acute interstitial nephritis. 2. The presence of lymphocytes and plasma cells in the dilated vessels. 3. Mitosis and evident ameboid activity of plasma cells in both blood-vessels and tissues. In addition to the cells described by previous authors, he found large numbers of typical eosinophilic leucocytes in the interstitial exudation and in the blood-vessels in acute interstitial nephritis. In some places, in one case, these were the most numerous cells in the exudation. The eosinophilic leucocytes in the lesions of acute interstitial nephritis are for the most part brought to the part by the blood-vessels, and reach the interstitial tissue by emigration, but there is evidence—in one case—that they may be formed locally from plasma cells. The large phagocytic cells were not found.

52. **Cardiac Anomalies.**—Hektoen describes two cases of cardiac anomalies, one of defect of the septum between the pulmonary arteries and the aorta, and reviews similar reported cases, and one a peculiar small passage under the base of the anterior aortic valve, with regurgitation, hypertrophy and dilated arterial duct.

55. **Physiologic Cardiac Dilatation.**—Prince points out that the mitral valve is surrounded by circular muscular fibers, which he calls the mitral sphincter, though they are really a portion of the great cone of circular fibers that squeezes the blood out of the ventricle. The main point of his paper is its clinical significance shown under certain conditions, such as direct nervous excitement, etc. The mitral sphincter is forced to either dilate or prevented from sufficiently contracting, so as to produce the condition of mitral insufficiency and regurgitation. This may happen even when the dilatation is not sufficient to be detected by the usual methods. He points out the pathologic conditions in which this may occur, such as fatty degeneration and degenerative diseases generally, aortic stenosis, etc. He insists on the importance of recognition of this physiologic dilatation and physiologic valvular incompetency apart from pathologic varieties, and says we should question whether murmurs, dilatation, and irregularities thus occurring are in part or wholly physiologic, and, therefore, in part temporary or permanent, curable or incurable.

59. **Suprarenal Capsular Hemorrhage.**—Some degree of congestion of the suprarenal gland is held, by Mattei and Spencer, to be always present in the new-born. Hamill reports a case of a child who died shortly after birth, with pyresis in which there was found extensive hemorrhage into the right suprarenal gland and perirenal tissues, compressing the kidney. The only normal tissue found was within the infiltrated cortex. Two other cases are also reported, which are somewhat similar. In one there was a hemorrhage into the cortex and in the other the central sac containing a small amount of brownish, grumous material having the appearance of altered blood. In all three cases there was a papular eruption on the arms, shoulders and chest. The cases are discussed at length and the author seems to think that the causes of these occurrences in still-born children are probably prolonged and difficult labors, especially those requiring manipulation and delivery by the breech. In some infants dying within a few days after birth this factor may still be important in the etiology, but in the great majority some form of infection is responsible. This is the case in practically all instances where death occurs after the tenth day. The hemorrhage may be either unilateral or bilateral. In most of the cases which form the basis of his study it is bilateral. There are no symptoms which seem to be directly related to the lesion. When the hemorrhage is small, limited to one capsule, the symptoms would probably be slight. The immediate effect is now thought to be dependent on the degree of hemorrhage. In mild, non-infectious forms it is probably nil. He says, since these organs play an important part in the chemistry of the body, later consequences are likely to be serious, especially if the hemorrhage is at all extensive.

60. **Mitral Lesions in Children.**—Swift discusses the cases of anemic children with diseased mitral valves, as received in the hospitals, many of them coming as cases of chorea. Cases in private practice differ in no particular way. While ordinarily there is no evidence of dilatation or muscular degeneration, such an outcome is to be feared, and he asks whether the outlook for these cases is serious. The answer depends on the environment; the conditions being favorable, the outlook is good. We are not to expect the ordinary course of the inflammation on the endocardium in the adult, if the child is growing, as it must keep up a compensating hypertrophy. If general nutrition fails, the outlook is grave. The etiology of these cases is almost always, if not always, rheumatic. In the treatment we must overcome the cause, rheumatic poisoning, and improve the nutrition. If the heart is not doing its work well and the infection is active or the nervous system irritable, the best plan is to put the child to bed and keep it there. Prolonged quiet enables the heart muscles to regain their tone and reduces the nervous symptom. It may be wise also to administer some one of the salicylates, and he has found strontium salicylate the least irritating. This is important since the remedy must be kept up for a period of weeks or months. The formula is:

℞.	Sod. salicyl	ʒss	16	
	Tr. ferri chlor	ʒss	16	
	Ac. citric	gr. x		65
	Glycerin	℥iss	48	
	Ol. gaulth	gtt. viii		52
	Liq. ammon. citrat	ad ℥iv	128	

This is given after each meal, each dram containing 7½ gr. of sodium salicylate and 7½ m. of tincture of chlorid of iron. In some cases the original poisoning may have occurred through decayed teeth or inflamed tonsils, and these should be looked after. The great indication of care and treatment is to improve the nutrition. A few weeks of rest in bed and generous feeding will make the heart stronger, and decrease nervous irritability. Massage may be used if it is feasible. As the child recovers it should be gradually exercised. It is not wise, however, to push it. Two cases are reported.

70.—See abstract in The Journal, xxxvi, p. 527.

71.—See abstract in The Journal, xxxv, p. 1424.

73. **Blood-Vessels of the Kidney.**—Brödel describes the anatomy of the kidney, with special relations to the distribution of the blood-vessels, and elaborate illustrations. The principle landmarks are given for incision into the kidney.

avoiding the leading vessels. The description is only clearly intelligible by reference to the illustrations, for which the reader is referred to the paper itself. He suggests that the short incision be made into the lowermost posterior calyx, by means of a blunt dissection and through this incision the pelvis be explored. In the collapsed state this may be difficult, and a moderate distention of the pelvis with sterilized water or borax solution will facilitate the procedure. If this short incision does not prove satisfactory, the three middle calices should be carefully opened by means of an incision from within to the surface with a curved knife. The arrangement of the vessels in the kidney suggests the mattress suture as best adapted for approximating the two cut surfaces. Simple or interrupted sutures almost always tear the tissue and are unsatisfactory. The mattress suture should be placed at right angles, or nearly so, to the large vessels, and thus prevent any tearing of the kidney substance. If the bight of the suture be 1.5 to 2 cm., no strangulation will result. The pelvis is approximated with fine catgut sutures placed between the calices, and which involve only the fat, outer fibroid coat and the muscular layers. The second system of sutures should also be catgut, and should unite the region of the papillæ. They should be mattress sutures. The third system of catgut sutures should also be mattress sutures, and be placed parallel to the second, through the cortex near the bases of the pyramids. Occasionally this third system is superfluous. The capsule is then closed in the usual manner.

90. **Gunshot Wounds.**—Experience with gunshot wounds in the Philippines is given in detail by Robinson, who found that the Krag and Mauser bullets were alike in their effects, and the wounds they make generally aseptic. The Remington and revolver bullets, on the other hand, were generally infected. He gives a curious fact that the insurgents in the Philippines used the heads of matches for smokeless powder, producing still more decidedly infected wounds. The conclusions which he deduces are given as follows: 1. The modern gunshot wound is generally aseptic, and should be treated on this supposition. 2. Asepsis is due chiefly to the character of the bullet, and early application of first-aid dressing, and in minor degree to the velocity of the projectile. 3. Primary hemorrhage from modern gunshot wounds is exceedingly rare, the blood-vessels being displaced rather than cut by the rapidly moving projectile. 4. The "explosive effect" of the modern bullet is much less common than recent military literature would indicate. This peculiar destructive effect is produced by the character of the tissue struck, as well as by the great velocity of the bullet. 5. Gunshot wounds of the chest are rarely infected. Simple antiseptic treatment, with aspiration of the pleura in cases with severe hemorrhage is all that is necessary. 6. Gunshot wounds of the knee-joint are usually aseptic, but, if infected, demand immediate amputation to save life. 7. Excision of the elbow is always a justifiable operation in severe shattering or infection of that joint. Resection of bones of other joints is rarely necessary, erasion or amputation being preferable. 8. Injuries of nerves from gunshot wounds can often be benefited by operative interference or resection. 9. In modern military surgery, abdominal section for gunshot wound is not justifiable; the patient's best chance of recovery lies in conservative treatment without operation.

91. **Sarcoma of Uterus.**—From a study of 118 cases of sarcoma of the uterus, collected from the literature, Knott notices the importance of the early employment of the microscope. He concludes that the only treatment that accomplishes anything is the early and complete removal of the uterus and its appendages. The prognosis of sarcoma is not as favorable as in carcinoma of the uterus. In 20 of the 118 cases the result of the operation was not stated; in 12 of the remainder no rational operation was performed, leaving 86 cases of hysterectomy. Of this number 31 were said to have recovered, but in many of them the results were not followed for a sufficiently long time. The real mortality would probably be still higher.

92. **Multilocular Renal Cyst.**—After remarks on the rapidity of the disease, its occasional lack of symptoms and the diagnosis, Beck reports a case of which he gives an illustration. Operation was performed and the kidney removed, the patient succumbing to intestinal nephritis eleven days later. He states that it has become doubtful to him whether it will ever be justifiable to remove a cystic kidney, even when the other appears to be normal. The case described by him very strongly suggests that puncture followed by an injection of a drop of saturated solution of iodoform and ether should be tried on the small cysts, while, in the large ones, the peripheral walls should be excised. Very large cysts might even be totally exsected, the wound of the kidney being united by suture of formalin catgut. This can be done by the lumbar route, while the transperitoneal may be resorted to only in obscure cases or where the tumor is of very large size.

94.—See abstract in The Journal, xxxv, p. 1499.

96.—Ibid., xxxv, p. 323.

104. **Ear Disease in its Relationship to the Cranial Cavity.**—Stein insists on the importance of middle ear disease in its relation to the brain, and points out the methods of entrance of infection into the interior of the cranium, and the possibility of phlebitis, sinus thrombosis, abscesses, etc., the symptoms attending them, their diagnosis and prognosis.

106. **Nasal Depressions.**—Goodale reports a case of depression from septal abscess, corrected by elevating a portion of the triangular cartilage and one of correction of deformity from an old depressed fracture in the nasal bone, by subcutaneous implantation by a septal spur.

111.—See abstract in The Journal, xxxv, p. 1172.

115.—Ibid., p. 448.

116.—Ibid.

118. **The Bones in Leprosy and Syphilis.**—Ashmead argues that leprosy is not an American disease, but was introduced from Asia, and that in the early or middle ages leprosy and syphilis were largely confused. Leprosy attacks the bones of the digits, while syphilis may affect almost any bony region. Syphilis undoubtedly pre-existed in both continents.

119.—See abstract in The Journal of January 19, p. 205.

122. **Enuresis.**—Four cases of enuresis are reported in children from 7 to 12 years of age, in whom the usual remedies failed. Examination showed more or less ocular defect, producing eye-strain. Glasses were prescribed and the correction made with the result of relieving the symptom. Frame has not found much literature on this cause of enuresis, though Gould reported several cases cured by correcting the refractive errors. During his twenty years' practice, he has seen a number of resistant cases which he is now inclined to think may have been similar to those reported. He believes a certain number depend entirely on ocular strain, and, whenever medication fails, we should refer the case to an oculist for examination.

133. **Rectal Obstipation.**—Cooke reviews the causes of rectal obstruction, describing the Houston valves especially, and noticing their pathologic condition in which they may be the cause of inconvenience and serious symptoms. Other conditions that may produce rectal obstipation are spasm of the sphincter, hyperplasia and contraction of the levator ani, but the rectal valves particularly form the subject of his article. He says that the operation to relieve this condition, though slight, requiring neither local nor general anesthesia, nor long

confinement to bed, is nevertheless one of the most delicate in surgery. The operation in these cases is almost imperative, since the trouble is seldom recognized in its early stages. It consists simply in incising the valves' free margin down to their muscular coat, but for its proper and safe performance a very thorough knowledge of the anatomy of the parts is required.

134. **Antitoxin.**—Happel details four cases of diphtheria treated with antitoxin, with the intention of impressing on the profession the importance of using this remedy. He agrees with those who hold that there is no maximum dose of antitoxin. Generally speaking, it should never be less than 1000 or 1500 units in any case, and not less than 3000 units in any case of laryngeal diphtheria of malignant type, or in those of a longer standing than twenty-four hours.

135. **Rectal Disorders.**—The first of the rectal troubles noticed by Cox is constipation. He has not found divulsion of the external sphincter of benefit, but he has had one case cured by valvotomy, which he notices in detail because such operations are not usually performed by the general practitioner. The other rectal disorders mentioned are rectal ulcer, which he treats with dilatation of the rectum and tamponing, cleansing and scarifying the ulcer and using a 5 to 10 per cent. solution of nitrate of silver. Hemorrhoids are also mentioned; he treats them by ligation and incision of the tumor above the ligature.

146. **Rhatany.**—Howard calls attention to the use of rhatany as an astringent in cases of bladder trouble, giving his own case as an instance of its value. He got the idea of using it from reading Watson's Practice, but he has found that it is hardly at all in use by the profession at the present day. The paper is written for the purpose of calling the attention of the profession to its value.

FOREIGN.

British Medical Journal, February 9.

Ringworm Infection in Man and Animals. J. L. Bunch. Ringworm is generally considered to be due to two classes of fungus, microsporon and trichophyton, which can be distinguished to a certain extent clinically and microscopically, but still better in cultures. There is a less common form due to a fungus, which cultures give a faviform growth, but the lesions of this are either circinate or well-marked kerion. The trichophyton class includes two forms, the ectothrix, both large and small spored, and the endothrix, while an intermediate variety may be distinguished microscopically, in which the fungus lies both within and without the hairs. The etiology of these different forms is always obscure and Bunch relates the cases he has investigated of the disease contracted from the lower animals. Inasmuch as ringworm cultures can be inoculated into animals and vice versa, the possibility of the animals having received the infection from the human species in his case is excluded by the dates of the first symptoms. The first two cases were those in which the ectothrix eruptions were found and traced back to a horse. The third case was that of a boy with kerion of the scalp, the infection of which was traced to a terrier. The fourth case occurred in a child only four weeks old and a cat in the house was troubled with a bare patch, cultures from which gave a more luxuriant growth than cultures from the child, but their identity is not doubted. Still other cases are reported from cats, one of these being endothrix. Other animals from which the condition seemed to be derived were pet canaries and calves. These cases are the results of a very considerable study lasting over a period of three years. The number of such cases having such an origin must always be a very small percentage of the whole, as the infection has a much better chance to spread in the same species.

Finsen's Light Treatment of Lupus and Rodent Ulcer. Malcolm Morris and S. Ernest Dore.—The authors report their experience with the light treatment of lupus and rodent ulcer, giving first some details of the technique. A current of about 75 amperes and 60 volts is usually sufficient. The lenses must be in good order, clean and bright, and the water free from floating particles. The area treated is kept well within the focus of the light, but a smaller focus, if it can be borne, gives better results. The rays should fall perpendicularly on the compressing glass, and the compressors are kept in place by elastics. Resulting reaction varies somewhat with the idiosyncrasy of the patient. The time of its appearance varies from five to six to twenty-four hours. It is usually slight at first, becoming more marked later, and the duration of the sore, from primary hyperemia to complete healing, is from ten days to a fortnight. When situated over loose tissue, for example the eye, there is often great swelling of the neighboring parts, so that the eye may be nearly closed. Lupus vulgaris is the disease most amenable; sometimes one application is sufficient to cause the disappearance of a small isolated superficial nodule. Generally in extensive cases a single spot is treated daily, and the parts first treated are sufficiently healed in a few days to allow of their being treated again. If it is only a small area the application may be continued as long as possible, until soreness of the part necessitates cessation for a few days, when it is again continued. In extensive cases the treatment may have to be continued over a year and pyrogallic acid ointment, where there is great thickness of the skin, quickens the action. In rodent ulcer the healing often follows quickly after the application. In lupus erythematosus the effects have been marked, though not so certain as in lupus vulgaris. Constitutional effects are practically nil. The effects on the eye have been harmless, though the lids themselves have been involved. In one case, where the skin of the nose was treated, improvement took place in the mucous membrane and sense of smell. In preparing the patient, the crusts are removed with forceps, the area is then bathed with boric lotion, and, if there is any grease on the spot, with ether. The skin is then marked with a blue pencil to localize the application. After treatment the compressors are cleaned with spirit and carbolic acid. The disease surface treated is dressed if necessary, with a simple zinc lanolin ointment, or a paste with zinc, vaselin and starch, and a little boric acid. The unfavorable conditions are those which hinder the penetration of light, such as scarring, pigmentation, great vascularity, great depth below the surface of the disease, and the situation of the disease in a position to embarrass the application or make it inaccessible. In very extensive disease the condition is unfavorable, both on account of the long duration of treatment and the possibility of its spreading in one direction while another is being treated. Cases are favorable when the disease is limited, not spreading, and has undergone no previous treatment. The advantages of the method are reliability, painlessness, excellent cosmetic results, less liability to relapse, and avoidance of surgery. The disadvantages are the small area treated at a time, long time required and the expense. The rest of the paper is taken up with a report of cases.

Surgical Treatment of Migraine. Walter Whitehead.—The author recommends the use of the seton for the treatment of migraine, a method which he has employed for the last twenty-five years with the greatest success. The seton is introduced through the skin at the back of the neck, and instructions are given to move the tape from side to side each day. This should be worn interruptedly for three months at least, in the first instance, and if the symptoms recur, a second seton ought to be introduced.

The Lancet, February 9.

Gastric Hemorrhage and its Surgical Treatment. A. W. Mayo Robson.—The conclusions reached by Robson, concerning the treatment of gastric ulcer, are: 1. All cases of acute uncomplicated gastric ulcer should be submitted to thorough medical treatment in the shape of long-continued rest and attention to the diet, the patients not being allowed to get up or resume solid food until at least a fortnight after all disappearance of the pain. 2. Where the ulceration persists and proves intractable to medical treatment, or where relapses occur, gastro-enterostomy should be performed so as to secure physiologic rest and relieve the hyperacidity of the gastric juice nearly always found in such cases. 3. Perforation demands immediate surgical treatment. 4. The complications of disabling adhesions around the stomach and pylorus, pyloric contraction, and hour-glass contraction due to chronic ulcers leading to pain, dilatation, loss of flesh, and general impairment of health, now often treated as chronic indigestion, should be treated surgically. 5. In recurring or so-called chronic hematemesis from gastric ulcer surgical treatment is decidedly called for. In acute hematemesis, further accuracy in diagnosis as to the size of the bleeding vessels is urgently needed; and the co-operation of the physician and surgeon is advisable in all cases of hematemesis, so that if relief be not obtained by medical treatment, surgical means may be adopted if the bleeding is believed to occur from a large vessel; but seeing that capillary hemorrhage is capable of relief by medical means alone, medical should always precede surgical treatment.

A Plea for More Careful Study of the Symptoms of Perforation in Typhoid Fever with a View to Early Operation. William Osler.—The author pleads for an early diagnosis of symptoms in perforation in typhoid, points out the diminishing mortality of late years and the possibility of saving many patients if the condition is recognized before peritonitis has fully set in. He lays down a schedule of symptoms to be observed: the character of the pain, locality, the distention or otherwise of the abdomen, limitations of respiratory movement, percussion and auscultation signs, the rectal and genito-urinary symptoms, facies of the patient, changes in the pulse, temperature, hiccough, vomiting and leukopenia and condition of red blood-corpuscles and the hemoglobin. These are all indicated, with many other more detailed symptoms. The *most constant symptom is sudden pain, increasing in intensity* and recurring in paroxysms, and this with increase of pulse rate, distention of abdomen with great tenderness on pressure and rising leucocytosis make the diagnosis probable. A surgical colleague should be called early to share the responsibility, and in doubtful cases the patients should be given the benefit of the doubt and operation be urged.

Observations Based on the Probable Mode of Formation of Urinary Stone, Relative to its Recurrence and Prevention. Reginald Harrison.—The great frequency of recurrence of vesical calculus with the modern operation of litholapaxy has led Harrison to call attention to the treatment of the bladder following the operation and the preventative treatment based upon the mode that it is held urinary calculi are formed. He has for some time regarded all cases operated on for stone as suspicious until a sufficient interval has elapsed to free these from this imputation. The patient should be watched, and, if the condition of the urine becomes abnormal in any way, the bladder should be carefully attended to and washed out as for exploration, so as to remove any small forming concretions before they get large. In some cases where the bladder is sacculated, and to make doubly sure, it is well to wash out with the evacuation catheter and aspirator, as after litholapaxy. The causation of stone is connected with some as yet imperfectly understood chemical process, and Rainey's experiments as to artificial production of these formations are noticed. We have probably paid too much attention to the possible causes arising out of cases of special characteristic ingredients in the urine, instead of considering other conditions capable of bringing this about by consolidation of what is natural in the urine. He thinks that an increase in the quantity of urinary mucus may provide a basis for stone formation and an uncleanly condition of the urine may be a favoring condition. Some years ago he called attention to a soluble and digestible salt of boric acid, borocitrate of magnesia, which has a valuable action in sterilizing the urine. Drugs such as the benzoates of sodium and ammonia, hyposulphite of sodium, etc., are also exceedingly useful. After noticing several cases he calls attention to the general principles, which should not be forgotten, of noticing abnormalities, such as excess of urates, uric acid, and oxalates, but for the most part his contentions are based on proportions which may be normal. In the operation for removing stone from the bladder, two things should be looked after: 1. After every crushing operation it should be insured that every particle of debris is removed. A bladder obstructed by enlarged prostate is *apt to resemble the section of* a coarse bath sponge rather than the outside of a teacup, and the chances for *enlargement of particles are greatly increased.* 2. Care should be exercised in any kind of operations to avoid *introducing rough scar tissue into the bladder. Phosphatic concretions on rough uneven surfaces are likely to be formed.*

Archives Generales de Medecine (Paris), January.

Mercurial Injections in Hemorrhagic Diseases. A. Lusignoli.—This communication asserts that hemorrhagic affections, such as scorbutus, purpura and Werlhoff's disease, are produced by a special micro-organism whose products pass into the blood. These various diseases are all of the same nature and differ merely in intensity. The writer announces that they can be cured by intravenous injections of 1 to 4 mg. a day of mercuric chlorid, according to Baccelli's method. He describes five cases cured in a week by this treatment.

Circling for Fractures of the Patella. P. A. Cassedebat.—Extremely favorable results were obtained in a severe case of fracture of the patella, which would inevitably have left a deformity if treated by any other method than circling. Berger was the first to call attention to the advantages of passing a silver wire around the fractured patella, thus holding the fragments together in a loop, instead of suturing them together. Cassedebat is so impressed with the value of the method that he advocates it as a routine measure, instead of reserving it for the gravest cases.

Progres Med. (Paris), January 26 and February 2.

Mountain and Balloon Sickness. E. Guglielminetti.—The project to build a railroad to the summit of the Jungfrau has given a new impetus to the study of the effects of rarefied air on the system. The writer of this profusely illustrated article spent two weeks on the summit of Mont Blanc, with a number of workmen, and experienced an acute attack of mountain sickness. His companion, Dr. Jacottet, of Neuchatel, died after five days of suffering, and several of the workmen were affected. None was relieved at any time by inhalations of oxygen. He is convinced that mountain sickness is essentially the result of mechanical disturbances in the circulation; the diminished atmospheric pressure leads to the accumulation of blood in the peripheral vessels which are gorged, while the arteries are depleted, with consequent anemia in the brain. The pulmonary vessels swell, the blood stagnates in them and the cavities of the right heart become dilated. Chemical disturbances—the anoxyhemia—have a subordinate rôle. Treatment should be addressed to the circulation, with remedies that act on the vessels and on the heart, such as caffein, strychnin and subcutaneous injections of salt solution. [Aron has recently published an experimental study of the effects of rarefied air. He found the inhalation of oxygen effective in banishing the cyanosis and disturbances experienced in the pneumatic chamber, but he noted that the oxygen, while materially relieving, did not restore the respiration to normal, confirming the assumption that beside the chemical, important physical factors are also at work in mountain sickness.—Zeitschr. f. Klin. Med., xii. Ed.]

Revue de Medecine (Paris), January.

Nephritis of Pregnancy. E. Gaucher.—The nephritis of pregnancy is of an autotoxic nature and, consequently, *epithelial at first.* If the cause persists—either prolonged intoxication or repeated invasion from successive pregnancies—the lesion becomes interstitial and assumes the anatomico-clinical characteristics of chronic, mixed nephritis, predominantly interstitial. Whatever the nature of the poison, whether mineral, vegetable or animal, all varieties of toxic nephritis have the same evolution.

Re-education of the Movements of the Heart. F. Lagrange.—A series of pulse-tracings are given to demonstrate the efficacy of systematically applied exercises in regulating anomalies in form, amplitude, frequency or rhythm of the arterial pulse. Thoracic aspiration is an important indirect aid in drawing the blood in the direction in which it is impelled by the systole. The lung can be made to co-operate in forcing the blood along. Massage is another means of promoting the circulation in case of asystolia. Deep massage of the abdomen empties the veins, especially the portal vessels, and the amount of blood in the arteries is proportionately increased, augmenting their resistance and thus regulating the action of the heart in turn. The wild pulse observed while the heart is comparatively empty approximates to normal as the flow through the heart is increased. On the other hand, in arteriosclerosis, the indications are the reverse, the arterial tension requires to be reduced instead of increased. Massage is also the remedy in this case, but not deep, mechanical, as before, but superficial. The aim is to induce vaso-dilating reflexes by lively, superficial physiologic friction, slapping and pinching. When this is applied lightly to the four members, avoiding the trunk, the arterial tension is reduced, the blood drawn to the periphery and the functioning of the heart favorably modified.

Tendon Reflexes in Typhoid Fever. P. Remlinger.—The tendon reflexes were exaggerated in 32 per cent. of the cases of typhoid fever examined by Remlinger, diminished in 17, abolished in 29, and unmodified in 22 per cent. His impression is that the exaggeration occurs in the grave, ataxic and ataxo-adynamic cases.

Traumatic Diabetes with Throat Symptoms. P. Vergely.—Almost every one of the complications and nervous symptoms of ordinary diabetes are seen in the traumatic variety. The glycosuria may not appear for a long interval after the trauma, which probably merely rouses some latent predisposition in the organism. Any unusual, strange, nervous phenomenon that can not be traced to a neurosis or organic lesion, should suggest the possibility of a disturbance in nutrition, and examination of the urine will reveal its significance. In the case described, dyspnea, simulating angina pectoris, was the first and, for months, the only symptom of the traumatic diabetes.

Allg. Med. Cent. Ztg. (Vienna), January 23.

Colloid Silver a Specific Against Sepsis. P. Viett.—Credé's colloid silver is not toxic, and Viett uses it in larger quantities than is generally recommended. He considers it a specific against sepsis. It is especially valuable in country practice and completely fulfils Credé's claims for it in this respect. In puerperal sepsis, appendicitis, etc., Viett rubs the silver salve—unguentum Credé—on regions remote from the morbid process, in some cases using as much as 12 gm. in nine hours for an adult, 8 gm. in eight hours for a child of 7, and 2 gm. a day for an infant of 3 months.

Beitraege z. Geb. u. Gyn. (Leipsic), III, 1 to 3.

Experimental Tests of Various Methods of Resuscitating the Newly Born. B. S. Schultze.—Spirometer tracings are given showing the superior efficacy of Schultze's swinging method over all others for inducing artificial respiration in new-born infants. Tests on 29 cadavers of still-born infants showed that swinging freed the lungs from mucus and rendered energetic inspirations possible. Sylvester's method was the only one to be compared with it.

Etiology of Malignant Tumors. A. Hegar.—The cell of a malignant tumor is an injured tissue cell, whose differentiation has been impaired. The injury may have occurred in embryonal or extrauterine life or possibly in the germ-plasma. Injurious factors are numerous, among them the products of bacterial metabolism have an important place. The tissue cell possesses the inherent faculty of growth, which is necessary to form a malignant tumor. A stimulus to proliferation is, however, required to set this faculty in action. The injurious factor and the stimulus to proliferate, in all probability, frequently originate from the same source, the toxins evolved by micro-organisms. In the prophylaxis of malignant tumors everything tending to the normal regeneration of the cells should be favored, especially by diet suitable to the individual, the occupation and the age. Infections of all kinds should be scrupulously avoided, gonorrhea and syphilis in particular. Local irritation of the tissues and stagnation of excreta should also be prevented. Local venous hyperemia should be relieved and abolished, and all defects in the epithelium prevented by a mild astringent or zinc or boricized salve.

Remote Results of Prolapsus Operations. O. V. Herff.—Surgical methods of treating prolapsus uteri are all unsatisfactory, as they can not restore the missing tonicity to the tissues. This can be accomplished only by therapeutic gymnastics and the avoidance of violent efforts on the part of the abdominal muscles. Herff reviews the remote results of 283 operations for prolapse. Complete working capacity was restored in 37.2 per cent. after simple colporrhaphy or perineorrhaphy; after complicated intervention in 50 per cent.; after vaginal or vesical fixation in 41.8 per cent.; after ventral fixation in 53.8 per cent., and after hysterectomy in 55.1 per cent. Freund's operation was performed seven times and the threads cut through in every case with only partial restoration of the working capacity; Mueller's operation was done in two cases, with complete restoration in one.

New Method of Shortening the Cervix. H. Fuchs.—The advantage of the operation described is that the vaginal portion is retained intact, with no cicatricial ring. The cervix is resected above, the lips of the os uteri detached and mobilized, but the connection with the vagina left undisturbed. Nine patients have been thus operated on at Kiel with eminently satisfactory results, and with no interference with pregnancy.

Beitraege z. Klin. Chirurgie (Tuebingen), December.

Experiences with Beck's Operation for Hypospadias. G. Marwedel.—Beck's method of forward dislocation of the urethra in the treatment of hypospadias was applied by Marwedel in seven cases, the children ranging between 1 and 9 years of age. In 3, the operation was completely successful; in 2, a slight secondary operation was necessary. In one of the others a large hematoma formed, requiring the Thiersch operation. In this and another case erections interfered with the healing. A permanent catheter was found indispensable in nearly every case, contrary to Beck's experience. No necrosis of the urethra was observed, but in two cases a small urinary fistula persisted at the lower angle of the wound, although the urethra had not been injured and the wound had healed by first intention.

Appendicitis in Hernial Sac. F. Tacke.—A small lump was noted for three months in the right inguinal region. It suddenly increased in size and became extremely painful, the swelling involving the entire inguinal region and scrotum, with fever, vomiting, depression and diarrhea. The hernial sac contained a portion of the intact cecum and the suppurating appendix, perforated at the tip. Tacke has collected twenty-eight somewhat similar cases in the literature.

Rectal Exploration and Incision in Appendicitis. A. Langemak.—The advantages and necessity of rectal exploration in all cases of suspected appendicitis are announced by Langemak. He describes a number of cases in which the surgical intervention was by the rectal route, with the most satisfactory results, including a case of hemorrhage from erosion. Not a trace of ascending infection was observed in any case.

Irreducible Luxation of the Shoulder. E. Schoch.—One personal case is reported and fifty-four in the literature are reviewed. The results obtained by the various methods of treatment emphasize the fact that arthrotomy is the standard procedure in all recent cases. In older cases arthrotomy should be tried first, but if the head is found much injured, resection should be done. In his personal case, a young farmer, normal function for any kind of work was restored to the joint.

Esophagoscopy for Foreign Bodies. V. V. Hacker.—During the last eight years Hacker has had occasion to remove foreign bodies from the esophagus twenty-seven times. By the aid of esophagoscopy all were located and removed without injury to the patient, only one requiring gastrostomy. He explores with a sound tipped with metal or ivory, which grates when brought in contact with the foreign body. During this same period fourteen esophagotomies were done at Gussenbauer's clinic at Vienna for the same indications.

Operative Treatment of Basedow's Disease. B. Witmer.—The 23 cases of Basedow's disease operated on by Kroenlein are analyzed and followed to date in this communication. In 18 the operation was successful; in 2 it did not affect the course of the disease; 2 died, and the fate of 1 is unknown. The mortality was thus 8.6 per cent. Mikulicz reports 4.8; Czerny, 1 in 4; Kocher, 3 in 34, while all of Kummel's 20 patients were restored to their working capacity. In Rehn's collective statistics the mortality is given at 13.6 per cent.

Gazetta Degli Osp. (Milan), January 3.

Differentiating Receptacle for Gonorrheal Urine. I. Castracane.—The patient urinates directly into a flaring tube 2 cm. in diameter, holding about 300 c.c. It is bent into the shape of three Us in a row, thus automatically separating the urine into three portions, each of the same height and volume, easily inspected through the glass, which is graduated. Tests with colored fluids showed that the contents of the first loop are forced into the second and on into the third loop without blending with the following portions of fluid, although it is poured into the receptacle in a continuous stream.

Anales Del Circ. Med. Arg. (Buenos Ayres), December.

Serotherapy for Anthrax in Man. F. Dasso.—The anti-anthrax serum prepared by Mendez is much more powerful than Sclavo's or Sobernheim's. Dasso reports 130 cases treated with it, with the constant result of falling temperature, disappearance of the edema, general improvement and resolution of the ganglionary infarct. Nine of the patients died, all but two from secondary infection. The remainder of the cases all testify to the efficiency and specific character of Mendez's serum. The dose is 10 c.c., injected subcutaneously.

Antitoxin for Mosquito Bites. Voges.—Naphthalan is the substance which Voges calls an antitoxin for mosquito bites. He states that its action on the poison from the bite is as effective and specific as that of an antitoxin on the bacterial toxin. Voges is at the head of the National Department of Hygiene of the Argentine Republic.

Klinitchesky Journal (Moscow), December.

Experimental Embolism of the Coronary Arteries. A. Foxt.—The functional and anatomic alterations caused by embolism of the coronary arteries have been studied by Foxt on large dogs. He introduced minute seeds into the coronary arteries through the aorta. When the main stem of the anterior branch of the left coronary artery was completely occluded, death ensued in eight minutes from arrest of the heart, but when smaller ramifications were involved, survival for several days was possible. The obstructions in the finer branches disturbed the functioning of the neuromuscular apparatus of the heart and interfered with the establishment of collateral circulation. Marked arrhythmia and diminished systolic elevation were produced in every case and also pronounced mechanical dilatation of the cavities of the heart, especially the left ventricle, but these symptoms passed away as collateral circulation was established. There was always extravasation of blood around the occluded points and patches of anemia in the myocardium. Comparison of the results of this experimental research, and clinical experience of thrombosis and sclerosis of the coronary arteries, demonstrates that the chief cause of the disturbances in each case is the general, persisting anemia in the myocardium. The entire syndrome, subjective and objective, is the consequence of the intense disturbance of the tonicity of the muscle, resulting from this anemia, and the disturbed tonicity entails various degrees of mechanical dilatation of the different cavities of the heart. The collateral circulation that may finally be established is evidently inadequate for the maintenance, although it may sometimes prove sufficient for the regulating function of the heart under ordinary circumstances. Foxt's experiments also demonstrate a certain periodicity in the symptoms observed, which explains the fact that alterations in the coronary arteries are sometimes found at autopsies when no symptoms had been observed during life, owing to the remission of the symptoms at the time of examination.

Change of Address.

N. M. Black, 1801 Grand Ave., to 177 14th St., Milwaukee, Wis.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Feb. 7 to 13, 1901, inclusive.

George W. Adair, *major and surgeon, U. S. A., member of a* board at Fort Sheridan, Ill., to examine enlisted men for promotion.

Max A. Becher, acting asst.-surgeon, from Los Angeles to San Francisco, Cal., to accompany troops to Manila, P. I., and for subsequent assignment in the Division of the Philippines.

William H. Corbusier, major and surgeon, U. S. A., member of board at Governor's Island, N. Y., to examine enlisted men recommended for commissions.

William D. Crosby, captain and asst.-surgeon, U. S. A., as Corbusier above.

Guy L. Edie, major and surgeon, Vols., relieved from further duty in the Division of the Philippines and assigned to temporary duty in the Department of California.

Louis T. Hess, lieutenant and asst.-surgeon, U. S. A., member of a board at San Francisco, Cal., to examine enlisted men for promotion.

John Van R. Hoff, major and surgeon, U. S. A., member of a retiring board in Washington, D. C.

John S. Marshall, dental surgeon, U. S. A., from Chicago, Ill., to Washington, D. C., to report to the Surgeon-General for instructions.

James C. Merrill, major and surgeon, U. S. A., member of a retiring board in Washington, D. C.

Robert W. Morgan, dental surgeon, U. S. A., from Lynchburg, Va., to report at Washington, D. C., to the Surgeon-General for instructions.

Edward R. Morris, captain and asst.-surgeon, U. S. A., in addition to his present duties, to act as examiner of recruits at the city of Detroit, Mich.

Edward L. Munson, captain and asst.-surgeon, U. S. A., leave of absence granted on account of sickness.

Robert T. Oliver, dental surgeon, U. S. A., from Indianapolis, Ind., to Washington, D. C., to report to the Surgeon-General for instructions.

William E. Purviance, captain and asst.-surgeon, U. S. A., member of a board at San Francisco, Cal., to examine enlisted men for promotion.

Charles Richard, major and surgeon, U. S. A., *member of a* board at Fort Leavenworth, Kan., to examine enlisted men for promotion.

Samuel S. Turner, acting asst.-surgeon, member of a board at Fort Sheridan, Ill., to examine enlisted men for promotion.

Robert Winn, acting asst.-surgeon, member of board at Fort Leavenworth, Kan., to examine enlisted men for promotion.

In addition to the above the following named medical officers were appointed to membership on boards to be convened March 1, 1901, at the stations designated, for the mental and physical examination of such candidates for the Military Academy as may be authorized to appear before them: Major John M. Banister, surgeon, U. S. A., and Lieut. Franklin M. Kemp, asst.-surgeon, U. S. A., at West Point, N. Y.; Acting Asst.-Surgeon John S. Fogg, at Fort McHenry, Md.; Maj. William O. Owen, surgeon, U. S. A., at Fort Thomas, Ky.; Capt. Harry M. Hallock, asst.-surgeon, U. S. A., at Fort McPherson, Ga.; Maj. Aaron H. Appel, surgeon, U. S. A., at Jackson Barracks, La.; Maj. Charles B. Byrne, surgeon, U. S. A., at Fort Sam [illegible] Henry I. Raymond, asst.-surgeon, U. S. A. [illegible] Maj. Marshall W. Wood, surgeon, U. S. A. [illegible] Mo.; Maj. Charles Richard, surgeon, U. S. A., at Fort Leavenworth, Kan.; Capt. Alfred E. Bradley, asst.-surgeon, U. S. A., at Fort Snelling, Minn.; Lieut.-Col. Henry Lippincott, deputy surgeon-general, U. S. A., at Fort Logan, Colo.; Acting Asst.-Surgeon Carle E. Bentley, at Fort Logan H. Roots, Ark.; Maj. John D. Hall, surgeon, U. S. A., at the Presidio of San Francisco, Cal., and Maj. Louis S. Tesson, surgeon, U. S. A., at Vancouver Barracks, Wash.

Special Order, No. 218, Headquarters Division of the Philippines, Manila, P. I., Dec. 21, 1900, reads as follows: Upon recommendation of the chief surgeon of the Division, the following named

Weakness of the heart is the complication most to be feared. In the fatal cases the operation is not in itself the cause of death, but it merely gives the slight impetus required. The operation was limited to resection of the struma in 19 cases with 1 death; enucleation, in 3, and ligature of the artery in 2 with one death. Generally speaking, Witmer concludes, the treatment of Basedow's disease is internal. If no improvement is manifest in spite of internal measures, surgical intervention should be resorted to. Symptoms of stenosis indicate operation.

Therapeutische Monatshefte (Berlin), December.

Prevention of Tuberculosis in Children. E. Feer.—Absolute cleanliness, sunshine, fresh air and exercise out of doors are the factors in the prevention of tuberculosis as well for children as for adults. Among the minor points Feer mentions that the bedding in hotels, etc., should be covered with a washable sheet to prevent infection from the blankets, and that a sheet should be spread on the floor for young children to play on, never putting them down on a carpet, especially in a hotel. If possible, the child should be confined to the sheet with a light, folding fence around it. The teeth should be carefully supervised, as tubercular infection may occur through a cavity at any age. Precautions should be multiplied in case of children with a tendency to glandular affections.

Atmocausis and Zestocausis. W. Stoeckel.—Treatment with steam is the only certain means at our command for controlling menstrual and climacteric hemorrhage, according to Stoeckel. It can be depended on in all cases without complications such as myomata, polypi, relics of abortion or much endometritic alterations. It is especially prompt and reliable in violent climacteric hemorrhages, and far superior to the curette for this purpose.

Zeitschrift f. Geb. u. Gyn. (Stuttgart), XLIV, 1 and 2.

Incipient Chancroid of the Portio. O. V. Franque.—The normal anatomic conditions of the uterus completely justify supravaginal amputation in case of commencing chancroid of the portio as a sufficient and satisfactory operation. Franque has not been able to find a single case in which the lymph-glands were involved. Even in the progressive and extreme cases the involvement of the body of the uterus is the rare exception. By the arrangement of the lymph-glands in the region, dissemination in this direction is against the current.

Severe Paralysis of the Stomach and Intestine, Especially After Operations. O. V. Herff.—Two personal observations are added to the 32 cases on record of acute paresis or paralysis of the stomach, inducing extreme dilatation and mechanical occlusion of the adjoining portion of the duodenum. All but 5 were fatal; 12 occurred consecutive to various operations, with nothing in common but the chloroform narcosis. The primary cause is probably injury of the nervous apparatus of the stomach from trauma of the spinal cord in some cases, in others from pathologic distention of the stomach from abnormal fermentations, and in others from the toxic action of the chloroform or from autointoxication. For a certain number of the cases no plausible explanation can be advanced. A predisposition existed in all of the patients, from preceding emaciation, debility or a chronic gastric affection. Many were convalescing from various diseases. In the majority of cases the paralysis occurred with no appreciable direct cause, the patients being still under surveillance in the hospital. The age in 70 per cent. was between 17 and 30. Persistent vomiting after chloroform should suggest the possibility of acute dilatation of the stomach from paralysis. When suspected, the stomach should be promptly and systematically rinsed and all food per os prohibited. The rapidly-failing strength should be sustained with rectal feeding, wine and faradization of the stomach. Rectal injections of 1 to 1.5 liters of salt solution will counteract the excessive thirst. The knee-elbow position or ventral decubitus may assist the treatment. The vomiting is the chief symptom, accompanied by violent pain and tympanism of the stomach, intense thirst, absence of gastric peristalsis and indications of cardiac insufficiency with normal or subnormal temperature. In 3 of the 5 patients who recovered chronic atony of the stomach persisted for years. Two were unmistakably saved by prompt rinsing of the stomach with chloroform water. Death is usually due to inanition or lack of water.

Zeitschrift f. Hyg. u. Inf. (Leipsic), XXXV, 1.

Survival of Micro-organisms in Spray. F. Kirstein.—Forty-two pages are devoted to the description of the tests at the Giessen Institute of Hygiene, which showed that when bacteria without spores, disseminated in fine spray, are exposed to the action of air and light they survive but a comparatively short time.

Zeitschrift f. Klin. Med. (Berlin), XXI and XXII, 1.

Gelatin Treatment of Aneurysms. J. Sorgo.—Six cases are described in which aneurysms were treated by injections of a solution of gelatin. Forty-two aneurysms treated with gelatin are also recorded in literature. Analyzing these 48 cases, Sorgo finds that in 18 the aneurysm was sacculated, and organized coagula formed in 13. In the 16 non-sacculated cases no clot-formation occurred. In one of his personal cases the ascending aorta was the seat of a diffuse aneurysm, and the innominate of a sacculated aneurysm. The latter was filled with clots, while there was no trace of them in the former. Prolonged repose and suitable diet, especially milk, create conditions favorable to the obliteration of a sacculated aneurysm, and consequently he thinks we are not justified in ascribing the obliteration of the sac to the influence of the gelatin. In a number of cases of hemorrhage from various sources hemostasis occurred after local or subcutaneous injections of gelatin. It is impossible to assert, however, that in any case the gelatin was the direct cause of the hemostasis or clot-formation, because the same effect might have followed the restricted diet and repose, and because in many cases there was no hemostatic action; because the result may have been merely a coincidence, and because no experimental proof of the coagulating action of gelatin has been offered to date. The experiences in the 48 cases show that injections of gelatin are harmless even in quite concentrated solutions. The pains sometimes caused by them are favorable on the whole, as they compel repose. Experience has also demonstrated that kidney affections are no contraindication to the administration of gelatin by the mouth. The question is still undecided in respect to subcutaneous injections.

Connection Between Diabetes and Tabes. W. Croner.—Diabetes may appear on a foundation of arteriosclerosis, and the latter is due to syphilitic infection in many cases. Affections of the pancreas with consecutive diabetes may also be explained by this association. Diabetes can also appear as a complication of tabes if the tabetic process invades the centers that preside over the sugar processes in the body.

Laryngoscopy in Children. A. Kirstein.—The autoscope devised by Kirstein merely depresses the tongue in a deep groove running to the epiglottis, which is automatically raised by the pressure. Gentle pressure on the prominence of the thyroid cartilage forces the anterior glottis well into view, and the entire throat can be inspected with remarkable ease no matter how much the child may resist. The entire larynx can be examined by this means in children of all ages, even from birth, although practice of the technique on the cadaver is an important aid. The autoscope was described in full and illustrated in the *Cbl. f. Kinderheilk*, 1899, 12, and experience is confirming its harmlessness and value.

Ziegler's Beitraege f. A. Path. (Jena), XXVIII, 3.

Transplantation of a Piece of the Colon in the Stomach. H. Reerink.—A piece of the colon, connected with its mesocolon, was transplanted into the anterior stomach wall to close a large defect, in numerous experiments on shepherd dogs. One of the animals, killed four weeks later, showed that the transplanted piece had healed perfectly into place and continued its function. Other experiments with a flap without a pedicle were less successful; the omentum became adherent to the stomach wall and the piece of intestine shrivelled and was absorbed. Experiments on the cadaver demonstrated that a large expanse of the anterior stomach wall can be substituted without technical difficulty. The transverse colon is peculiarly suitable for the purpose on account of its size. Other dogs thus operated on are still under surveillance at Freiburg to determine the remote fate of the transplanted flaps, which will be reported later.

Gazetta Degli Osp. (Milan), January 3.

Differentiating Receptacle for Gonorrheal Urine. I. Castracane.—The patient urinates directly into a flaring tube 2 cm. in diameter, holding about 300 c.c. It is bent into the shape of three Us in a row, thus automatically separating the urine into three portions, each of the same height and volume, easily inspected through the glass, which is graduated. Tests with colored fluids showed that the contents of the first loop are forced into the second and on into the third loop without blending with the following portions of fluid, although it is poured into the receptacle in a continuous stream.

Anales Del Circ. Med. Arg. (Buenos Ayres), December.

Serotherapy for Anthrax in Man. F. Dasso.—The anti-anthrax serum prepared by Mendez is much more powerful than Sclavo's or Sobernheim's. Dasso reports 130 cases treated with it, with the constant result of falling temperature, disappearance of the edema, general improvement and resolution of the ganglionary infarct. Nine of the patients died, all but two from secondary infection. The remainder of the cases all testify to the efficiency and specific character of Mendez's serum. The dose is 10 c.c., injected subcutaneously.

Antitoxin for Mosquito Bites. Voges.—Naphthalan is the substance which Voges calls an antitoxin for mosquito bites. He states that its action on the poison from the bite is as effective and specific as that of an antitoxin on the bacterial toxin. Voges is at the head of the National Department of Hygiene of the Argentine Republic.

Experimental Embolism of the Coronary Arteries. A. Foxt.—The functional and anatomic alterations caused by embolism of the coronary arteries have been studied by Foxt on large dogs. He introduced minute seeds into the coronary arteries through the aorta. When the main stem of the anterior branch of the left coronary artery was completely occluded, death ensued in eight minutes from arrest of the heart, but when smaller ramifications were involved, survival for several days was possible. The obstructions in the finer branches disturbed the functioning of the neuromuscular apparatus of the heart and interfered with the establishment of collateral circulation. Marked arrhythmia and diminished systolic elevation were produced in every case and also pronounced mechanical dilatation of the cavities of the heart, especially the left ventricle, but these symptoms passed away as collateral circulation was established. There was always extravasation of blood around the occluded points and patches of anemia in the myocardium. Comparison of the results of this experimental research, and clinical experience of thrombosis and sclerosis of the coronary arteries, demonstrates that the chief cause of the disturbances in each case is the general, persisting anemia in the myocardium. The entire syndrome, subjective and objective, is the consequence of the intense disturbance of the tonicity of the muscle, resulting from this anemia, and the disturbed tonicity entails various degrees of mechanical dilatation of the different cavities of the heart. The collateral circulation that may finally be established is evidently inadequate for the maintenance, although it may sometimes prove sufficient for the regulating function of the heart under ordinary circumstances. Foxt's experiments also demonstrate a certain periodicity in the symptoms observed, which explains the fact that alterations in the coronary arteries are sometimes found at autopsies when no symptoms had been observed during life, owing to the remission of the symptoms at the time of examination.

Change of Address.

N. M. Black, 1801 Grand Ave., to 177 14th St., Milwaukee, Wis.
M. R. Bailey, 4324 Market St., to 331 South 13th St., Philadelphia, Pa.

The Public Service.

Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., Feb. 7 to 13, 1901, inclusive.

George W. Adair, major and surgeon, U. S. A., member of a board at Fort Sheridan, Ill., to examine enlisted men for promotion.

Max A. Becher, acting asst.-surgeon, from Los Angeles to San Francisco, Cal., to accompany troops to Manila, P. I., and for subsequent assignment in the Division of the [illegible]

William H. Corbusier, major and surgeon, [illegible] board at Governor's Island, N. Y., to examine [illegible] mended for commissions.

William D. Crosby, captain and asst.-surgeon, U. S. A., as Corbusier above.

Guy L. Edie, major and surgeon, Vols., relieved from further duty in the Division of the Philipines and assigned to temporary duty in the Department of California.

Louis T. Hess, lieutenant and asst.-surgeon, U. S. A., member of a board at San Francisco, Cal., to examine enlisted men for promotion.

John Van R. Hoff, major and surgeon, U. S. A., member of a retir[illegible] D. C.

J[illegible]rgeon, U. S. A., from Chicago, Ill., to [illegible]port to the Surgeon-General for instructions.

James C. Merrill, major and surgeon, U. S. A., member of a retiring board in Washington, D. C.

Robert W. Morgan, dental surgeon, U. S. A., from Lynchburg, Va., to report at Washington, D. C., to the Surgeon-General for instructions.

Edward R. Morris, captain and asst.-surgeon, U. S. A., in addition to his present duties, to act as examiner of recruits at the city of Detroit, Mich.

Edward L. Munson, captain and asst.-surgeon, U. S. A., leave of absence granted on account of sickness.

Robert T. Oliver, dental surgeon, U. S. A., from Indianapolis, Ind., to Washington, D. C., to report to the Surgeon-General for instructions.

William E. Purviance, captain and asst.-surgeon, U. S. A., member of a board at San Francisco, Cal., to examine enlisted men for promotion.

Charles Richard, major and surgeon, U. S. A., member of a board at Fort Leavenworth, Kan., to examine enlisted men for promotion.

Samuel S. Turner, acting asst.-surgeon, member of a board at Fort Sheridan, Ill., to examine enlisted men for promotion.

Robert Winn, acting asst.-surgeon, member of board at Fort Leavenworth, Kan., to examine enlisted men [illegible]

In addition to the above the following [illegible]ers were appointed to membership on boards to [illegible] 1, 1901, at the stations designated, for the mental and physical examination of such candidates for the Military Academy as may be authorized to appear before them; Major John M. Banister, surgeon, U. S. A., and Lieut. Franklin M. Kemp, asst.-surgeon, U. S. A., at West Point, N. Y.; Acting Asst.-Surgeon John S. Fogg, at Fort McHenry, Md.; Maj. William O. Owen, surgeon, U. S. A., at Fort Thomas, Ky.; Capt. Harry M. Hallock, asst.-surgeon, U. S. A., at Fort McPherson, Ga.; Maj. Aaron H. Appel, surgeon, U. S. A., at Jackson Barracks, La.; Maj. Charles B. Byrne, surgeon, U. S. A., at Fort Sam [illegible] Henry I. Raymond, asst.-surgeon, U. S. A., [illegible] Maj. Marshall W. Wood, surgeon, U. S. A., [illegible] Mo.; Maj. Charles Richard, surgeon, U. S. A., at Fort Leavenworth, Kan.; Capt. Alfred E. Bradley, asst.-surgeon, U. S. A., at Fort Snelling, Minn.; Lieut.-Col. Henry Lippincott, deputy surgeon-general, U. S. A., at Fort Logan, Colo.; Acting Asst.-Surgeon Carle E. Bentley, at Fort Logan H. Roots, Ark.; Maj. John D. Hall, surgeon, U. S. A., at the Presidio of San Francisco, Cal., and Maj. Louis S. Tesson, surgeon, U. S. A., at Vancouver Barracks, Wash.

Special Order, No. 218, Headquarters Division of the Philippines, Manila, P. I., Dec. 21, 1900, reads as follows: Upon recommendation of the chief surgeon of the Division, the following named acting asst.-surgeons, U. S. A., are authorized to proceed to Manila and report to the president of the army medical board constituted by *paragraph 12, Special Order, No. 15, current series, headquarters* of the army, for examination for appointment as asst.-surgeons, U. S. A., and upon completion thereof will return to their proper stations, the travel expenses involved to be defrayed by applicants under paragraph 1395 of the Regulations: Department of Northern Luzon, George M. Ekwurzel, Isador M. Unger, Ernest F. Slater, Lorin B. Ohlinger, James F. Edwards and U. S. Grant Deaton; Department of Southern Luzon, Frank T. Woodbury and Wilmont E. Brown; Department of the Visayas, Paul R. Fletcher. Applicants, before leaving their stations, will file with the chief surgeon of their respective departments, by telegraph if practicable, a certificate that they intend to appear before the board on arrival at Manila.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ending Feb. 16, 1901:

P. A. Surgeon C. P. Bagg, detached from the Cavite Naval Station and ordered to the *Culgoa*.

P. A. Surgeon A. R. Alfred, detached from the *Culgoa* and ordered to the Naval Station, Cavite, February 7.

Surgeon C. Biddle, detached from the Naval Hospital, Norfolk, Va., and ordered home to wait orders.

Surgeon D. O. Lewis, detached from the *Iowa* and ordered to the [illegible] ry 13.

[illegible] rnold, detached from duty at the Naval Re- [illegible] Chicago, Ill., March 1, and ordered to the [illegible] for Manila, March 15.

[illegible] flith, detached from the *Prairie*, when put out of commission, and ordered to duty under the Bureau of Medicine *and Surgery.*

Surgeon F. J. B. Cordeiro, detached from the *New Orleans* and ordered home and to wait orders.

Surgeon A. M. Moore, retired, ordered to duty at Naval Recruiting Rendezvous, Chicago, Ill., March 1.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S Marine-Hospital Service for the seven days ended Feb. 14, 1901:

Surgeon H. W. Sawtelle, granted leave of absence for thirty days from February 20.

Surgeon P. C. Kalloch, granted leave of absence for three days from February 17.

P. A. Surgeon H. D. Geddings, granted leave of absence on account of sickness for eight days from January 26; granted leave of absence for thirty days from February 3.

P. A. Surgeon C. H. Gardner, granted leave of absence for seven days.

Asst.-Surgeon H. B. Parker, to proceed to Gulf Quarantine and assume temporary command of the service during the absence on leave of the medical officer.

Asst.-Surgeon *Dunlop Moore, to proceed to Port Townsend,* Wash., and assume temporary command of the service during the absence on leave of the medical officer in command.

Asst.-Surgeon G. W. McCoy, granted leave of absence for fourteen days from March 18.

Health Reports.

SMALLPOX—UNITED STATES.

California: Oakland, Jan. 12-26, 4 cases.
Florida: [illegible] 2-9, 2 cases.
Georgia: [illegible] 7, 2 cases.
Illinois: [illegible] 9, 8 cases; Chicago, Feb. 2-9, 2 *cases;* Pulask. [illegible] 5 cases.
Iowa: Ottumwa, Jan. 5-26, 2 cases.
Kansas: Lawrence, Feb. 2-9, 3 cases; Wichita, Feb. 2-9, 9 cases.
Kentucky: Lexington, Feb. 2-9, 1 case.
Louisiana: New Orleans, Jan. 2-9, 14 cases, 4 deaths.
Minnesota: Minneapolis, Jan. 26-Feb. 9, 9 cases.
Mississippi: Vicksburg, Feb. 2-9, 4 cases, 2 deaths.
Nebraska: Omaha, Feb. 2-9, 8 cases.
New Hampshire: Manchester, Feb. 2-9, 26 cases.
New York: New York, Feb. 2-9, 17 cases, 6 deaths.
[illegible] 2-9, 2 cases; Cleveland, Feb. 2-9, 48 cases [illegible] 2-9, 1 case.
[illegible] Feb. 2-9, 5 cases.
Tennessee: Memphis, Feb. 2-9, 16 cases; Nashville, Feb. 2-9, 9 cases.
Utah: Salt Lake City, Feb. 2-9, 32 cases.

[illegible] AND INSULAR.

Austria: P [illegible] 7 cases.
China: Ho [illegible] case.
Ecuador: Guayaquil, Nov. 24-Jan. 5, 25 deaths.
Egypt: Cairo, Jan. 1-7, 1 death.
England: London, Jan. 19-26, 3 cases; Newcastle on Tyne, Jan. 19-26, 5 cases.
France: Paris, Jan. 12-19, 6 deaths.
India: Bombay, Jan. 1-15, 6 deaths; Calcutta, Dec. 29-Jan. 5, 96 deaths; Karachi, Dec. 23-Jan. 6, 7 cases, 3 deaths; Madras, Dec. 15-Jan. 4, 3 deaths.
Mexico: Merida, Dec. 20, 1900, epidemic; Tuxpan, Jan. 28-Feb. 4, 3 deaths.
Porto Rico: Ponce, Feb. 8, 22 cases.
Russia: [illegible] 12-19, 4 cases; Odessa, Jan. 12-19, 31 cases, 5 death [illegible] 5-19, 6 cases, 2 deaths.
Scotland: [illegible] 1, 180 *cases.*

CHOLERA.

India: Bombay, Jan. 1-15, 9 *deaths;* Calcutta, Dec. 29-Jan. 5, 31 deaths; Madras, Dec. 15-Jan. 4, 19 deaths.

PLAGUE.

China: Hongkong, Dec. 29-Jan. 5, 2 cases, 2 deaths.
England: Hull, Jan. 30, 2 deaths, crew of steamship *Friary.*
Wales: Cardiff, Feb. 8, 1 death.
India: Bombay, Jan. 1-15, 550 deaths; Calcutta, Dec. 29-Jan. 5, 28 deaths.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, $2.50. Subscriptions may commence at any time. Volumes begin with the first issue of January and of July.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The qualifications for membership require that the applicant be a member, in good standing, of a state or local medical society entitled to send delegates to the annual meeting of the American Medical Association. A list of these societies will be sent on request. Applications must be accompanied with a certificate showing that the *applicant is a member of a recognized society,* and should be sent with the annual dues—five dollars—to the treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago. Members receive The Journal free. Subscribers to The Journal may become members of the Association without additional expense if they are members of medical societies recognized by the Association. Those desiring to have their names transferred from the *subscription to the membership lists should send certificates* as above, with a receipt for their subscription to The Journal, covering the current fiscal year.

FISCAL YEAR.

The fiscal year of the American Medical Association is from January 1 to December 31; and the annual dues paid by a new member cover only the fiscal year, no matter at what time of year the membership is obtained. Those who pay their dues and join the Association at the annual meeting in June, for instance, *pay only for the fiscal year* which ends with the December following, and the annual dues for the following fiscal year are payable the succeeding January, at which time the treasurer sends a statement to each member. Such members, however, are entitled to The Journal for the full year, even though the membership be not continued.

PAPERS READ AT THE ANNUAL MEETING.

"Every paper received by this Association and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the Association. . . The Board of Trustees shall have full discretionary power to omit from the published transactions, in part or in whole, any paper that may be referred to it by the Association or either of the Sections, unless specially instructed to the contrary by vote of the Association." (From Article V of the By-laws.)

NEWS.

Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

ORIGINAL PAPERS.

Articles are accepted for publication with the understanding that they are contributed solely to this journal.

COPYRIGHT.

Matter appearing in The Journal of the American Medical Association is covered by copyright, but as a general thing, *no objection will be made to the reproduction of anything appearing* in its columns if proper credit be given.

CONTRIBUTIONS TYPEWRITTEN.

It will be satisfactory to all concerned if authors will have their contributions typewritten before submitting them for publication. The expense is small to the author—the satisfaction is great to the editor and printer. We can not promise to return unused manuscript.

Half-tones, zinc etchings and other illustrations will be furnished by The Journal when photographs or drawings are supplied by the author.

ADVERTISEMENTS.

Advertising forms go to press eight days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. Advertising rates will be made known on request.

CHANGE OF ADDRESS.

In ordering a change of address it is important that both the old and new addresses be given.

REMITTANCES.

Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "Journal American Medical Association," except those for annual dues. These should be made payable and sent direct to the Treasurer, Dr. Henry P. Newman, 100 Washington Street, Chicago.

The Journal of the
American Medical Association

Vol. XXXVI. CHICAGO, ILLINOIS, MARCH 9, 1901. No. 10.

Original Articles.

SANITATION AND PROGRESS.*

WALTER WYMAN, M.D.
SURGEON-GENERAL, U. S. MARINE-HOSPITAL SERVICE.
WASHINGTON, D. C.

Some four years ago, at the meeting of this Congress in the City of Mexico, I had the honor of addressing you upon the subject of "International Responsibility with Regard to Epidemic Diseases." Quite in line with the thoughts then expressed, I have chosen for my subject to-night "Sanitation and Progress," and it will be my effort to show the interdependence of municipal, national, and international effort in the great undertaking of the elimination of contagious disease, and that the twentieth century should witness this achievement.

Each morning I open on my official desk a package of newspaper clippings, containing notices of the prevalence of the several contagious diseases throughout the whole United States; and, as I note the varying recurrence of smallpox, diphtheria, typhoid fever, and scarlet fever, the notes upon consumption, the alarms concerning yellow fever and the bubonic plague, the thought which is impressed upon me is how seriously are we lacking in proper effort in suppressing these suppressible diseases. Nothing seems easier to me than the prevention or suppression of smallpox. In vaccination we have an absolute preventive, and in the glycerinized lymph we have a safe inoculating material absolutely devoid of the danger of exciting undue inflammation. Thus a mere scratch or a needle puncture insures, without discomfort, protection from one of the most loathsome and disfiguring diseases known. Even after smallpox has become epidemic, the methods by which it may be rapidly and surely suppressed have been so frequently demonstrated as to become now almost a matter of mere routine.

The antitoxin for diphtheria has long passed the experimental stage and is now justly regarded as a specific—a trusty addition to the armamentarium of the physician and sanitarian.

In the treatment of the other diseases mentioned, we have for bubonic plague a specific cure and preventive, and are certainly on the verge of the discovery of specific remedies for both tuberculosis and typhoid fever, but even without these specific remedies the nature of the diseases are thoroughly understood and the methods of the prevention of their spread are accurate and well known.

Then why do these diseases persist? The answer is plain. It is that sanitary administration has not kept pace with scientific knowledge. It is also evident that this scientific knowledge is not so widely diffused as it should be, even among those of whom we have a right to expect it. It is evident that we are not making "use of those means which the God of Nature has placed in our power."

MUNICIPAL SANITATION.

With regard to cities, there is a marked necessity of a strong public sentiment requiring that municipal cleanliness shall rank as one of the foremost features of municipal government. This is a field, not for the national government, but distinctively for the states and municipalities, whose degree of sanitary excellence is a fair exponent of their civilization and culture, for each state and each municipality has, and will continue to have, a degree of sanitary excellence commensurate only with the demands of its own people.

We have here a striking illustration of the fact that our governments are governments of the people. It is, therefore, necessary to cultivate among the people a demand for municipal sanitary excellence and as great an abhorence of municipal filth or neglect of sanitary engineering as there is of uncleanly dwellings or of uncleanliness of person.

A good water-supply, perfect sewerage and disposal of garbage, good street paving and street cleaning, should be the first boast of every municipality. Let these be pointed to with the pride which is commonly bestowed upon great public institutions and buildings. I see no reason why slums should be allowed in any city. Relatively speaking, too much attention is paid to public parks and handsome municipal buildings. The city's improvements should be in the alleys, around the docks, in the tenement-house quarters, and great as may be the appreciation of public art as manifested by statues and public gardens, and of the parks and the boulevards, let these wait upon the less showy but more important features of municipal life.

Recently I was on a board of three, the other two members being noted architects, to decide upon plans for the great government hospital for the insane, near Washington, Congress having appropriated $1,000,000 for doubling the capacity of the present institution. In looking over the numerous plans and sketches submitted by the half-dozen competitors, I was impressed with the promptness with which these two noted architects pounced upon all faults relating to light and ventilation, particularly of the lavatories, quickly throwing out as unworthy of further consideration those plans which placed the toilet-rooms in dark or badly ventilated positions. This illustrates the advanced modern idea, particularly when you reflect that formerly any dark or out-of-the-way place was considered proper for these necessities of habitation. So, too, in practical hospital work, it has been my observation that dark closets are wont to be the repositories for old mops, rags, and dirt, so that it was my rule, when engaged in the management of hospitals, to paint the darkest and worst closets a pure white, making immediately perceptible the slightest trace of dirt or filth. The trouble I had experienced with these closets soon vanished.

---

* Read before the Third Pan-American Medical Congress, held in Havana, Cuba, Feb. 4-7, 1901.

These illustrations will serve with regard to cities. The chief attention should be centered upon the worst parts of the city. The sewerage, paving, light and ventilation of the worst sections should receive the first and most constant attention. In support of this idea, I quote from an article written five years ago by Dr. John S. Billings, who says:

> As regards Asiatic Cholera, typhoid fever, various forms of diarrheal and dysenteric diseases, and diphtheria, our knowledge of their causes, means of communication and prevention is much in advance of the actual practice of most communities, mainly because the methods which are known to be effective to secure constantly pure water supplies and the satisfactory removal and disposal of refuse and excreta require considerable sums of money to establish and to maintain, and the public has not yet arrived at the conclusion that such expenditure is wise and proper and that taxation for such purposes is necessary to secure the prosperity of a community.
>
> A very considerable part of the excess of death rates in a city is due to the poverty of the inhabitants of certain sections of it. In certain parts of all large cities there are to be found a number of people who are insufficiently fed and clothed and who are huddled together in such a way that cleanliness, decency and morality are difficult or impossible to obtain. Here congregate the idle and intemperate, the tramps and loafers of the country, the hereditarily indolent and vicious classes. Mingled with them and living under much the same conditions are many honest and industrious people who are living from hand to mouth; the daily wage earners to whom sickness means recourse to the public hospitals and loss of means to earn their own subsistence. The death rates in these quarters are fifty to one hundred and fifty per cent. greater than those of the better class of population; the average duration of life is from ten to fifteen years less by reason of such poverty and squalor, a large part of their sickness must be relieved by public charity and one-third of those who die among them must be buried at public expense.
>
> The problem of how to improve the sanitary condition of these quarters to prevent the increase of foul, damp, dark and overcrowded dwellings and thus lessen the burden of the community, without still further pauperizing the people and attracting to the place other vagrants and criminals, is one of the most serious that confronts modern civilization and municipal government.
>
> It is easy to prove to any intelligent business man that high death and sickness rates in a city imply heavy demands on the public purse in the maintenance of hospitals and other charities, and also to show that an abundant and pure water supply, clean streets, good sewerage and good and well enforced building regulations are among the best means of lowering these death and sickness rates.

WRONG METHODS.

The foregoing quotation suggests a conviction which has long been forced upon my mind, that in all our sanitary work, both in municipal sanitation and in quarantine, we are working at the wrong end of the line. We are treating symptoms instead of the original cause of the disease, and both for sociologic and economic considerations it would be far better to change the point of our attack.

Let me illustrate by the quarantine methods heretofore in vogue, those now and in the future to be utilized in the suppression of an epidemic disease such as yellow fever. When yellow fever appeared in a given locality under the old dispensation, shotgun quarantines were established by near and remote localities having any possible communication therewith. The press dispatches announced that "Podunk," evidently priding itself on its vigilance, "has quarantined against the world," and other communities, not to be outdone by Podunk, followed suit. I do not mean to ridicule these measures, but how much wiser is the method now enforced of concentrating the restrictive efforts in the neighborhood of the epidemic, and how much wiser still will be those provisions of the near future which will enable any community, by reason of its good sanitary condition, to look with comparative equanimity upon the chance introduction or outbreak of a contagious disease.

And in our municipalities we build large public hospitals and establish other charitable institutions for the reception of the people whose unfortunate condition is attributable in a large measure to the insanitary conditions which our municipal governments allow to persist. As an economic measure, therefore, as shown by Dr. Billings, it will in the long run be profitable to spend more upon sanitation; and from a sociologic standpoint the advantages of this policy will be no less marked, for it must have occurred to most of my hearers in their hospital experiences that the greater the number of charity hospitals that are founded the greater will be the number of people who are willing to become the recipients of charity; and that while charity is to be commended the zeal manifested therefor may, after all, bring unfortunate results, for "zeal without judgment is a fault, even though it be zeal unto good."

SANITATION VERSUS QUARANTINE.

Another strong appeal for sanitation lies in the promise which it would give of getting rid of quarantine. The time is at hand when we must consider the necessity of ridding ourselves of these restraints upon commerce, of holding a ship with its valuable cargo and eager passengers, in quarantine because some person is aboard who has resided in a filthy section of a foreign port and has brought with him an infectious disease. For these diseases can generally be traced to the overcrowded and otherwise insanitary sections of a city, the sections which, as I have before stated, should receive our first consideration. And the rich man held on board a steamer in the upper cabin because of infection aboard his ship in the steerage may reflect that his detention is due primarily to the faulty sanitation of some miserable portion of some foreign city, and he receives thereby a demonstration of his personal interest in these conditions.

It is an interesting matter for conjecture—what would be the effect upon the prevalence of contagious disease if there could be a complete wiping out of all slums and low tenement-house districts in all our cities. It matters not that an epidemic once started may prevail as violently, or more violently, in the better portions of a city, and that cleanliness and sanitation may then have but little effect upon its progress. The fact remains that for the perpetuation of these diseases among the people filth and bad environments are essential, and when we reflect how easy and natural is the upward gradation of infection, how readily through successive grades it may ascend the social scale from the lowest to the highest, the direct and personal interest of the wealthy and more intelligent classes of a community in the condition of the poor and ignorant becomes manifest. The greater danger of contagious disease among the poor is recognized in the present U. S. Treasury quarantine regulations, providing for the inspection of vessels at foreign ports bound for the United States. These regulations require, under certain circumstances, the inspection of the steerage but not of the cabin passengers. We have made a class distinction, notwithstanding our democratic ideas, but the regulation is based on knowledge. It is a recognition of the fact that contagious and loathsome diseases are more apt to be prevalent among the poor, not simply because they are poor but because they have been crowded and prevented from living under as good sanitary conditions as the more favored classes.

That good sanitary environment, enhancing the general health, is the best means of eliminating contagious disease, is illustrated by a conversation which I have had within a week with the director of the Hygienic Laboratory of the U. S. Marine-Hospital Service, Dr. Rosenau, who has just returned, after a prolonged period of study and investigation in the Pasteur Institute in Paris. On inquiring as to the latest phases of scientific investigation and the trend of thought at this great intellectual center, among other matters, he stated that there seems to have arrived a period of pause in bacteriology, or at least a spirit of inquiry as to the true relation of microbes to the diseases of which they have been considered the special agents. Dr. Rosenau's statement is as follows:

VIEWS ON ORIGIN OF CONTAGION.

> We have lately been compelled to modify some of our notions of the causes of contagious and infectious diseases. After the brilliant discoveries by Pasteur and Koch it was thought that the presence of the pathogenic microbe organism was like the bite of a venomous snake, surely poisonous. But now we know that there are other conditions besides the presence of the microbe necessary to produce disease. Many people go about with virulent diplococci of pneumonia in their respiratory tract but do not have pneumonia. Why? Because their cells are vigorous enough to prevent the diplococci invading the lungs, but put such a person under bad sanitary conditions or depress his vitality and the microbes are not phagocyted—they invade the lungs and pneumonia and death follow.
>
> The same, to a limited degree, occurs with the bacillus diphtheriæ.
>
> In times of cholera epidemics men go about with living, virulent, cholera vibrio in their intestinal canal, yet they are not sick. Why? Because the conditions for the production of the cholera toxins are not favorable—there is no abnormal flora in their intestinal canal. But let such a person eat poor and tainted food or derange his digestion through indiscretion or evil sanitary surroundings and the disease results.
>
> Many people live a long and active life with tubercle bacilli encysted in the apex of one lung. As long as they have plenty of fresh air and sunshine and good sanitary surroundings they remain well. But give such a person poor food or bad sanitary surroundings and see what happens. The battle going on between the bacilli and the cells results in a victory for the bacilli. The cells die and the victorious bacilli spread havoc through the lungs. We, therefore, have a scientific proof of the sense of the old-time notions of the old-fashioned doctors who taught the value of fresh air and sunshine, of good food and exercise, of cleanliness and dry dwellings, and we find that the conditions of health which result from such good sanitary conditions are after all among the very best preventives against infection.

Another good effect of sanitary excellence would be to obviate municipal deception either in the concealment of the existence of contagious disease or by reports giving a sense of false security to other communities. This subject is one which time will not permit me to discuss, but was treated of at some length in an address which I had the honor of delivering before the Social Science Association, in Washington, D. C., last May. I will simply say that the greater the neglect of sanitation, the more pronounced the disease-bearing factors of a city, the more sensitive does it seem to the acknowledgment of the presence of contagion, the more determined does it become in outright denial. It is thus seen, and it is by no means a matter of imagination, that municipal morality is affected by the municipal sanitary status.

WHO SHOULD BE SANITARIANS.

In the sanitary progress of the new century, it has occurred to me, there must be developed new classes of individuals in sanitary affairs. To-day every physician is considered, in a sense, a sanitarian; then there are the professional sanitarians, represented chiefly by those holding sanitary office; but there are very few men to-day engaged in legislation who give any thought to sanitary legislation. We need a classs of men who are versed in the law, who are skilled in framing laws, and who are familiar with the difficulties and methods of securing their enactment. The average doctor or sanitarian is as a child in these matters. Impressed with the importance and nobility of his cause he becomes oblivious to the sentiments or even the rights of those affected unfavorably thereby. The same influences which seem to make of the doctor a poor man of business seem to make of the average sanitarian a poor man for legislation. So that it seems to me, at least in the United States, it will be necessary in the development of the ideal sanitary legislator to look for him among the lawyers rather than among the physicians. There is no reason why a good lawyer should not become an adept in sanitation. I believe it to be more difficult for a good doctor to acquire legislative wisdom.

Another class of men whom we should look to for aid are the men of extreme wealth. I believe their attention should be directed to the vast amount of good to be done by the employment of their capital in backing up sanitary improvements. The number of great fortunes possessed by individuals in our several republics, I have not had the opportunity of learning, but they are numerous; and so far as I can judge, their possessors, at least a large number of them, are imbued with generosity and a desire to utilize their great wealth for the public good. Witness the large number of universities founded by wealthy men, the public libraries, and other institutions, erected or endowed by them; the contributions which they make in times of great calamity and in ordinary times to all charitable undertakings.

The methods by which they may assist in public sanitation may not be so obvious or numerous as other methods of advancing the public welfare, yet the influence of a man of great wealth could be distinctly felt in the advancement of sanitary legislation, and in the perfection of sanitary administration. Moreover, the use of large capital in the improvement of the dwellings of the poor appears to me to be as sensible and noble a method of the employment of capital as can be found. It has been a matter of surprise to me that the attention of our wealthy men of philanthropic impulses has not been more frequently thus directed. The Mills Buildings in New York City in a measure illustrate this idea, and I doubt not that a proper inquiry into the subject would develop other illustrations. But the advantage which individual capital enjoys over municipal government in the improvement of the dwellings of the poor lies in the difficulty experienced by the latter in condemning and destroying unsuitable tenements. Capital can purchase them and erect good buildings in their stead. This is illustrated by the history of a company formed, and now being successfully operated in Washington, D. C., for the erection of suitable habitations for the poor, with less thought of profit than of public benefaction. As originally outlined, the scheme included a condemnation by the commissioners of the District of Columbia and a destruction of the condemned insanitary buildings and the erection in their place of buildings by the company, though owing to legal difficulties the necessary legislation for destruction has not yet been enacted.

In a recent press clipping I have read that statistics just compiled show that during the year just past contributions to educational, religious and charitable objects and institutions in the United States have amounted to almost $61,000,000, donations of less than $1000 not being included in this summary. The article further states that this showing seems to indicate that there is a growing disposition to make philanthropy a partner of prosperity, a tendency to give helpfully instead of pauperizing men by benefactions. But in the list of these benefactions I see no mention of purely sanitary gifts or endowments, and to my mind it seems a reasonable proposition that more practical and beneficial results would have been obtained if this $61,000,000, instead of being expended upon educational, religious and charitable institutions had been expended upon reclaiming the slums, and in the purchase and destruction of rookeries, with the erection in their stead of modern sanitary tenement-houses, and that, too, even though the money had not been expended outright as a gift, but as a safe though moderately paying investment.

SANITARY TENEMENTS.

The need of sanitary tenements has been brought to the front by the recent agitation and widespread movement for the suppression of tuberculosis. In a pamphlet on the tenements and tuberculosis, by Dr. S. A. Knopf, of New York City, appears the following statement: "The present condition of the tenement houses in this city is so serious that the evils arising therefrom are a distinct menace to the welfare of the community. There are at present over 44,000 tenement houses in the old City of New York, and new tenement houses are being erected at the rate of about 2000 a year. These are, in many respects, worse than the old buildings erected thirty years ago. They are badly constructed, and so planned that many rooms depend for their light and air upon long, narrow, dark, air-shafts, which, instead of giving light and air, are merely stagnant wells emitting foul odors and diseases."

It is true that restrictive legislation may be enacted, but in view of all the foregoing facts can there be found a more useful method of employing great individual wealth than in the removal and the prevention of the erection of such houses by the substitution of those properly constructed.

In a recently published article by Charles R. Henderson, Professor of Sociology in the University of Chicago, on the spirit of modern philanthropy, the writer states that "philanthropy has taken a wider and nobler view of its mission. It has become preventive and educational." He quotes Miss Carpenter, as follows: "A hospital can not cleanse a poison-infected district, nor diminish the constant supply of patients from an undrained and malarious locality." He further says: "It is well to remove the weak and tempted from bad environment, better still to improve the environment. It is well to go down to the folk-swamp and rescue one here and there; better still to drain the cesspool, improve the tenements, prevent adulteration of food and drink, inspect factories and compel use of devices for averting accident and disease. The wall at the top of the dangerous precipice is worth far more than an ambulance at the bottom.

Since the above lines were written I have read a letter from a special correspondent (Marshal Lord) of the Washington *Evening Star*, of January 19, showing the reformatory work of this character now going on in London, which should certainly stimulate all American municipalities to efforts in the same direction. The writer states that:

> Every American city big enough to have one of those municipal sores called a slum will doubtless be interested in the huge experiment London is undertaking. This is nothing less than the expenditure of ten millions of dollars in the wiping out and rebuilding the homes of about forty thousand people. A further program that means the expenditure of another ten millions is now being discussed, and, after these projects are well under way, new schemes will be planned to the same end and more millions spent until the necessity for spending money in this way in London shall have disappeared and the city have become a landlord on an unprecedented scale. To-day the housing problem is the worst that London has to face, but her powerful county council, which has done several rather remarkable things already, and which has practically unlimited wealth to draw upon, has determined that overcrowded, insanitary, and slum areas must go. The County Council has already attacked, razed and rebuilt one of the worst slums in London. Several other notorious ones are now being torn down and still others are doomed. Medical inspectors in the County Council's employ are penetrating into the city's filthiest corners and condemning them. The wretched creatures who swarm in them are paid a small sum of money and turned out, after which the slum comes down. The "before taking" phase of the Council's heroic remedy is a mass of closely packed hovels, squalid, unlighted and unventilated, reached through grimy, winding alleys, in which the police dare to go only in force. The "after taking" is blocks of trim cottages or apartment buildings, each separated from the other, equipped with literally every modern convenience, including a perfect system of drainage and every essential for cooking. The apartments are well lighted by day with large windows; at night either by gas or electricity on the slot system where a penny dropped in produces gas for six hours. These model dwellings, moreover, are to rent at prices which even very poor people can afford to pay and are immediately tenanted to their full extent.
>
> So far, on workingmen's homes of this pattern that occupy the place of former slum districts, the London County Council has spent a little over $3,000,000. It is now building houses which will cost over $1.500,000, and to clear the new districts, which have been condemned and which are to be rebuilt, will cost $5,500,000 more. The houses already built accommodate more than ten thousand people. Those now building and those arranged for will give dwellings to thirty thousand more. They will be finished and occupied in five years from now.
>
> The second scheme which the Council is laying out takes another way of curing the same disease of overcrowding. This is by acquiring tracts of land in the country just out of London, building model dwellings there and connecting them with the working centers of the city by light railways. This will probably cost $10,000,000 more.
>
> The Council began to rehouse on a modest scale in 1883, but the importance of its work to-day lies in the dimensions to which it has grown and its great promise for the future.

It is a significant fact, happily recalled at the present time, that the new King of England, Edward VII, was identified with the inception of this work. His maiden speech in the House of Lords in 1884 was in support of a motion in favor of the better housing of the poor, and he was subsequently one of the commission appointed to consider the matter.

It is thus seen that our brethren in the East are already in the field. Why stand we here idle? Shall we in our newer territory allow ourselves to be surpassed in these matters by older governments, less democratic than our own, less dependent upon the will of the people?

In the foregoing I have endeavored to show that public sentiment, law and administration are the most important factors for the attainment of our standard of sanitation.

ADMINISTRATION.

One more word with regard to administration. The health officers selected under state or municipal law are too frequently subject to political change. An experience of one term of service is generally necessary to sufficiently acquaint the health officer with the duties of his office, and while political changes in other offices may be made, possibly without injury to the public service, the same can not be said with regard to an officer of the public health. He should be selected, also, solely on account of his ability or special adaptability for the position, and while every American citizen may be expected to be a politician, in a certain sense the health officer should be one who is not devoted to politics. And here is where the great body of the medical profession can exercise a salutary influence by taking an active interest in these appointments, insisting that men of character, of education and reputation, should receive them, for it is the duty of the profession to uphold the health officer in the performance of his public obligations. The health officer and the boards of health should command the respect and receive the support of the practitioners of medicine whose influence in this direction is all powerful.

SANITATION AND POLITICS.

One word at this point with regard to sanitation and politics. The city of Washington is sometimes referred to as typifying the highest order of sanitary equipment and administration, and when it has completed its sewerage system and established its water filtration plant it will be a model city. But, it may be argued, it is a model city because, unlike others, it has no local politics. This is true, but if municipal politics seem to interfere, as they often do, with sanitary progress, it but serves to demonstrate a reason, in addition to many other reasons, why the best men should go into politics.

In the beginning of this paper I stated that municipal cleanliness and sanitation is not a field for the national government, but belongs distinctively to the states and municipalities. Doubtless there is suggested to you, as to myself frequently, the thought of the national government enforcing municipal sanitation. Speaking for the United States, under our constitution, it is impossible. Nor with our ideas of self-government is it desirable. A weak leaning upon the national government in ordinary matters affecting the people of a state or city is a thing to be avoided as lessening the feeling of municipal and personal responsibility for good government. The general government does not go into cities and say what kind of reservoirs they must have, how their sewers shall be laid and what disposal is made of their garbage. These are left to local governments, which are just as capable for these measures as they are for managing their own police and fire departments.

Yet in the exercise by the general government of its right to prevent the introduction of contagious diseases from foreign countries, or the spread of these from one state to another, I can foresee the possibility of such national action as may, without objection, have an influence on the sanitation of cities. The sanitation of seaport cities which habitually breed yellow fever, with a view to eliminating this disease, which interferes so seriously with commerce, is being seriously considered by thoughtful men interested in commerce, sanitation and diplomacy.

COMMERCIAL INTEREST IN SANITATION.

There is no one disease which interferes so seriously with commerce in the western hemisphere or causes greater panic than yellow fever. The interdependence among nations in the efforts to get rid of this disease has become strikingly obvious, and illustrates the unity of interests of the nations in sanitation.

Sanitation in Western Republics.—An inquiry into the sanitary conditions in the ports of the western republics will show, with regard to many of them, a woful sanitary condition, a neglect of the first principles of sanitation, and either faulty or entire absence of quarantine protection of one city from another. The commercial relations between these places are each year becoming more intimate, and through correspondence and conversation with representatives of the Central and South American republics, I learn that the same apprehension which is felt by the United States each summer is experienced by all. All, or nearly all, of our republics have suffered in their commercial and business prosperity through the visitation or threatened visitation of yellow fever, and I have been surprised by the instant approbation with which all with whom I have spoken received the idea of an international agreement looking to the sanitation of such seaports as are habitually infected with yellow fever. That yellow fever can be rooted out of an old endemic focus, I believe; but to demonstrate it is not an easy matter. I have endeavored within the past two years, through special reports from the United States consuls, to collect facts showing the relation between sanitary improvements and the prevalence of yellow fever in the principal fever ports of the tropics, but the results are as yet undeterminate. I believe, however, we have one notable illustration of success in Santiago, long known as a yellow fever port, but where the measures adopted by General Wood and the medical officers of the army were so radical and thorough that no yellow fever now prevails or has prevailed during the past year in that city. I feel confident, too, that in due course of time, and that before long, yellow fever will be made to disappear altogether from Havana. Reasoning somewhat by analogy, we should be able to exterminate yellow fever from a given locality. A year ago last July it appeared in the National Soldiers' Home, Hampton, Va., where there were 3500 veterans of the Civil War, but it was stopped, and that, too, quickly, with a record of forty-five cases and thirteen deaths. In June, 1896, it appeared at McHenry, Miss., and in twenty days was entirely suppressed, after the occurrence of twenty cases in all.

PROVISIONS IN ELIMINATING YELLOW FEVER.

In eliminating it, however, from a city or locality where it has prevailed for many years, there are four provisions which must be complied with: 1. Effective sanitary administration. 2. Good sewerage and water-supply, soil drainage and paving. 3. Sanitary engineering of harbors. 4. The destruction or scientific disinfection of houses where the fever has prevailed. In Havana the first of these requisites has been and is being accomplished. The city is clean on the surface. The sanitary administration is excellent, and measures are already under way for securing the second requisite of good sewerage, drainage and paving. I do not know that it has yet been determined whether sanitary engineering is necessary with regard to Havana harbor. But any harbor in the tropics which receives sewage, and is so land-locked that it becomes a cul-de-sac, must be subjected to such engineering as will cause a flow of its waters freely to the sea. But even when all this is done, yellow fever will still prevail unless the fourth measure is enforced, namely, the destruction of old infected houses and the thorough scientific disinfection of others too good to be destroyed. In a tropical city a few years ago, much stress was laid on the good results following sanitary improvements of the harbor, but their improvements went still further, namely, to tearing down a large number of old houses, which was immediately followed by an unusual outbreak of yellow fever. In other cities, I have been informed, millions of dollars have been spent in improving the sanitary conditions, yet yellow fever prevails from time to time, and why? Because the houses are infected, and have been for a great number of years.

MEANS OF DISINFECTION.

This brings to us the question: Have we a simple and efficient means for a scientific disinfection on this broad scale? I believe that we have. To the U. S. Marine-Hospital Service, which has had so large an experience in the post-epidemic disinfection of cities and towns, the thought of a simple, clean, non-injurious, inexpensive, yet thorough disinfection of houses, after its experience with the carting around of steam chambers, the burning of sulphur, and washing down with bichlorid solution and carbolic acid, and meeting the bills afterward presented for ruin or damage of property—the thought comes as a welcome relief.

A few years ago, through the inventive genius of one of our officers, we believed we had a formaldehyde lamp which met every requirement, but experience demonstrated certain defects which caused its temporary abandonment. The intelligent mechanic who constructed the lamp, however, has so improved it that thus far it has stood every scientific and practical test to which it has been put, and I hope and believe that in this lamp we have an efficient, simple and safe method of evolving formaldehyde gas of a strength to insure a thorough disinfection of houses and public buildings. I mention this matter as one of encouragement in the idea of eliminating yellow fever under the terms of the fourth requisite mentioned, from cities usually infected.

INTERNATIONAL AGREEMENT IN SANITATION.

The plan of international agreement which was outlined in an article by myself,[1] contemplates a convention to be composed of public sanitarians, civil engineers and financiers, whose duty it should be to prepare a treaty providing for the examination of the chief yellow fever ports by a commission representing the republics concerned. Each country should obligate itself to put into effect the measures recommended by this commission, or measures of its own which should meet with the commission's approval. Since obligations without penalties would be worthless, the treaty should provide that if after a sufficient time these improvements are not made, each of the other nations interested should impose such discriminative tariff or tonnage tax or quarantine restraint upon the offending nation as would cause it in its own interests to comply with the terms of the treaty. Since the publication of the *Forum* article, I have conversed upon the subject with a number of the representatives of the Central and South American republics, and with representative public men of our own country, and without exception all have pronounced the idea both valuable and practical.[2] If this measure should become an accomplished fact, think of the stimulation which, through international influence, would be given to municipal sanitation everywhere. Dr. Kober, in his excellent address on the "Progress and Achievements of Hygiene," gives in detail the beneficial results of the sanitation of European cities. In providing for sanitation of seaports on account of yellow fever, the cities would undoubtedly benefit with regard to other diseases, and there is no doubt that as a result their commercial prosperity would be so enhanced that other cities would take notice and profit by their example.

Standing on the threshold of the twentieth century, and looking forward to its achievements, the foregoing thoughts appear to lose the elements of doubt which may at first seem to attach to them, particularly when we look back upon the achievements of the past century in medicine, in surgery and in sanitary science. And when we study the achievements of other centuries of the past, and see how they have been filled with the more primitive struggles for individual and national freedom; with the evolution of physical and mental science; with the development of architecture, painting, sculpture, and literature, it would seem that the next great cause pressing for agitation, both for the amelioration of unhappy conditions and for further advancement along the lines of previous study and development, is the cause of sanitation. It is the next step for progress in the destinies of man for "elevation in the scale of being." For further intellectual and moral advancement sanitation is indispensable. Progress in other matters will in a measure depend upon it. The movement has already begun. Witness the sanitary benefactions of George Peabody in London, thirty-eight years ago, and the efforts of the London County Council, as previously narrated, and similar work in Liverpool, Glasgow, Paris, and Brussels; the valuable report of the New York Tenement House Commission of 1894, and the labors of the present commission; the report of Surgeon-General John M. Woodworth, U. S. M.-H. S., to the International Medical Congress in 1876; the resolutions of the Conference of Sanitary Officers, at Montgomery, Ala., in 1899, and of the American Public Health Association in 1896; the report of the U. S. Department of Labor upon the investigation of slums, under the authority of act of Congress; and the innumerable contributions on these subjects to the daily and medical press. All the above relate to the subjects which have just been under discussion, and the time has come for more positive action.

The twentieth century will certainly demonstrate the brotherhood of man; the fraternity of nations; and, not excepting even the Peace Conference at the Hague, there can be no more hopeful sign of promise than is held out by sanitation.

Here is a common field upon which the nations may meet with unselfish and common purpose; here is a policy which may well be put in the platforms of political parties, and which, by requiring intelligent legislation, will bring the best men into local politics; a policy which will put a rifle-groove in the shotgun now loaded with spasmodic municipal reforms, good government clubs, and crusades against vice, and weld these latter into one missile of definite direction and force. Here is a means by which the rich may help the poor without further pauperizing them; a cause, which, if advocated will break down unnecessary class distinction; a promise of greater public morality; an assurance of higher life and greater health and prosperity to all, embodying in it the *summum bonum* of human existence, "the greatest good to the greatest number."

---

[1] The Forum, February, 1899.

[2] A resolution embodying the plan as outlined above was adopted by the Pan-Amer. Med. Congress on motion of Dr. Eduardo Wilde, Argentine Minister to the United States and Delegate to the Congress.

RESULTS OF SURGERY IN THE AGED.*

JAMES P. TUTTLE, M.D.
NEW YORK CITY.

In the study of human longevity, it is not only a question of teaching young people how to grow old, but also old people to grow older. Old age with impaired faculties and physical infirmities is hardly a blessing to individuals or their friends. Many of the ailments to which old people are subject, which worry and distress them, tend to shorten life, are amenable to surgical treatment, and would be unhesitatingly so treated in young people, but which are left alone in them on account of the fear of operations and anesthesia on the aged.

The scriptural axiom, "three-score years and ten" as a reasonable limit to human life, has become so firmly imbedded in the layman's mind that those whose friends have approached this age generally feel that it is better for them to suffer what ills may have come to them, rather than take any chances in procuring aid from surgery. They hold that only a few years at best are left, and prefer to accept them, even with pain and worry, to taking the slightest risk of meeting death from surgical procedure. They are entitled to their judgment, but they should be guided by the accurate knowledge and experience of surgeons as to the exact risk they take. Many lives are lost or shortened by the excessive fear, both in the laity and the profession, of surgical procedure in the aged.

Certainly, a large number of painful affections, such as hemorrhoids, fissure, fistula, hernia, stricture, varicose veins, etc., often carry their victims to the grave, on account of the fear and inexperience of operators in operating on old people. All surgical procedures are hedged about with many conditions. The first, and of most importance, is the nature of the disorder. If this is fatal without operation, all other considerations must be laid aside, and the procedure which promises the best chance of prolonging life undertaken. If, however, the operation is one of election, and not of necessity, we must consider many things, e. g., the physical conditions, heart, lungs, brains, kidneys, etc.; then environment, for a suitable time and place is necessary for perfect results in surgery. Mental repose and absence of nervous tension are important adjuvants in the recuperative process. Sex and age are also to be considered. This last is frequently made the first in the consideration of a surgical operation. Many friends and surgeons leave old people to their fate, with the simple assertion: "Oh, he is too old for operation."

I do not propose to go into any elaborate statistics to discuss with you the influence of surgical operations on the aged, but my opportunities as visiting surgeon to the public institutions of my city, for the study of this subject, have been so unusual that I feel justified in letting these facts have a wider circulation than that of a purely clinical lecture. I shall quote no books nor authorities, but simply state facts which I have observed and the records gathered from hospital charts by persons entirely disinterested in proving any preconceived theories. The facts presented will embrace a brief statement of conditions determining surgical interference, and a tabulated statement of my past sixteen months' work.[1]

CONDITIONS DETERMINING OPERATION.

The old adage, "a man is as old as he feels and a woman as old as she looks," is one of the safest guides in surgery. I have found that sprightly, energetic, ambitious old men stand surgical procedures well, while wrinkled, dull-complexioned, weazened-faced, dried-up old women of lesser years succumb quite easily. On the other hand, well-preserved, healthy old women, with bright minds and clear complexions, are capital subjects for operation. In one such, 84 years of age, I operated at one sitting for double inguinal hernia nearly four years ago, with perfect success, and she is to-day one of the cheeriest, most grateful and happy patients I have.

The condition of the heart in determining on surgical operations is not nearly so important as the laity believe. Organic valvular diseases of the heart, unless of the most marked character, are not a bar to ordinary surgical procedures; fatty heart, and degeneration of the muscles, however, should be distinctly ruled out. As we will see later on, the condition of the kidneys is important, but the appearance of a slight quantity of albumin or an occasional hyaline cast in old people is not of any great moment, and these cases can generally be operated on with confidence.

In summing up these cases, I have made the arbitrary division of 50 years—above and below. Of those over 50 years old, I hold records of 130 cases, of which the average age is 65.8 years. If you take those above 60, there are 79 cases, whose average age is 69.8 years. Of those below 50, I have only completed the records of 76 cases, with an average age of 34.7 years. Many more have been done in this class, but I have not yet been able to complete the records.

The mortality class above 60 was 3 in the 131 cases. Two of these deaths were caused by pneumonia, due to the neglect of the orderly in one case and the unfortunate breaking down of the boiler and consequent exposure to great cold in the other. Several other cases of pneumonia occurred in the same ward from the same exposure, in people who had not been operated on. The third died from edema of the lungs, following operation, and on postmortem, showed chronic Bright's disease Two of these deaths were caused by pneumonia, due to the operation, which should not have been done. It was a mistake, due to the fact that the party whose duty it was to examine the urine did so carelessly or not at all, and made a report which was absolutely out of keeping with the patient's actual condition. The pneumonia cases can hardly be charged to the operations, as they were clearly due to causes beyond the operator's control.

The number of deaths in patients under 50 years of age was 3, making an average of nearly 4 per cent, considerably larger than that in the older class. One of the deaths in this class was due to the same cause, brought about by the same exposure as in the two cases described above.

The character of most of the operations done can not be said to be of the greatest danger, but the large majority would be placed in the class of major operations. I shall enumerate only those above 50 years of age, as we propose to study the influence of surgery on the aged. They are as follows: hemorrhoids, clamp and cautery, 26 cases; modified Whitehead, 8; inguinal hernia, 30 cases, ventral 1, femoral 1, umbilical 2; varicose veins, radical operation, 26; skin grafting, 1; tenotomy, 2; stricture of rectum, 2; resection of bowel, 2; fistula in ano, 9; prolapse of rectum, 2; prolapse of uterus, 2; hysterectomy for cancer, 1; hydrocele, 3; Tumors, removed, benign, 1; stricture of urethra, 3; resection of urethra, 1; ischio-rectal abscess, 2; perineal section, 2; circumcision, 1; varicocele, 1; Bottini operation for enlarged prostate, 6; appendicitis, 2; total, 131. Anesthesias: ether, 83; chloroform, 13; cocain, 30; total, 126.

---

* *Presented to the Section on Surgery and Anatomy, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.*

[1] This paper was written eighteen months ago, the cases here referred to all occurring in the years 1898-99. Since September, 1899, the number *has been materially* increased—the only death occurring in case of amputation of leg for sepsis due to senile gangrene.

Old people generally fear the anesthesia more than the operation, and it is interesting to observe that of the 217 cases recorded no patient has died or suffered materially from ether, chloroform or cocain. Ether was used 83 times, chloroform 13 and cocain 30 times in the elderly class.

To any one who has ever visited our almshouse and workhouse, it will be unnecessary to say that these cases were not particularly favorable ones for operation. They were not of the robust, well-nourished class, but rather the opposite. Neither were they carefully selected from such material as existed there. Our young house surgeons, in their enthusiasm to gain experience, have persuaded almost every one they found with surgical deformities or diseases to come into the hospital and undergo operation, and I must confess that I have rather tempted Providence sometimes, in operating on the cases presented, simply to encourage the staff in hunting up material, and because the patient wanted the operation. There were 30 cocain operations, 25 of them for varicose veins, from which all recovered with cure or great relief, and without suppuration; 1 clamp and cautery operation for hemorrhoids, 3 for small tumors, and 1 tenotomy, all of which made good recovery. There were 30 inguinal, 2 umbilical, 1 ventral and 3 femoral hernias, making 34 cases, in all of which the peritoneal cavity was invaded. Among these were only 2 cases in which there was a particle of pus. One of these two tore his bandages off during the first night after operation, thus causing an invasion of the superficial wound, which happily amounted to nothing, and the patient made a good recovery. In the other, done by my house surgeon, the bladder was cut, and the urine allowed to escape into the wound, which became infected. The patient recovered in due time, but, as was to be expected, the hernia returned, which, by the way, is the only case of recurrence in five years' experience with the modified operation for this deformity.

The 3 deaths in the elderly class were, unfortunately, all under this hernia class; only 1, however, should be charged to the operation. There were 35 operations for hemorrhoids, 26 by the clamp and cautery method, and 8 by the modified Whitehead operation. All of these recovered without incontinence or prolapse or other inconvenience. In the 9 operations for rectal fistula, there were 8 cures and 1 patient left before we could say what the result was. These cases were all stubborn and slow to heal. The remaining may be read from the list above. I will only call attention to the 2 cases of appendicitis, in both of which the appendix was removed, with the most gratifying results, and the 2 of resection of the intestines, both of these patients being about 70 years of age, and in one I removed over 21 inches of the small intestine, with the most perfect success. All of these were done under general anesthesia, chiefly ether, and the patients made good recoveries.

The mortality, as will be seen, is less than 3 per cent.; 1 per cent., in fact, if we exclude the unavoidable deaths from pneumonia. Albumin in the urine in small quantities has not been taken as a contraindication to operation, but those with fatty or epithelial casts have been rejected. Hyaline casts are not so serious, as they frequently occur in old people without any particular significance. Fatty, flabby old people have not been considered fit subjects for operation, but several have been done with good results. Operations requiring healing by granulations or long suppurative processes have not been considered satisfactory.

Time has always been considered an essential element of success, and the utmost celerity consistent with good work has been practiced. I do not believe that it is a matter of indifference whether the patient is kept under ether twenty minutes or an hour. Every minute that can be saved without prejudice to the operation is just so much gained, and lessens by just so much the danger of shock.

Whether this experience is better or worse than that of others in the same line of work I am not able to say, but certainly it does not sustain the general fear of operations in the aged. I have studied to find, if possible, some reason for the low mortality among these paupers, criminals and vagrants, but without any very definite conclusions. I have thought that perhaps age and hardship have inured them to privation and rendered them insusceptible to shock in a degree that we would not find in the higher walks of life. Certainly shock, which is so much dreaded by the general surgeons, has been almost absent in the large number on whom we have operated. But perhaps the more rational view to take of this is that when an individual has reached the age of 60 or 70 years, in comparative good health, we must assume that he has either taken good care of himself and not undermined his constitution by dissipation and excesses, or that he originally had an exceedingly strong constitutional foundation to build on, and thus presents himself a suitable subject for operation.

DISCUSSION.

Dr. R. H. Dawbarn, New York City—It has so chanced that I have had a great deal of work in this special line while acting for many years as attending surgeon to the Chapin Home for Old People, in New York City, and I have found that they bear operation much better than I should have supposed. The all-important thing is the avoidance of microbic infection as to whether we get almost as good results in old people as we do in younger patients. I have seen case after case heal aseptically and do remarkably well. On the other hand, persons having broken-down constitutions, living in public hospitals, or people advanced in age, lack the vital resistance which is necessary to oppose microbic invasion, and should this occur, you get bad results. An elderly man can not fight against a suppurative process like a young one.

Dr. Hart, China—I have operated many times for different diseases in old men, and very well remember one case of a man who had had a depression of the frontal bone for ten years. He had been struck by his brother in a fight at the age of 55 and came to me at 65. The depression was half an inch deep and I operated on him to remove three depressed fragments in the frontal bone. The patient made a splendid recovery and there has been no recurrence of the epileptic attacks from which he previously suffered. A number of men at the age of 75 have come to us and stood operation without any shock whatever. The middle class of Chinese stand operation well, but members of the upper do not, and this is probably due to their mode of living. Rice and meat are the principal articles of diet for the poor. Another class of cases occurring in the aged are those that suffer with epithelioma, but I find they all recover very readily without suffering from shock. Talking about old men in China, a man 75 there is practically where a man of 95 is here. A large number of the population die before 60, and a man of 70 is a rarity. I have operated on a man at the age of 90 who recovered without shock, his desire for operation being due to his wish that he could live to the age of 100, and thus get a special honor from the emperor. I told him I could not guarantee this, but the operation was performed some years ago and he is still living and looks well. I am sure the diet has a great deal to do with the patient's' ability to stand shock, and the surroundings and occupation also have their share of influence upon operations.

Dr. J. P. Tuttle, in closing, said the point brought out by Dr. Dawbarn in reference to the inability of old people to stand suppuration is brought out in his paper, but was not read. In every suppurative case the healing was prolonged and difficult. We get just as good results in aseptic cases in old men as in young, but not in the suppurative cases.

SARCOMA OF THE INTESTINES, WITH TABLE OF FIFTEEN CASES OF RESECTION.*

C. VAN ZWALENBURG, M.D.
RIVERSIDE, CAL.

Very little has been written on sarcoma of the intestines and many errors have crept into its consideration. Conclusions have been drawn from its supposed analogy to carcinoma of the intestines which the facts do not warrant. Prominent among these errors are: the accepted opinions as to the most common locations of the tumor, the early involvement of neighboring organs and the liability to produce obstruction. Few of our text-books on surgery refer to the subject.

The "International Text-Book of Surgery" (1900) says: "It may occur in any portion of the intestine—the cecum seems to be a favorite spot and several resections of this portion have been successfully performed for sarcoma."[1]

The "American Text-book of Surgery"[2] says that as sarcoma of the intestines usually gives rise to symptoms, of obstruction, and consequently comes under surgical treatment usually after extensive infiltration, it is questionable if it is prudent to attempt a radical operation as an early recurrence is almost inevitable. It suggests an intestinal anastomosis to exclude such obstruction should it occur.

Senn, in his text-book on tumors[3] (1900), as well as in his earlier "Intestinal Obstruction,"[4] puts it most frequently in the upper part of the small intestines, about the ileocecal region, the colon and the rectum. He says it usually comes to the surgeon after it has caused an obstruction. If in operating for an obstruction a sarcoma is found as its cause, an enterectomy is indicated if the tumor has not extended beyond the intestinal wall. If it has so extended he advises an artificial anus or, better still, an intestinal anastomosis.

Although a comparatively rare disease, it is much more rare in literature than in reality and deserves more attention. Of all the cases presented in the clinics during my medical course, one of the most deeply impressed on my memory was that of a young man summarily dismissed by Professor Maclean with the explanation that he had an abdominal tumor, undoubtedly sarcoma; that it would soon prove fatal, and that nothing could be done. The pale face of that patient has remained indelibly impressed on my memory. I find that a similar impression of the possibility of the disease together with its hopeless prognosis, is very prevalent among medical men. They all speak of personal acquaintance with sarcoma of the abdomen. How many of these cases are sarcoma of the intestine?

STATISTICS OF THE DISEASE.

F. Smoler,[5] analyzing 13,036 autopsies held at Professor Chiari's pathologic-anatomic institute of the German University, at Prague, found primary sarcoma of the intestine 13 times—1 in 1000. These occurred in fifteen years, 1883-1898. It occurred 7 times in the ileum—twice including the ileocecal valve—3 times in the jejunum and ileum and twice in the cecum. In the other case it occurred in the lower ileum and was associated with an adenocarcinoma of the pylorus in a woman 70 years old. Ten were males, 3 females; 5 times the patient's age was between 30 and 40, 4 times between 20 and 30, twice between 10 and 20, and twice over 40. Probably there were few children in the 13,000 autopsies. In 7 cases there was dilatation of the diseased gut, in 4 contraction, and in 4 there was no change in the lumen.

N. Moore[6] reported 2 cases of sarcoma in 26 of new growths in the alimentary canal. Both were males, one 25, the other 40 years old; 1 involved the descending colon, the other the descending colon and the ileum.

There is a single specimen in the U. S. Army Medical Museum. It was contributed by Dr. J. N. Yarnall, Washington, D. C. It is a portion of the ileum of a male 5 years old. It involved the entire circumference of the bowel. There was some narrowing of the canal, somewhat dilated above. Dr. E. Libman, pathologist for Mt. Sinai Hospital, New York City, recently read an exhaustive paper on this subject before the New York Pathological Society, and published in the *American Journal of the Medical Sciences* for September, 1900. He reported five cases which have occurred in this institution.

R. F. Weir[7] tabulating all resections of the intestines for malignant growth up to 1886, reports two cases of sarcoma out of a total of 35.

REPORT OF CASE.

Before considering the surgery for intestinal sarcoma, I will report a case which occurred in my practice at Kalamazoo, Mich., in the fall of 1899. In criticizing the report of my case I ask that it be remembered that it was done in a small private house with only a forlorn hope of life being prolonged.

The patient was Harold S., aged 5 years. His mother's mother died at an advanced age from carcinoma of the uterus; his father's mother of carcinoma of the stomach. About June 1, 1899, the child fell from a fence and was caught between two boards and held hanging on the abdomen, head down, for some minutes. The injury was considered trifling at the time and no physician was called. About the middle of June he began to complain of abdominal pain, had repeated attacks of vomiting, his appetite left him, and he began a steady decline without any appparent cause except the general symptoms of indigestion. About the middle of July, I discovered a nodule less than one inch in diameter, in the median line midway between the umbilicus and the ensiform cartilage. It was smooth, hard, round and freely movable over a radius of four or five inches. Its growth was very marked and by September 15, it was about the size of a hen's egg. It then became fixed in the left hypochondriac region so as to produce by position an obstruction of the bowels with great pain. By careful manipulation and placing the patient upon the right side, I succeeded in moving the tumor from its fixed position and the obstruction disappeared. The diagnosis was an abdominal growth, probably omental and probably sarcomatous. A very grave prognosis was given. The tumor had all along been freely movable and an exploratory operation was advised in the hope that the growth—of whatever character—might possibly be so situated that it could be successfully removed. The operation was at first declined, but in November the parents finally decided to have it done, provided it might be performed "at home." It had been so long delayed that it was undertaken with the expectation of finding so much adhesion and involvement of important structures that removal would be out of the question. The patient was by this time very anemic, emaciated and feeble. He could scarcely walk. His temperature was 100 F. and pulse 120, soft and feeble.

Operation.—At 10:30 a.m., Nov. 18, 1899, the abdomen was opened in the median line above the umbilicus, the incision being four inches in length. The growth was lifted from its bed in the left hypochondrium, and out of the abdomen. The principal growth was irregularly oblong, about four inches in length and three in width, and consisted of a contracted thickened mass with a partial intussusception of the ileum into the colon, drawing the healthy appendix with it. Bringing out more of the ileum, a secondary growth was exposed about two inches in diameter, which had been felt in the right iliac fossa. About three inches of fairly healthy intestine connected the two principal growths. The mesentery and mesocolon were long, allowing of easy manipulations. Several of the mesenteric glands were involved in secondary growths.

---

* Presented to the Section on Surgery and Anatomy, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Notwithstanding the extended involvement, it was decided to remove the growth with all the mesenteric glands as the only possible hope of prolonging the boy's life. This was done by making an exsection of the ascending colon, together with six or seven inches of the ileum and all the mesenteric glands involved, making an end-to-end anastomosis with the Murphy button. The abdominal wound was closed, leaving a narrow strip of gauze running down to each side of the line of anastomosis. This was considered advisable on account of being obliged to operate in a small private house where we could not be assured of thorough asepsis.

The patient received two hypodermic injections of strychnin, 1/60 gr. each, during the operation, and immediately after its completion he was given 8 oz. of normal salt solution per rectum and the same amount in the subcutaneous tissues of the chest. He suffered much less from shock than was anticipated. About three hours after being placed in bed, the father—who was chief nurse—stepped out of the room for a moment and upon his return found him sitting up in bed. After twenty-four hours his condition was comparatively good, pulse 130, temperature normal, with no vomiting. Gas had passed the bowel. He continued to improve steadily. His highest temperature noted was 100 F., about the eighth day. His bowels moved on the fourth day. The gauze was removed from the wound on the fourth day. The serum which followed it had a slightly fecal odor. By the end of the first week a decided fistula had developed. This did not retard the recovery and closed spontaneously within four weeks of the operation. He was out of bed in three weeks and walked after five weeks. The button was passed on May 11, 1900, six months after the operation. The patient continues well and, six months after the operation, weighs 50 pounds, 17 more than before operation.

Microscopic Examination.—Drs. G. F. Inch and F. E. Allen, of the Michigan Asylum for the Insane, at Kalamazoo, made the microscopic examination of the tumor and pronounced it undoubtedly a small, round-celled sarcoma. Microscopic sections were also examined by Drs. A. C. Crofton, of Pasadena, and Stanley P. Black, of Los Angeles, with the same conclusions. The following is Dr. Allen's report:

The gross specimen, consisting of six or seven inches of small intestine above the ileocecal valve, the same amount of large intestine, the vermiform appendix and several enlarged mesenteric glands was received in Müller's fluid, from which it was removed, washed in water and placed in alcohol—80 per cent.

The large intestine had been cut lengthwise, disclosing the tumor and the latter cut across. The tumor was a firm mass about the size of a hen's egg, surrounding the ileocecal valve like a ring, the greater part lying to one side, a depression in the surface corresponding to the opening into the small intestine. This opening easily admitted the forefinger. The tumor projected into the lumen of the large intestine, was covered with the intestinal mucosa and attached by a broad base to the bowel wall. The cut surface was white and glistening and yielded, on scraping, a milky fluid. The appendix was apparently normal. In the fat of the mesentery near the junction of the large and small intestines were several mesenteric glands, some of them somewhat enlarged. Four or five inches from the ileocecal valve, on the small intestine, was a second tumor nearly as large as the other. It was not connected with the lumen of the bowel, nor did it project into it, but in close apposition to the intestine between the two layers of the mesentery. On cross-section it resembled the large tumor in structure.

On account of the size and the fact that the tumor had taken the place of the bowel wall, the large growth was evidently the primary tumor, and the growth on the small intestine a secondary in a mesenteric gland. Portions were taken from the primary tumor, the secondary and from one of the smaller mesenteric glands, fixed in alcohol, imbedded in paraffin and stained with hemotoxylin and Van Giesen's method.

Primary Tumor: Sections were taken from the periphery of the tumor. The mass of the structure was made up of small round cells with deeply staining nuclei; there was a fine delicate reticulum, composed in some parts of branching and anastomosing connective-tissue cells, and the reticulum could everywhere be seen lying between and separating the tumor cells. There were not a great many blood-vessels, but those present had very thin walls and in some cases the cells themselves formed the walls. At one side of the section was seen the mucosa with its gland ducts cut transversely and its underlying muscularis mucosa. All throughout the mucosa are seen these small cells which surround the glands, even penetrating between the columnar cells lining the ducts. The muscularis mucosa is in some places almost obliterated by the pushing in of the cells between its unstriped fibers. The submucosa has disappeared, as has also the muscle coats of the bowel, and their place is taken by the tumor structure. At one side of the section may be seen a few muscle fibers, probably those belonging to the muscular coats which are infiltrated and separated by the tumor cells.

Secondary: This section shows practically the same tumor structure, but the normal relation of the coats of the small intestines is better preserved. The intestinal wall is seen with its mucosa, submucosa and muscular coats, but the tumor cells are found between the muscle fibers and have penetrated even as far as the mucosa.

There are two modes of origin possible for the growth of the primary tumor: 1. It may have arisen in a mesenteric gland, causing its enlargement until it reached the bowel wall which it soon infiltrated and disintegrated. 2. It may have arisen from a solitary lymph follicle in the large intestine, and this latter view is the more acceptable, as it is the common mode of origin for sarcoma of the intestine.

Again, *a*, from the nature of the cell, a small round one with a nucleus staining so deeply and occupying so much of the cell that it requires careful focusing to make out the ring of protoplasm about it; *b*, from the nature of the reticulum a fine branching vascular connective-tissue stroma; *c*, from the nature of the relation of the reticulum to the cells lying always between and about them, and *d*, from the nature of the relation of the cells to the blood-vessels, forming in some cases their walls, it is evident that the tumor belongs to that class of small round-cell sarcomata known as lymphosarcoma, since it reproduces to a certain extent the normal histology of a lymph gland.

TABLE OF CASES OF RESECTION.

After a careful search in the library of the New York Academy of Medicine, I am able to present the accompanying table of cases of resection for sarcoma of the intestine.

Of the fifteen cases, 9 were males and 5 females. The youngest was 1½ years old, the oldest 52; 5 were under 10 years, 1 between 10 and 20, and 2 between 20 and 30; 1 was 30, and 5 between 40 and 50. The small intestine was alone involved 10 times; both small and large intestines twice; the cecum once; the transverse colon once. The Murphy button was used in 4 instances. Of the 15 patients, 9 recovered from the effects of the operation. The cause of death in the 6 fatal cases is put down as peritonitis twice; sepsis and pneumonia, 1 case; collapse, 1; not stated, 2 cases. Of the children under 10, only 1 succumbed to the operation. This was a boy of 8, from whom 52 cm.—21 inches—of ileum and cecum had been removed. All the other deaths occurred in patients over 40, except possibly 1, whose age is not given. In none of these cases is it positively stated that the correct diagnosis was made before operating. Usually it is put down as obscure. Once only was it done for obstruction. Of those who survived the operation, 1 died after three weeks, another in two months, from widespread metastasis. Two were well one year after operation; 1 is well six months after. Mesenteric glands were reported involved in 4 of the patients who recovered. In addition to these I found 2 cases recorded of exploratory opening of the abdomen, in which, on account of the widespread extension of the disease, no resection was done: 1 by Professor Madelung,[8] another by Tschermakowski.[9] Death followed in a few days in both cases.

Once suspected, no time should be lost in waiting for the diagnosis to be cleared up. The time for hesitating to do an exploratory laparotomy is past, especially in the face of so fatal a disease as sarcoma. There has been so much advance in intestinal surgery of late that every patient of this kind should have the benefit of that possibility of relief. Professor Kukula[10] has recently tabulated 31 cases of resection of more than 1 meter of small intestine, and has demonstrated that there is practically no limit to the amount of intestine that can be safely removed. In one patient only two-fifths of the small intestine was left. As only 3 of these 31 patients died from collapse, there is evidently not so much shock from these operations as the first attempts at resection seemed to indicate.

14	Weir, R. F., New York City.	1900	M.	45	8 in. jejunum.	End-to-end; Murphy button.	Died after 11 days; sepsis and pneu*monia.*	Sarcoma	Diag. obscure from enormous intermittent distention of *stomach* and bowel above tumor stenosis.	Oral communnication to writer.
15	Van Zwalenburg, Kalamazoo, Mich.	1899	M.	5	18 in. ileum and colon.	Murphy button.	Recovered; well after six months.	Small round-cell lymphosarcoma.	Exploratory operation; m. glands removed.	. . . .

From a study of these cases I am led to the following conclusions: Sarcoma of the intestine is more common than our text-books indicate. It much more frequently affects the small than the large intestine. The ileum seems to be its favorite location. Sarcoma rarely produces stenosis. Dilatation is more frequent. Usually it grows from one side of the bowel entirely. In my own case the symptoms of obstruction were evidently due to a change in position of the freely movable tumor. It was entirely relieved by manipulation. The diagnosis is difficult and will always remain obscure, still if a smooth freely movable tumor be found in the abdomen, unless it can be otherwise satisfactorily accounted for, we should be reminded of the probability of *sarcoma of* the intestine—especially if there is also present the general picture of sarcoma with its peculiar anemia.

We are learning that many of the cases of so-called collapse *and death* from shock are after all cases of sepsis. Sepsis following an operation is a question of technic and should not stand in the way of a good result here. The children in my table bore this operation well; only one of the five succumbed to the procedure. The way my patient went through it was a constant revelation to all who knew the circumstances.

In the present state of our knowledge of sarcoma it almost goes without saying that the only treatment for the intestinal form is resection. When an exploratory opening is made and a well-advanced sarcoma is found, exsection at great hazard is justifiable, not only on account of the absolutely bad diagnosis of the disease itself, but also because of the dangers of sepsis in the presence of tissues of such low vitality and of the dissemination of sarcoma foci by the exploration. The two reported cases of this kind terminated fatally in a very few days. In this connection we have a right to assume that in extirpating a sarcoma we remove a toxin center as truly as when we open an abscess.

REST TREATMENT FOR HYSTERICAL DISEASE.*

JOHN K. MITCHELL, M.D.
PHILADELPHIA.

Indications and Technique.—Hysteria is a term which I once regarded as a vague excuse for a diagnosis, but for the last six or seven years it has been, I think, somewhat displaced from this proud position of general scapegoat by the word neurasthenia. What are the symptoms which indicate that a hysterical case is one for the rest-treatment? When we find a case in which there is great nervous instability combined with physical weakness, and usually with absence of distinct organic disease, especially if there are present some or all of the moral defects which so commonly accompany pronounced hysterical disease, then we have a symptom-complex calling for treatment by rest and isolation.

I need not dwell on the other hysterical stigmata; the list is a long and varying one, although the more essential points are well known and fairly common: backache, headache, insomnia, constant fatigue, are signs not peculiar to hysteria, but when we add to these a tender spine, tender ovaries, vague wandering pains with no discoverable substantial reason for their existence, intense interest in the varying symptoms presented, disturbances of sensibility, perhaps paralysis or contractures, above all if the symptoms are too numerous or too variable we may without hesitation call the case a hysterical one.

Certain forms of acute disease, especially uterine or periuterine, are almost the only contraindications to the treatment of such cases by rest, if we set aside the cases with distinct organic disease of the lungs or kidneys.

I may repeat what has so often been insisted on: The worse the case the more satisfactory is the treatment, as a rule. An emaciated, half-blind, anemic girl, who eats nothing and keeps herself shut in a dark room, where to a sympathetic selection of relatives she plays her hysterical comedy, sometimes to a tragic conclusion, is the kind which gives the best promise of a highly successful result.

Taking such a typical case, when, where and how shall it be treated? As to the time to begin treatment, the sooner the better is a good rule, and the only thing which would fix any special time is that immediately after the menstrual period is usually the most suitable moment for commencement. My own experience is in favor of treatment in a private house rather than in an institution. A private room in a good hospital, if the patient can have a personal nurse, will serve. As a rule such cases do not do as well if they depend on the hospital staff for nursing. One takes too many chances in the daily or hourly change of nurses and the unoccupied time for brooding is too great. In a hospital ward the matter of isolation is especially difficult to manage, and I do not like sanitaria or such institutions, chiefly for the reason that they add a new difficulty to the management of convalescents unless isolation can be thoroughly maintained to the end of the treatment. The herding together of partially recovered patients in large rooms and meeting-places usually results in the swapping of symptoms, in comparison of the virtues or vices of the respective nurses, and in consequent general dissatisfaction. A proper room in a proper place having been secured, it may be added that light, sunshine and ventilation are naturally of high importance.

Nurse.—My rule is never to use the nurse who comes with the patient from home. When in exceptional instances I find it necessary, or yield to the importunities of the patient or relations to do so, sooner or later I find cause to regret it. The same rule applies to relatives, and generally against nurses with whom the patient has a previous acquaintance. Enthusiasm controlled by educated intelligence is the first requisite. As a rule this is found in its best forms in young nurses. This matter of the choice of a nurse can not be too much insisted on; scarcely any other single element is so vital. I prefer to have a nurse who is agreeable to the patient, but this is not always necessary, and if the patient finds that she can get a change of nurses because she says she does not like the nurse, she will sometimes go on changing indefinitely in the hope that she may discover one more amenable to her ways of thinking. Still I never hesitate to change the nurse if the patient has a reasonable objection to offer, since even the best nurses do not suit every patient.

Among the strictest orders which I give the nurse are that neither the symptoms she may observe, the difficulties of management she encounters nor questions of treatment are ever to be talked over with or before the patient. She reports to the physician when he enters the room, waits a few minutes to see if he has any questions to ask, submits her daily notes, and without further words retires outside to wait for orders. This gives the patient freedom to speak about her nurse should she wish to do so, and to express, as she should freely do, her own views about herself. If the patient does not do well and no clear reason can be given for it, if the digestion is good, and yet somehow the case seems to be at a standstill, then it is best to try a new nurse. It is well to keep a judicial attitude of mind and certainly never permit oneself to fancy that all the difficulties which may arise are the patient's fault. Sometimes patient and nurse do not get on from some trifling defect of manner or method in the nurse which, if not susceptible to correction, is best met by replacing her with another nurse. The matter may be summed up by saying that all the qualities which a good nurse should have are required in their highest degree in a nurse for hysterical patients, and, in addition to these, the nurse must have certain personal accomplishments, such as being able to read aloud, which are not a necessary part of the ordinary nurse's education.

* Presented to the Section on Nervous and Mental Diseases, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Isolation.—Isolation I regard as the most important feature of the treatment. Once in a while, though less often than formerly, I consent to treat patients in their own homes. Even in the largest and best managed households this is usually only a way of greatly increasing the physician's annoyances and responsibilities and delaying the progress of the cure. Isolation can seldom be complete when the patient knows that only a door or a partition separates her from the members of her family. Difficulties, too, are not always from the patient's side. In fact one experiences less difficulty with the patient than with her friends and relations. Then, too, the mere fact of being in an entirely new place contributes to that change of moral atmosphere which it is so desirable to bring about, and if the change of place and surroundings is a little less comfortable for the patient, that, properly viewed, is only an added incentive to rapid recovery. The more distinctly hysterical the disease is, the more strict the isolation must be. No letters are sent or received, no visitors are seen, and but three or four persons enter the room, the nurse, the physician, the masseuse and the servant. As I have said elsewhere, there is another reason why this seclusion is useful: it enables one to gauge the amount of the emotional element in the case, to see how far emotional disturbances are due to the patient's own disposition and how far they are caused or increased by her surroundings. When these cases are treated in a hospital room, it is well to direct that the resident physician should pay but one visit a day in order, as far as possible, to limit the audience before which the comedy is performed.

As to the period during which isolation must last, this is a matter to be judged by the attainment of the desired results, not by the calendar. In ordinary cases of moderate degree six or eight weeks of absolute isolation is generally long enough and at the end of the time one may admit a single visitor, to observe the effect upon the patient, afterward gradually allowing the return to more ordinary methods of life. In the more serious cases, especially those of simulated disease or with grave hysterical symptoms, many months of isolation may be necessary and a life of careful and methodical regulation must be continued long after almost all symptoms have disappeared if the inveterate hysteric is not to relapse. Toward the end a limited number of letters are permitted and, by way of reward for good conduct, the patient may write briefly once or twice a week to some one member of her family. If so long a period of separation from home, friends, and domestic surroundings sounds like a severe measure, it should be remembered that what has to be accomplished is the breaking up radically of the habits of long invalidism.

Rest.—Rest, like isolation, is often badly borne during the early days of treatment, but the complaints which it causes, if met with patience and reasonable firmness, usually disappear within a week and the patient settles down, not merely with resignation, but often with satisfaction, to a life which may be described as one of almost complete physical immobility. At first in serious cases it is often well to have the patient fed by the nurse; in this way food will usually be taken in much larger quantities than if the patient serves herself. Ordinarily one hardly carries the prescription to this extremity, the patient feeding herself, but not sitting up further, except for emptying the bowels, etc. Thus, the use of the voluntary muscles is kept at the lowest possible point; the isolation, the absence of letters or any other cause of excitement keeps the mind inactive; the physical stillness lessens the excitability of the circulation which is usually present, and one result soon seen is an improvement in the ability to sleep.

Diet.—If indigestion, loss of appetite, or obvious gastro-intestinal feebleness is present, then milk diet makes a good starting-point. Here one often runs against an obstacle. Many patients will say that they can not take milk, and if it is given in ordinary quantities and in the ordinary way, they are very likely unable to digest it. Still it is rare to find that with care and a little ingenuity, milk can not be used. What is true of milk when used with other food is not true of milk when it is the exclusive diet. It is often necessary to begin with very small amounts. An ounce or two ounces every two or three hours, increased little by little while the other food is decreased, will generally be well borne. In a few days, with the increase of the milk, solid food may be withdrawn. Skimmed milk can nearly always be taken by patients who have indigestion from whole milk, and skimmed milk contains the most essential food values, only the fat having been removed by the process of skimming. When milk diet is not necessary the patient is ordered to begin with the usual three meals. No stress is laid on the taking of food in large quantities during the first few days; dependence is placed on the improvement of appetite, which comes with the quiet and the stimulation of desire for food by massage, as well as the increased ability to take it, which results from this form of exercise. If long continuance of milk diet is not considered necessary, after four or five days of milk alone, a chop or a piece of steak is given at midday, in addition to the milk. The next day, bread and butter or an egg is added at the second meal, and the increase is kept up by similar advances until the patient takes three full meals and from 50 to 60 ounces of milk a day. Where milk is badly borne, some other form of light and digestible food may be substituted, or broths, meat-jellies, etc., used to vary the diet.

Massage.—The profession is a little better informed about massage than formerly. Still something remains for most practitioners to learn as to the best methods and the ways of using it. It is preferable, as a rule, to have some other person than a nurse to do the rubbing, as in serious cases the nurse will have quite enough work, and the hour of massage followed by an hour of rest serves well for a period of escape for the nurse. Massage may be prescribed after the patient has had one or two days' rest in bed, beginning with light treatment not lasting over fifteen or twenty minutes and increasing in two or three days to thorough deep massage of the whole surface of the body and limbs, a process which should last for at least an hour daily in persons of ordinary size. In thin or small patients less time may serve; in the obese a longer duration of the rubbing will be necessary. A second rubbing by the nurse, not quite so thorough, with special attention to the abdomen and the spine may be given at night, some patients finding this a great help to quiet sleep. As to how the physician, who is ignorant of the methods of massage, is to know whether his patient is being properly rubbed, this practical hint may not be out of place. If after a week of massage, the patient does not take with ease the amount of food prescribed and thoroughly digest it, the massage is insufficient in quantity or bad in quality, and a change either in the plan of rubbing or in the person administering it is called for. Also, while a steady increase in weight may be expected after the first week, if the patient's weight increases too fast, the massage is either not producing sufficient tissue semination of sarcoma foci by the exploration. The two reported cases of this kind terminated fatally in a very few days. In this connection we have a right to assume that in extirpating a sarcoma we remove a toxin center as truly as when we open an abscess.

REST TREATMENT FOR HYSTERICAL DISEASE.*

JOHN K. MITCHELL, M.D.
PHILADELPHIA.

Indications and Technique.—Hysteria is a term which I once regarded as a vague excuse for a diagnosis, but for the last six or seven years it has been, I think, somewhat displaced from this proud position of general scapegoat by the word neurasthenia. What are the symptoms which indicate that a hysterical case is one for the rest-treatment? When we find a case in which there is great nervous instability combined with physical weakness, and usually with absence of distinct organic disease, especially if there are present some or all of the moral defects which so commonly accompany pronounced hysterical disease, then we have a symptom-complex calling for treatment by rest and isolation.

I need not dwell on the other hysterical stigmata; the list is a long and varying one, although the more essential points are well known and fairly common: backache, headache, insomnia, constant fatigue, are signs not peculiar to hysteria, but when we add to these a tender spine, tender ovaries, vague wandering pains with no discoverable substantial reason for their existence, intense interest in the varying symptoms presented, disturbances of sensibility, perhaps paralysis or contractures, above all if the symptoms are too numerous or too variable we may without hesitation call the case a hysterical one.

Certain forms of acute disease, especially uterine or periuterine, are almost the only contraindications to the treatment of such cases by rest, if we set aside the cases with distinct organic disease of the lungs or kidneys.

I may repeat what has so often been insisted on: The worse the case the more satisfactory is the treatment, as a rule. An emaciated, half-blind, anemic girl, who eats nothing and keeps herself shut in a dark room, where to a sympathetic selection of relatives she plays her hysterical comedy, sometimes to a tragic conclusion, is the kind which gives the best promise of a highly successful result.

Taking such a typical case, when, where and how shall it be treated? As to the time to begin treatment, the sooner the better is a good rule, and the only thing which would fix any special time is that immediately after the menstrual period is usually the most suitable moment for commencement. My own experience is in favor of treatment in a private house rather than in an institution. A private room in a good hospital, if the patient can have a personal nurse, will serve. As a rule such cases do not do as well if they depend on the hospital staff for nursing. One takes too many chances in the daily or hourly change of nurses and the unoccupied time for brooding is too great. In a hospital ward the matter of isolation is especially difficult to manage, and I do not like sanitaria or such institutions, chiefly for the reason that they add a new difficulty to the management of convalescents unless isolation can be thoroughly maintained to the end of the treatment. The herding together of partially recovered patients in large rooms and meeting-places usually results in the swapping of symptoms, in comparison of the virtues or vices of the respective nurses, and in consequent general dissatisfaction. A proper room in a proper place having been secured, it may be added that light, sunshine and ventilation are naturally of high importance.

Nurse.—My rule is never to use the nurse who comes with the patient from home. When in exceptional instances I find it necessary, or yield to the importunities of the patient or relations to do so, sooner or later I find cause to regret it. The same rule applies to relatives, and generally against nurses with whom the patient has a previous acquaintance. Enthusiasm controlled by educated intelligence is the first requisite. As a rule this is found in its best forms in young nurses. This matter of the choice of a nurse can not be too much insisted on; scarcely any other single element is so vital. I prefer to have a nurse who is agreeable to the patient, but this is not always necessary, and if the patient finds that she can get a change of nurses because she says she does not like the nurse, she will sometimes go on changing indefinitely in the hope that she may discover one more amenable to her ways of thinking. Still I never hesitate to change the nurse if the patient has a reasonable objection to offer, since even the best nurses do not suit every patient.

Among the strictest orders which I give the nurse are that neither the symptoms she may observe, the difficulties of management she encounters nor questions of treatment are ever to be talked over with or before the patient. She reports to the physician when he enters the room, waits a few minutes to see if he has any questions to ask, submits her daily notes, and without further words retires outside to wait for orders. This gives the patient freedom to speak about her nurse should she wish to do so, and to express, as she should freely do, her own views about herself. If the patient does not do well and no clear reason can be given for it, if the digestion is good, and yet somehow the case seems to be at a standstill, then it is best to try a new nurse. It is well to keep a judicial attitude of mind and certainly never permit oneself to fancy that all the difficulties which may arise are the patient's fault. Sometimes patient and nurse do not get on from some trifling defect of manner or method in the nurse which, if not susceptible to correction, is best met by replacing her with another nurse. The matter may be summed up by saying that all the qualities which a good nurse should have are required in their highest degree in a nurse for hysterical patients, and, in addition to these, the nurse must have certain personal accomplishments, such as being able to read aloud, which are not a necessary part of the ordinary nurse's education.

Isolation.—Isolation I regard as the most important feature of the treatment. Once in a while, though less often than formerly, I consent to treat patients in their own homes. Even in the largest and best managed households this is usually only a way of greatly increasing the physician's annoyances and responsibilities and delaying the progress of the cure. Isolation can seldom be complete when the patient knows that only a door or a partition separates her from the members of her family. Difficulties, too, are not always from the patient's side. In fact one experiences less difficulty with the patient than with her friends and relations. Then, too, the mere fact of being in an entirely new place contributes to that change of moral atmosphere which it is so desirable to bring about, and if the change of place and surroundings is a little less comfortable for the patient, that, properly viewed, is only an added incentive to rapid recovery. The more distinctly hysterical the disease is, the more strict the isolation must be. No letters are sent or received, no visitors are seen, and but three or four persons enter the room, the nurse, the physician, the masseuse and the servant. As I have said elsewhere, there is another reason why this seclusion is useful: it enables one to gauge the amount of the emotional element in the case, to see how far emotional disturbances are due to the patient's own disposition and how far they are caused or increased by her surroundings. When these cases are treated in a hospital room, it is well to direct that the resident physician should pay but one visit a day in order, as far as possible, to limit the audience before which the comedy is performed.

As to the period during which isolation must last, this is a matter to be judged by the attainment of the desired results, not by the calendar. In ordinary cases of moderate degree six or eight weeks of absolute isolation is generally long enough and at the end of the time one may admit a single visitor, to observe the effect upon the patient, afterward gradually allowing the return to more ordinary methods of life. In the more serious cases, especially those of simulated disease or with grave hysterical symptoms, many months of isolation may be necessary and a life of careful and methodical regulation must be continued long after almost all symptoms have disappeared if the inveterate hysteric is not to relapse. Toward the end a limited number of letters are permitted and, by way of reward for good conduct, the patient may write briefly once or twice a week to some one member of her family. If so long a period of separation from home, friends, and domestic surroundings sounds like a severe measure, it should be remembered that what has to be accomplished is the breaking up radically of the habits of long invalidism.

Rest.—Rest, like isolation, is often badly borne during the early days of treatment, but the complaints which it causes, if met with patience and reasonable firmness, usually disappear within a week and the patient settles down, not merely with resignation, but often with satisfaction, to a life which may be described as one of almost complete physical immobility. At first in serious cases it is often well to have the patient fed by the nurse; in this way food will usually be taken in much larger quantities than if the patient serves herself. Ordinarily one hardly carries the prescription to this extremity, the patient feeding herself, but not sitting up further, except for emptying the bowels, etc. Thus, the use of the voluntary muscles is kept at the lowest possible point; the isolation, the absence of letters or any other cause of excitement keeps the mind inactive; the physical stillness lessens the excitability of the circulation which is usually present, and one result soon seen is an improvement in the ability to sleep.

Diet.—If indigestion, loss of appetite, or obvious gastro-intestinal feebleness is present, then milk diet makes a good starting-point. Here one often runs against an obstacle. Many patients will say that they can not take milk, and if it is given in ordinary quantities and in the ordinary way, they are very likely unable to digest it. Still it is rare to find that with care and a little ingenuity, milk can not be used. What is true of milk when used with other food is not true of milk when it is the exclusive diet. It is often necessary to begin with very small amounts. An ounce or two ounces every two or three hours, increased little by little while the other food is decreased, will generally be well borne. In a few days, with the increase of the milk, solid food may be withdrawn. Skimmed milk can nearly always be taken by patients who have indigestion from whole milk, and skimmed milk contains the most essential food values, only the fat having been removed by the process of skimming. When milk diet is not necessary the patient is ordered to begin with the usual three meals. No stress is laid on the taking of food in large quantities during the first few days; dependence is placed on the improvement of appetite, which comes with the quiet and the stimulation of desire for food by massage, as well as the increased ability to take it, which results from this form of exercise. If long continuance of milk diet is not considered necessary, after four or five days of milk alone, a chop or a piece of steak is given at midday, in addition to the milk. The next day, bread and butter or an egg is added at the second meal, and the increase is kept up by similar advances until the patient takes three full meals and from 50 to 60 ounces of milk a day. Where milk is badly borne, some other form of light and digestible food may be substituted, or broths, meat-jellies, etc., used to vary the diet.

Massage.—The profession is a little better informed about massage than formerly. Still something remains for most practitioners to learn as to the best methods and the ways of using it. It is preferable, as a rule, to have some other person than a nurse to do the rubbing, as in serious cases the nurse will have quite enough work, and the hour of massage followed by an hour of rest serves well for a period of escape for the nurse. Massage may be prescribed after the patient has had one or two days' rest in bed, beginning with light treatment not lasting over fifteen or twenty minutes and increasing in two or three days to thorough deep massage of the whole surface of the body and limbs, a process which should last for at least an hour daily in persons of ordinary size. In thin or small patients less time may serve; in the obese a longer duration of the rubbing will be necessary. A second rubbing by the nurse, not quite so thorough, with special attention to the abdomen and the spine may be given at night, some patients finding this a great help to quiet sleep. As to how the physician, who is ignorant of the methods of massage, is to know whether his patient is being properly rubbed, this practical hint may not be out of place. If after a week of massage, the patient does not take with ease the amount of food prescribed and thoroughly digest it, the massage is insufficient in quantity or bad in quality, and a change either in the plan of rubbing or in the person administering it is called for. Also, while a steady increase in weight may be expected after the first week, if the patient's weight increases too fast, the massage is either not producing sufficient tissue waste, or the character of the food needs examination. It may be added as another practical point that the use of oil or other form of lubricant lessens very much the value of massage, as proper deep kneading can not be done when the surface is greasy and the lessening of the friction between the hand of the operator and the skin does away with one of the useful elements of the treatment. Lazy operators will, however, tell you they can not rub without oil. In that case, get another who is less afraid of work.

Electricity.—Of the original measures proposed for the combination which makes a complete rest treatment, electricity is perhaps the one which may with least disadvantage be omitted. Nevertheless I seldom omit it when the patient is on full treatment, if for no other reason than because it fills an hour or so of the day which might otherwise be unoccupied. There are only two forms which are commonly prescribed. The slowly interrupted faradic current is applied to the motor points all over the body, thus moving in turn every accessible muscle. The muscles should be contracted three or four times each and an appreciable amount of exercise as well as a very decided tonic influence is thus to be had. This will require in an ordinary-sized person half an hour, at most, if the operator knows the motor points. If the spine is tender the treatment is finished by passing a rapidly interrupted current from the nape of the neck to the soles of the feet, using a large electrode at the nape of the neck and another smaller one placed a few minutes on each foot. If constipation is troublesome, special applications may be made to the abdomen, using a rapidly interrupted current passed deeply from side to side and from the back to the anterior abdominal wall. Many patients are much afraid of the use of electricity from having been hurt by ignorant or careless methods. There is no reason why it should be painful if rightly used, and many nurses are well instructed in its ordinary applications. If the patient expresses alarm, and especially if she is of an apprehensive kind, it is best to begin the first day or two by making a dummy application, the battery working so that the patient can hear the sound, but the electrodes being used without connecting the wires to the battery. If this causes excitement or the patient complains of strange symptoms, continue the use in this fashion for two or three days, assuring the patient that she will not be hurt. If she still continues to fuss about it, after two or three days I tell them simply and plainly that they have fussed over the application of two damp sponges.

Special Difficulties.—In the course of treatment certain difficulties always arise. A bilious attack may be the not unnatural or unexpected accompaniment of the full feeding. Starvation in some degree, a laxative, or a return for a few days to a milk or skimmed milk diet, is sufficient treatment. Constipation, especially at the beginning of the course, may be annoying, but should not continue to be so if the massage is properly performed. Still in occasional cases, in spite of the most careful manipulation and electrical application, this may make trouble. Usually the ordinary aloin and strychnia-pill at night and morning will suffice to overcome. For very old inveterate cases, some more radical means must be used. Hot-oil injections, special manipulations of the abdomen, electrical applications per rectum are some of the means.

Insomnia is another frequent difficulty of the first nights of treatment and occasionally persists throughout the course. The use of drugs should be avoided as far as possible, as nothing can be steadily given without some ill effects on the circulation or blood-making functions or digestion. The drip-sheet, the wet pack, and the abdominal compress are among the hydrotherapeutic measures which may assist in overcoming sleeplessness. Massage at night as well as in the day time, applied somewhat less severely, will help many patients. The application of electricity to the spine as described is found sedative by others.

As to the question of moral control and the teaching of the patient to overcome for herself the habits, modes of thought, and ways of life which digged the pit for her to fall into, I despair of even suggesting them in the time at my disposal, but it can not be too strongly insisted on that anyone who attempts the cure of hysterical patients without the largest comprehension of the moral aspects of the treatment, without intense human sympathy and the power which imagination gives to put himself in the place of the sufferer, may perhaps be able to cure the bodily conditions, but will cure them only to send his patient out to relapse at the first opportunity. The treatment should include, as a recent patient described it to me, schooling in wisdom as well as in better physical methods of life.

I am told that one difficulty experienced by physicians in the effort to apply the rest treatment is in getting patients out of bed, and at a meeting of the ASSOCIATION this criticism was made a year or two ago, but, like the moral control, it is a matter which can scarcely be described exactly to any one else. I can only recall once in a good many years having had this trouble, and then it was with a hypochondriacal patient who expressed her preference for being pushed in a wheeled chair to walking. However, walk she did and was still walking when last heard from. Great care is needed in getting patients out of bed. A person whose circulation is regulated to the requirements of recumbency by six weeks of supine position can not be expected to suddenly begin sitting up without feeling faint, weak and fatigued in a very short time. My own rule is that the patient sits up in bed for ten minutes two or three times a day to begin with, that when this has been continued for two or three days the time is increased to fifteen minutes and then she is allowed to get out of bed, of course without dressing, and sit in a comfortable chair, carefully protected from cold, for twenty minutes twice a day with a distinct order to go back to bed before the expiration of that time if she feels fatigue. For a week before getting up, the masseuse is directed, after finishing her manipulations, to give passive movements of each extremity every day; after three or four applications the patient does the movements actively. In another day or two the nurse begins to steadily increase by five minutes every period of sitting-up. It will thus require about a week before she is up for more than forty minutes, but when she is up this long without inconvenience, I allow a few steps to be taken, not more, and at the end of ten days, or thereabouts, from first getting out of bed, she goes for a short drive, but is not allowed to walk up and down stairs to reach the carriage. If she is not in a place where there is an elevator she is carried. The same care is exercised about every little advance and increase in activity.

During this time of getting up the Swedish movements, which were begun before the patient got out of her bed, are continued and increased in number and variety, special exercises being given for the defective parts of the body.

I believe that the causes of failure with these patients lie more usually in neglect to perceive and allow for the moral conditions of the case than misunderstandings of the physical state. The after-care, the choice of the place in which the patient shall spend some weeks or months of the convalescent period, during which she should be making steady gain in nervous control as well as in physical force, must occupy the physician's attention. When it is possible, if the patient can not see the physician in person every week or fortnight, the nurse should either see him or report regularly to him in writing, and I make it my endeavor to follow such cases for a period of at least six months pretty closely, and I would pursue them even longer, but by the end of that time they are usually well enough to get tired of bothering with reports to the physician and disappear.

DISCUSSION.

Dr. William G. Spiller, Philadelphia—So many cases of hysteria are seen in Vienna and Paris that the danger of mistaking organic disease for hysteria is possibly greater there than in America. A most interesting case of hysteria, resembling ascending neuritis, was brought to me by Dr. Rugh a year or two ago. The patient was a young girl who had run a needle through the end of one finger. She was told by her friends of results known to follow such injuries, and her arm soon became purple and swollen. The case was treated at first as one of neuritis, and some improvement occurred under this treatment, but the symptoms returned. I then saw her in consultation with Dr. Rugh and found the arm very much swollen and painful, and placed on a splint, but motion of the fingers at this time was fairly good. During the night following my examination the pain suddenly ceased, and when I saw her the next day she had no movement and no sensation in the arm. I decided that the case was probably one of hysteria, and suggested to Dr. Rugh that he should remove the splint at once and give her the proper treatment based on suggestion. He did so, and after two or three days all the symptoms had disappeared. Dr. Rugh has told me that she has had one or two similar attacks since, but that they were always cured by suggestion.

It is sometimes very difficult to make a diagnosis between hysteria and other functional diseases. Krafft-Ebing recently reported a case in which the tremor was very much like that of paralysis agitans, but because it commenced simultaneously in both upper limbs and had existed for many years without rigidity, and because the knee-jerks were not exaggerated, he regarded it as probably a case of hysteria.

Dr. C. K. Mills and I have had under observation a patient who undoubtedly had hysteria and signs also of Parkinson's disease. The position of the body was very suggestive of paralysis agitans. We think it is impossible to say at present whether this case will prove to be one of paralysis agitans or not. If it should prove to be a case of this disease I think we should make a mistake in saying that it was one of hysteria that had passed into paralysis agitans. I have now under observation a case in which I find it impossible to make a diagnosis between hysteria and Huntington's chorea.

I have seen a young woman who had fallen from one of the galleries during the burning of the Ring Theater in Vienna, and for many years following this event the symptoms that developed made a diagnosis between hysteria and disseminated sclerosis very difficult.

Dr. Douglas Graham, Boston—I have been very much pleased in hearing such an interesting résumé of "Fat and Blood, and How to Make It." Many years ago I called attention to the fact that the indiscriminate use of oil in doing massage was an excuse for ignorance, and I am glad to find this statement confirmed by what Dr. Mitchell says.

Dr. Briggs—I would like to ask Dr. Mitchell as to the use of oil in massage, and on what he bases the conclusion that it lessens the value of the massage. I saw one case in consultation a few years ago where there were most undoubted hysterical symptoms at the beginning of true meningitis that destroyed life in three or four days after I saw the patient.

Dr. Cooper—While Dr. Mitchell's paper laid great stress on the technic of the treatment of hysteria, he did not lay as much as I would like to have heard on that particular phase of the technic which has to do with the moral treatment of the patients. There seems to be no definite way of getting hold of their moral life and placing it upon a purer and better plane.

Dr. D. J. McCarthy, Philadelphia—As to the differential diagnosis between organic disease and hysteria, while I would not go as far as Dr. Lloyd in saying that every case of hysteria has an organic basis, still I think you can find certain cases in which there is an organic basis for the disturbance. During the past year a case came to Dr. Burr, and later the specimens were sent to me—a case which had been diagnosed as hysteria. At the autopsy nothing gross was found, but while the cerebrum was as large as the average, the pons itself was distinctly smaller. The spinal cord had developed into two distinct spinal cords, and finally joined. Evidently there was a defective development of the central nervous system, with lessened resisting and recuperative powers.

Dr. A. E. Sterne, Indianapolis, Ind.—There are certain conditions of an organic character that offer a greater opportunity for confusion than do tumors of the brain. It seems to me that among these syphilis ought to take a more prominent rôle than has been given. The mutability of symptoms in hysteria is seconded very closely by the mutability of symptoms in syphilis. This is also true in regard to the change of the color fields. Another point that ought not to be lost sight of is that hysteria in males is a very different thing from hysteria in females, so far as its manifestations are concerned. The symptoms are very much more stable in males than in females, so far as my own experience goes.

In a case at the hospital, not long since, one which I was preserving for a specially good clinic, a large negro, six feet two or three inches tall, who had been a cement worker, carrying hods and barrels, had suddenly lost the use of the entire arm and leg on one side. We had the characteristic hypothenar symptom of syringomyelia, and he had some of the other characteristics, so that I left the diagnosis open. A few days later, in the clinic room, on examination I found that not a single symptom of that which had been present was there, and I was holding a clinic on a perfectly well man. I have since been in doubt whether I had a case of hematomyelia or hysteria. I believe it was a case of hemorrhage in the spinal cord and not hysteria. Most of these patients are constipated before they take the rest cure. A very large percentage of the hysteria is due to the long-standing constipation. It is not the diet particularly which causes the constipation. I never give milk with anything solid; I believe that milk is not to be digested, but simply to be absorbed.

Dr. G. W. Drake, Hollins, Va.—All hysteria has an organic basis. If people imagine they are sick, they are; there is an abnormal condition in some part of the nervous system. In listening carefully to the discussion of treatment it was evident to me that, while some of the gentlemen have tried very hard to make the differential diagnosis between organic diseases and hysteria, yet their treatment of hysteria is along the line of the treatment of organic disease. They are careful about the diet, and they give massage, and all their treatment is material. Because a lesion can not be seen with the microscope is no proof that it does not exist. Every ache or pain has a material pathology, and every abnormal action or disordered function is the consequence of a material disorder.

Dr. D. I. Wolfstein—I would be very much obliged if Dr. Mills or Dr. Mitchell, in closing, would try to draw the line a little more closely as to those cases which are not proper cases for the rest cure.

Dr. Charles H. Hughes, St. Louis, Mo.—I should couple with the rest the diversion cure and the change of environment cure. There are patients to whom in my experience the rest cure has proved the most restless kind of cure. So while I regard the rest cure for a certain class of overstrained society people, the class who largely came under the elder Mitchell's hands, and with whom he had the best results, as an excellent thing, there are patients to whom it is not applicable.

Dr. Charles K. Mills, Philadelphia—One matter to which attention was called is very important, viz., the diagnosis of hysteria from syphilis of the nervous system. Because the tracts of the nervous system are not found properly developed in a certain case, or a certain portion of the nervous system is relatively undeveloped in another case, apparently normal during life, except for the presence of hysterical symptoms, it is not just to argue that in such findings we have the anatomical basis of hysteria. The truth is that hysteria occurs in individuals of almost all types of organization, normal and aberrant. Every neurologist has seen hysteria in high-grade imbeciles, or has seen hysterical episodes in paranoiacs, and has seen the true hysterical stigmata in different varieties of insanity. On the other hand, he has seen under the influence of toxic causes, or mental strain, or profound physical exhaustion, or whatever cause, internal or external, a true hysteria develop in individuals not suffering from any form of insanity or arrested development.

Dr. **John K. Mitchell**, Philadelphia—Several questions have been asked about the uses of massage. As to why oil should not be used, any one who has practical experience in manipulations with or without oil, or has attempted at all to do them himself, knows that deep kneading, which is the most important procedure of massage, altogether the most important, can not be properly done with the skin oiled; further, that any diminution of the small amount of friction which takes place between the skin and the hands of the operator is undesirable, because that friction is part of the treatment and should not be lessened in that way. This is quite apart from the unpleasantness of being greased all over, and the encouragement of the growth of hair, which you will find in women, is a great objecton to the use of oil.

Dr. Cooper asks why I did not preach a sermon for which I have not had the text supplied. If he will supply the text in the person of a patient for whom he wishes to know the proper moral treatment, I shall be glad to try to answer him. The moral, unlike the general physical treatment, is different in each case, and must meet the exigencies of each particular problem.

Dr. Herman suggests that effleurage massage might be used. I distinctly said not effleurage. Deep kneading is the kind of massage we make most use of. Effleurage is extremely irritating to most nervous patients

As to contraindications, these are not very numerous. Certain forms of acute disease seem to me to stand in the way, and, of course, the dispositions of certain patients render them unsuitable subjects for this form of treatment. We began by excluding such cases; we began by saying in what way the cases suitable for the rest treatment should be selected.

Finally, Dr. Hughes, who had not heard what I said, criticized what he thought I had said and what he thought I had omitted. I am quite sure that no sane person has ever proposed the rest treatment as an exclusive system or a universal panacea, or said that it is desirable for all cases; and Dr. Weir Mitchell has repeatedly said that he never thinks of using it until every other possible means of treatment has been exhausted. As to its being a method suited only for women suffering from too much fashionable society, I think I treat almost as many washerwomen and quite as many school teachers as those from any other class of life. If these persons are overstrained from social diversions I am afraid the poor souls will not be allowed much amusement. I can only insist and repeat, finally, that it was not proposed as a universal panacea, but only as a last resort, because of the immense time which it takes, and the great expense which it entails.

HEREDITARY SUBNORMAL COLOR-PERCEPTION.*

F. SAVARY PEARCE, M.D.
Clinical Professor of Nervous Diseases in the Medico-Chirurgical College of Philadelphia, and Neurologist to the Philadelphia Hospital.
PHILADELPHIA.

Subnormal color-perception frequently presents a grotesqueness which always subtly attracts the attention of students of medicine and psychology. That there is a physical basis for this aberration of the sense of sight, is proved, although at times it seems necessary to search for the origin of the peculiar condition by assuming some metaphysical or vital perversion of energy of the human body causing an incoördination of neuronic action from the impinging light rays. Speculation, however, may be indulged in as to this type.

The more intimate we become with the knowledge of family histories found in such types of diseased functions, the more apt we shall be in determining the possible atavistic tendency to this state; and in knowing this possibility, we are as physicians made better able to cope with the broad subject of consanguinity of marriage or, indeed, of marital union of persons having any "weak points" in their moral, mental and physical composition. Then, too, the subject of education in this broad light is interesting food for thoughtful research. This optimistic side of evolution can be better balanced with degenerative tendencies in the race; and by detailed studies, therefore, of regeneration and tendencies to shoot into a higher life, we may hope to bring it about in some measure. The preceding thoughts emanate from the fact that lowered color-perception occurs much less frequently in women than in men. By some it is said that only one woman in 3000, or .03 per cent., is subject to perversion of the color sense; and that one in 25 men, or 4 per cent., is so affected. This difference must be largely due to cultivation. It is also patent to us that acuteness of color-perception varies in persons of the same sex. In a recent "Study of the Deaf and Dumb,"[1] the impression has come to the writer's mind that they have a peculiar nicety of perception of the sense of color. It is very likely a compensatory epiphenomenon, just as the blind are said to be more acute in acoustic and touch perceptions.

The rather rare condition of an instance of color-blindness in a woman, as recorded by Drs. Holmgren, Jeffries and others, bears also on the subject of the heredity of the disorder, inasmuch as the transmission of the color-defect frequently runs through several generations, much as do the organic pigmentary defects of the retina and optic nerve degeneration as shown by Leber, Habershorn, Norris, Oliver, and Gould.

In reference to relational ties in such cases, Wilson and Jeffries tersely say that few of the adult color-blind whom they have tested did not know of some blood relative similarly affected. Consanguinity in ancestral marriage has long been known as causative to a marked degree.

Horner's law as to the hereditariness of subnormal color-perception bears very notably on all such cases. Briefly, he says: "The general law is, therefore, that sons of daughters whose father was color-blind are most likely to be the same, although not without exception; or color-blindness is transmitted in the revertible type from grandfather to grandchild." In support of this, Magnus says: "The heretidariness of color-blindness has been known as long as the defect itself. All who have seen many color-blind will have noticed that it was in their mother's family that other cases were found. I have frequently been assured that this or that cousin on the *mother's* side was also color-blind; and, now and then, that a more distant relative of the mother had also color-blind sons. In view of Horner's law, this is readily explainable; and this peculiar law is all the more interesting since we find that it is the same in reference to the heredity of other physiological abnormities or defects."

As a more or less imperfect contribution to the subject, the record of the following case is herewith given. J. W. T. reported at my office on Feb. 15, 1898, suffering from hypochondriasis and recurrent melancholy. The man was very intelligent, and it was evident his social position, living among a set of uneducated relatives, "much annoyed" him. He had well-marked arteriosclerosis. The urine contained pus from the bladder cells and was alkaline in reaction—this the result of chronic cystitis following hypertrophy of the prostate gland. There was slight accentuation of the aortic second sound, but there were no evidences of other organic disease elsewhere in the body. There is no need of detailing mental phenomena other than stated.

This man could not distinguish red from green. The eyegrounds and the interior of the eye appeared normal.

---

* Presented to the Section on Nervous and Mental Diseases, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

[1] American Annals for the Deaf, January, 1901.

There were no reversals nor contractions of the visual fields nor optical defects. He had discovered the abnormal color-perception years ago while a seaman, when he frequently placed red and green lights in false positions, thus causing him to lose his situation.

Of his children, one had chorea; one daughter was very nervous; one suffered from lateral curvature, and a girl aged 15 years also, on repeated testings, had been proven to have a lowered degree of appreciation of red and green. She was well otherwise. There were no other discoverable cases of subnormal color-perception in the family.

The patient's mental fabric was always queer. A year after I saw him he became insane—delusional—and was committed to an asylum for the insane, in which he died some eight months later. Dr. D. D. Richardson, in the State Hospital for the Insane at Norristown, was kind enough to send me the notes of the autopsy, in which it is stated that there was an absence of organic disease of the brain.

This case is most interesting because, in the words of Oliver,[1] "this fault of optic-nerve structure, which does not show itself for several years after the birth of the individual, indicates to the writer's mind at least that there is an inheritance of a physical material which is not only shorter lived than that which is found in the same organ in other organisms, but that it has a briefer existence than the other organs in the same general organism, a fault which shows that an imperfect material has been born, and dies prematurely because it is subjected to an amount of wear and tear that would not seriously disturb or injure a properly formed substance. Further, it serves as a living evidence that a substance has been improperly made, most probably on account of physical imperfection and repetition of faulty cell combination of similar kind extending through several generations: an evidence, which in measure, says that primarily acquired pathological characteristics of structural form may be transmitted through forthcoming generations, as imperfect formation of similar structure in due proportion to both the want of hygiene and care given to the afflicted subjects, and the reassociation of similarly degraded developmental cells; an evidence which gives answer in part to the transmission of ordinary structural characteristics, which, if acted upon in the same way as those which are not made, as it were, in the same peculiar manner, will produce far different and even what may be determined idiocratic results."

Singular as it is, the idealistic genius may yet be subject to subnormal color-perception, as in the case of our poet Whittier. In these instances we are baffled by man's limitations of knowledge to an annoying degree.

1407 Locust St.

DISCUSSION.

Dr. G. W. Drake, Hollins, Va.—The paper is valuable to me in the fact of its arguing a physical material basis for the trouble. Heredity and environment make the man. Heredity has reference to the material constitution. We transmit to posterity our material peculiarities and so we transmit these mistakes or errors of function—abnormalities of form and structure. Color-blindness is the result of an abnormal condition of the color or visual center, which may be transmitted from father to son, and you will find it often traceable to heredity. The paper is valuable in that respect, and I note and call attention to the fact that there is a growing tendency—and you will *notice* it in every meeting of the Association—to materialize these troubles, and, as I remarked yesterday, some of our diseases that are misnamed will be corrected. I think the paper is a very valuable contribution to the Section.

Dr. Robert H. Porter, Chicago—In reading and discussing papers before this Section the word "abnormal" is often used when "morbid heredity or morbid nerve manifestations" would more accurately express the idea of the reader or speaker. When disease makes sufficient impression on the organism to be transmitted from one generation to another, to simply say that it is an abnormal manifestation, the term is hardly accurate enough to convey the proper idea or meaning. It requires a strong impression to make the individual deviate from the normal and in *medicine* at least the effects should be called morbid, instead of abnormal. The paper read was of great interest to me on account of showing the relation that color-blindness has to other tendencies to degeneration. Most morbid nerve manifestations are associated with deterioration in some part of the nervous system. And, in the study of these problems I think that as the pathologist increases his investigations and the powers of the microscope are extended, the tendency will be to find structural change in the nerve cells. Perverted nutrition and disordered circulation of the blood are associated with most chronic nerve maladies, and sooner or later these are likely to produce structural changes in the cells or fibers of the nervous system.

Dr. F. S. Pearce, Philadelphia—I wish to express my wonder that all this mysterious class of hereditary disorders being transmitted through the unaffected mother as a rule, and generally to a son, as for example, in hemophilia. Pathologists tell us that a pigmentary degenerative disease of the retina is transmitted in the same fashion, i. e., through the mother, and presenting signs only in the male sex. While the point mentioned in the paper—early youth being the time for the manifestation (not that I believe subnormal color perception exists in earliest childhood in the majority of instances and the patient simply did not know that he was color-blind)—is unexplained, it may be that after a beginning steady use of the eyes, the faulty structure existing, a chemical change in the cell takes place, which may not even be seen in our methods of careful microscopic examination. Then, when the sight is taxed, the cell-function is overwrought, and finally degeneration takes place, bringing about the abnormal or morbid function at this particular epoch of life.

THE SIMPLEST EXPLANATION OF THE FUNCTIONS OF THE NERVOUS SYSTEM.*

G. W. DRAKE, M.D.
Resident Physician and Professor of Physiology, Hollins Institute; Emeritus Professor of Physiology, Chattanooga Medical College; Ex-President, Tennessee State Medical Society, Etc.
HOLLINS, VA.

This paper is designed to be simply a suggestive presentation of the subject, not an exhaustive exposition. It is a brief rehearsal of the method employed by me in teaching physiology at the Chattanooga Medical College.

The key to the simplest explanation of the functions of the nervous system is, in my opinion, to base all nervous phenomena on the hypothesis of the existence of a specific energy peculiar to nervous tissue. It also very much simplifies the explanation to give to this energy a distinctive name and assign it a place with the natural energies. Conferring on it the dignity of a name will emphasize its importance, and it will be easier and more interesting to study its action and formulate its laws.

The rapid development of the laws of electricity, and its many practical uses are, doubtless in a great measure, due to the differentiation and naming of this energy so soon after its discovery. It was better that Röntgen's discovery was named X-rays than to have had no name.

It would not be inappropriate to call the specific energy, peculiar to the nervous system, "neuricity," from the Greek *neuron*, as electricity was named from *electron*, and for no better reason. The brain contains storage batteries of neuric energy for the supply of motive power to all the muscles and other organs and tissues of the body. Every voluntary muscle has its little storage battery in the motor area of he brain, from which energy is discharged by the action of the will. When it is desired to move the arm, the will discharges the storage batteries for the muscles needed, and neuric energy flashes along certain fibers of the corona radiata, the posterior limb of the internal capsule, the crusta of the crus, the pyramids of the bulb, the anterolateral columns of the cord, out of the cord by the anterior root of a spinal nerve, and along that nerve and its branches into the muscles, causing them to contract. In an analogous way may be explained the motion of other parts of the body controlled by the action of voluntary muscles. By this method the anatomy of the brain, cord and spinal nerves is made a more interesting study, and the practical necessity of a knowledge of it is demonstrated.

---

[1] Proceedings, American Philosophical Society, vol. xxxii.

* Presented to the Section on Nervous and Mental Diseases, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

In the medulla oblongata are located the little storage batteries for the supply of neuric energy to the involuntary muscles and to the glandular organs of secretion and excretion—to the liver, the lungs, the kidneys, the heart and blood-vessels, the salivary and peptic glands, etc. The spinal and ganglionic nerve-centers are subordinate storage batteries dependent on the dominating batteries in the brain, from which they are constantly re-energized. Sever their connection with the brain and the action of the organs which they supply soon ceases. The heart will beat when removed from the body, but only for a short time, on account of the impossibility of re-energizing its ganglia.

SENSATIONS.

Passing hastily over this part of the subject, we come next to the sensations. The simplest and most satisfactory explanation of the special senses is as follows: The brain, in the dark camera of the cranium, contains sensitive protoplasmic plates adapted to the formation of images by the action of neuric energy, and the pictures thus formed should be called neurographs. Sensations are the perceptions of neurographs by consciousness. The sensation depends on the neurograph, and the latter on the character of the cerebral plate on which it is formed and that of the peripheral endings of the nerves with which it is connected.

The Sense of Hearing.—Sound waves striking on the membrana tympani communicate vibrations to the internal ear, causing the liberation of neuric energy at the peripheral endings of the auditory nerve, and this is conducted to the auditory center of the brain, and there makes a neurograph of sound.

The Sense of Seeing.—Light from an object, falling on the retina, liberates neuric energy, which is conducted by the optic nerve and other fibers to the visual center of the brain, and there makes a neurograph of light. The beholder can not see an external object, nor its image on the retina, but a neurograph on the brain corresponding to the retinal image.

The Sense of Touch.—Mechanical touch communicating pressure to the peripheral endings of sensory nerves liberates neuric energy, which is conducted by afferent nerve-fibers to the sensory center of the brain, and there makes a neurograph of touch, corresponding to the character of the impression made on the peripheral nerve endings.

The Sense of Smell.—Odoriferous particles coming in contact with the membrane in the nose liberate neuric energy at the peripheral endings of certain nerves, and this is conducted to the olfactory center of the brain, and there makes a neurograph of smell.

The Sense of Taste.—Sapid substances in the mouth liberate neuric energy at the peripheral endings of gustatory nerves, and it is conducted to the gustatory center of the brain, and there makes a neurograph of taste.

The Sense of Pain.—Lacerations, lesions, and hurts of any kind liberate neuric energy at the peripheral endings of certain sensory nerve fibers, it being conducted to the pain centers of the brain, and there making a neurograph of pain corresponding to the impression on the part affected. The sensation of pain is the perception of a disordered or abnormal neurograph, and has a material pathologic basis, either in the cerebral plate or some part of a sensory nerve with which the latter is connected. Every ache and pain has a material pathologic basis—a molecular disarrangement or displacement of matter.

The Sensation of Heat.—Sensations of heat are the perceptions of neurographs of heat formed on the brain by neuric energy conducted from the peripheral endings of sensory nerve-fibers, and liberated by the application of heat.

I do not believe that the heat and pain centers of the brain are the same, and I do not believe that either is identical with the centers of touch and general sensibility. These centers are as different as the sensations of which they form the material basis. Form determines function. Internal molecular changes are not necessarily manifest in a change of the superficial form, but they are, nevertheless, the basis of altered function. There is a distinction between internal and external form. The latter is visible, the former invisible. After the departure from a mass of matter of vital energy the internal form is changed by the action of chemical energy, and so the physiologist is prevented from determining the character of the living form, the microscope revealing only the superficies of the dead bodies, and chemistry analyzing the constituent elements.

The relative positions of molecules in cells and atoms in molecules are changed after death, and they doubtless undergo many changes in life, in response to the action of the various natural energies, but all modified and dominated by the presence of vital energy. It is interesting to study the neurons in the brain, and to imagine the great diversity of molecular movement produced by the action of neuric energy. The brain is a living kodak, constantly at work taking sight, sound, smell, taste, touch, and also mind pictures. It is covered over with neurographs resulting from "impacts" and "impulses" on peripheral nerve-endings in the various sense organs, and also from impulses of the mind. These neurographs are discernible to the consciousness of the individual in whose brain they are formed, but can not be demonstrated by scalpel or microscope. They are the product of the changed relations of molecules in neurons or atoms in the molecules or changes in both.

Consciousness learns the significance of these changes by experience, and transmits its knowledge to the mind.

It is important to make a sharp differentiation between brain and mind, and to avoid the use of the terms cerebral and mental as interchangeable synonyms. The brain is the mind's organ and medium of manifestation. It is the head of the nervous system, and contains different centers for the different faculties of the mind, and separate centers for the various sense organs, muscles, and glands of the body, together with pathways for neuric energy between the central and peripheral nerve-endings.

The study of the cerebral centers, their intercommunications and their nervous connections with the peripheral organs and tissues, is essential to a knowledge of the causes of the various insanities and monomanias, the defects of the special senses, and the disorders of muscles and glands.

Not alone because the brain contains the intellectual and other psychic centers is it the most important organ in the human economy, but also because it contains the dominating storage batteries of neuric energy essential to the normal condition and functional activity of every tissue and organ. Centripetal and centrifugal energies control the movements of the planets, gravitation pulls the apple from the tree and hurls it to the ground, electricity runs the telegraph and telephone, and neuricity governs the man machine.

The energies are only known through their action on matter, and their names are arbitrary and conventional, but none the less essential and convenient than those of matter. Much would have been gained by assuming, long ago, the cause of nervous phenomena to be one of the natural energies, and giving it a specific and permanent name. While I do not insist on giving the agent of nervous action the name "neuricity," I do protest in favor of some name, any name, even if it be Y or Z, X having been already appropriated. Dispensing with such ill-defined and obscure terms as "nerve force," "nerve impulse," etc., which tend to confuse, and fail to satisfy the student of physiology, will remove much vagueness and greatly facilitate the study of neurology. I would be glad to see a uniform and systematic study of neuricity inaugurated, with the view of unfolding its laws, and demonstrating its correlation to the other natural energies. By this line of research will be developed the simplest explanation of the functions of the nervous system.

The failure to properly differentiate brain and mind has assigned to the domain of metaphysics and psychology work which belonged to the departments of physics and physiology. The functions of the brain are often confounded with the faculties of the mind, and, as a consequence, cerebral are misnamed mental diseases.

DISCUSSION.

Dr. D. I. Wolfstein, Cincinnati—I think that the reader of the paper is to be congratulated for having evolved for himself and the students a rather simple set of similes which are to make nervous force seem plain to them, but I do not think that anything could be done to the science by denominating the nervous force as neuricity. It is only a multiplicaton of terms to say neuricity. It reminds me of the saying of Goethe, that when our proper ideas are completely wanting the proper word usually occurs to us. I think this is the case here. The gentleman is naturally attempting to bring back to a material basis a great many things that probably never will be explained on such a basis, although that is the hope. As I said, I simply wish to emphasize the fact that it would be rather undesirable if we would want to introduce into the already overburdened nomenclature a class of names that would not simplify the subject.

Dr. G. W. Drake, Hollins, Va.—It is very evident that my friend and critic did not comprehend my paper. I have had this theory, as you might call it, in my mind for years and years, and this is the first opportunity I have had of putting it on record, and I want it on record, because I believe the future will show the justice of the claim I make. Scientific investigation is coming around every session toward the views advocated in my paper. Note the session at St. Paul and every one we have had for several years—they all made the material basis of nervous phenomena paramount. But I have reference to his mistaking my meaning. I said I did not care anything about the name; just let us determine on some specific name, so that it could be studied as an entity and not a vague and obscure thing. The force or energy I am describing, I will take his name for it, if he will take my theory. The mistake he made was in believing that I confound neuric energy, as he said I changed the names several times; I did not. He may say I change the name electricity when I say electric energy. I spoke several times of neuric energy instead of saying neuricity.

Just give that peculiar energy which belongs to the nervous system a name, or give it no name, but study it as an entity and as one of the natural energies, but I do insist on a name of some kind. But it is not vital energy; that is the point, showing that he did not comprehend my paper at all. Vital energy is in every cell of not only the human being, but in every cell of every vegetable in the universe. Every cell has vital energy, but nerve-cells alone neuricity, a peculiar energy associated with the nervous system. Force and impulse and all such terms are confusing. A peculiar energy belongs to the nervous tissue. Whether it is confined to it I can not say. If you will give that a name and study it, it will greatly facilitate the explanation of nervous phenomena.

PSYCHIC THERAPEUTICS.*

J. C. CULBERTSON. M.D.

CINCINNATI, OHIO.

A dictionary definition of this term says, it is "a systematic use of personal influence, especially that of the physician, in treatment of nervous diseases." In this definition may be found a good and sufficient reason for the success of some practitioners of medicine and apparently unaccountable failure of others. Nor is failure or success attributable to the specific materia medica remedies made use of by the physician in attendance upon the sick.

The influence of the mind over the body in conditions of health as well as of disease is always paramount. In a consideration of this influence, it is desirable that we remember the prime subdivisions indicated by the will, intellect and emotions. Together, these constitute and are the faculties of the mind. In health they are in a state of equilibrium. In sickness the balance is disturbed. The will becomes weakened, as shown by an increased pliability [illegible] The intellect is disturbed, which is [illegible] impairment of judgment and ability to reason, while the emotions through weakness itself become exaggerated.

These are the general physical and mental conditions which confront the physician in his daily work, and the way in which he meets them is of equal significance with his prescription. If he inspires confidence by his presence, a material factor has entered the lists as a remedial agent, but skepticism or doubt of professional ability will act as a disadvantageous element in its psychic influence upon any patient. Hence, the doctor himself becomes a powerful therapeutic agent. When strong in his perceptions, firm and positive in opinion, confidence is engendered. His will and judgment are made to dominate that of the patient and patient's family.

On the other hand indecision, wavering and apparent uncertainty militate against both physician and patient to the degree in which it is apparent. There is a psychic element present in all conditions of disease; and in some maladies may be said to hold the fort. So dominating are they in character that they sometimes completely overshadow actual pathologic states. This is particularly the case among many who are highly educated, refined and cultured. Their education, culture and environments develop a supersensitive organism of the mental and nervous system that is productive of symptoms of hysteria with its long train of sympathetic troubles ascribed to so-called functional derangements. So strong are these influences, that they not infrequently dominate and mask everything else that is manifestly present in a given case.

---

* Presented to the Section on Materia Medica, Pharmacy and Therapeutics, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

The first and most important factor in a treatment of all such cases is to be found in a systematic use of the personal influence of the physician over his patient. This will take character and manifest itself in accordance with the dictates of his own judgment, and his plan of treatment will be as variable as the number of patients recorded on his visiting list. A discriminating use of positive instructions with placebo adjuncts is often as imperatively required as a so-called heroic treatment with drugs. Because of a recognition of this potent element in a treatment of diseased conditions, many, not a few, but many old practitioners become more or less skeptical in their appreciation of the value of drugs as curative factors, and their public expressions along these lines give a strong support to so-called hypnotists, "christian scientists" and faith-cure believers.

"A legitimate practice of medicine takes cognizance of all psychic influences and turns them to account in a treatment of disease. The personal influence of a physician should always be firm, not vacillating, positive and never negative. These attributes tactfully administered are sedative and may be anesthetic and narcotic. They possess the therapeutic property of being able to allay irritability and excitement. To illustrate: a visit to a dentist will usually allay the torment of a toothache, while the entrance of a physician within the lying-in chamber ameliorates if it does not completely arrest the throes of labor pains in a parturient woman. The personal influence of the physician in these and a whole host of actual pathologic as well as functional disturbances may become a most potent factor in this treatment.

Phobia or fear and joy are powerful psychic factors in both cure and causation of disease. Either will in a supersensitive individual produce pain or fatigue, exaltation or depression, thereby exciting the entire sympathetic nervous, muscular and glandular functions of the body. Under their influence the sphincters relax, a large amount of light limpid urine is voided, the functions of the liver and alimentary canal are disturbed, being either suppressed or exaggerated. For a control of these abnormal states or conditions the personal influence and suggestions of the physician are singularly powerful and effective.

This same personal influence of the physician is often most potent as a therapeutic agent when agreeing with the expressed or unexpressed wishes and desires of the patient.

Hope, the very anchor of the soul, prolongs life and sometimes saves it through the cheerful and positive assurance of the attending physician. The wise man who is a successful practitioner, uses his personal influence as a stimulant, sedative, anodyne, narcotic, anesthetic and nervine; and does it systematically, as though it were as important a therapeutic measure as the giving of a tonic, purgative or opiate. It is this personal influence that makes some men great and others small.

All that is known of the entire materia medica, as well as other resources in the art and science of medicine, are as wide open to the command of one physician as of another, and the differentiation between them is founded upon but two accomplishments: ability to diagnose pathological conditions and a systematic use of personal influence in the treatment of disease. All other therapeutic aids are but valuable adjuncts, not one of which is to be for one moment in the slightest degree deprecated, for they are cofactors of the greatest importance. It is this systematic use of the personal influence of the physician that gives any foundation to christian science or faith curists. Eliminate this one powerful agent and there is nothing left of a visionary vagary.

The influence of environment and suggestion is as much a legitimate part of the reputable physician's armamentarium as a medicine chest or an instrument case; and no part of their value as therapeutic agents is conceded as belonging to quacks and charlatans. The whole domain of life, with all that is collateral to it from horizon to horizon, is in the broad and unlimited field of legitimate medicine. The personal influence and its systematic use is but a single therapeutic agent, and it is so potent and so powerful that its importance can not go unrecognized in a successful practice of the healing art.

DISCUSSION.

DR. T. B. GREENLEY, Meadow Lawn, Ky., said that he had seen a number of hysterical cases in which the symptoms were due directly to suggestions by the patient's friends. He referred to one case, that of a young woman who lost her voice. He decided that it was all imagination and gave her a placebo, but gave her very specific directions as to its use, and found her all right at the next visit. Another thought she was paralyzed and had spells like convulsions, which were clearly excited by the suggestion of her mother. He left a liniment with very particular directions about its use, and the next morning she was all right.

DR. A. BERNHEIM, Philadelphia, said that suggestion treatment loses some of its value by show performances. He thinks that doctors can do a great deal of good by psychotherapeutics. He has seen several cases treated and cured by psychotherapeutics. Hypnotic exhibitions are prohibited by law in Germany, as they may do much harm when in the hands of charlatans, and particularly because many patients may resent any treatment that has been exhibited on the stage. Psychotherapeutics can be utilized in practice. He cited the case of a young man who had to rise ten or twelve times a night to urinate. No cause for this could be found. He told him firmly that he must not get up, and the patient informed him later that he has since only had to get up once at night. He tested him by asking him if he ever had earache, and the next time he came, he said that he had earache.

DR. F. G. WHEATLEY, North Abington, Mass., said that the paper opens an exceedingly important field of therapeutics and one which teachers of therapeutics do not sufficiently recognize in the regular course of instruction given in the colleges. The tests of the ordinary medical examining board do not take into account the personality of the individual at all, and yet this personality is such an important element in the success or want of success in life that it seems as if it should be taken into consideration in granting licenses to practice medicine. The power of some physicians to influence patients has more to do with their success than their scientific attainments. A man may learn all that can be learned and pass his examination with great credit and go into practice and be a failure because he can not impress his clients with the idea that he can do them good. This power is not only of value in hysterical cases, but in others as well. If we can make our patients believe that we know what we are about and can do them good, the results will be satisfactory, but if we simply give them advice, without impressing on them our personality, we lose a great element of success. As the speaker said, there is an imaginary element in therapeutics and the use of this is one element of success. This is now principally in the hands of "Christian scientists" and the like. Until the medical profession meets this in a proper way we shall meet with persons who believe that faith and Mrs. Eddy can cure them when the best doctors fail to do so.

DR. J. N. UPSHUR, Richmond, Va., cited the case of a woman who had been sick for three weeks with gastric catarrh, but not of much moment. She had been in the hands of a young physician, who had certainly failed to impress her with his personality. At the time the speaker saw her she was not only convinced that she was very ill, but she was certain that she would die very soon. He made some recommendations which the doctor failed to carry out. Ten days afterward she was thoroughly disgusted with the treatment and, getting no better, the speaker was sent for and the other physician dismissed. It was learned that she had been in such great pain that the doctor had been giving her large amounts of morphin hypodermically daily. These were promptly stopped and she was told she would have to get along without them. She thought that she had a tumor in the neighborhood of the right ilium, and complained of persistent pain on that side. The speaker took a tape line out of his pocket and proved to her that both sides measured exactly alike and that there was no tumor. He never heard a word afterward of this tumor, and she got well very soon.

TREATMENT OF DEFLECTION OF THE NASAL SEPTUM

COMPLICATED BY TRAUMATIC DEFORMITY OF THE EXTERNAL NOSE.*

E. B. GLEASON, M.D.

Clinical Professor of Otology in the Medico-Chirurgical College; Physician in Charge of the Nose, Throat and Ear Department of the Northern Dispensary.

PHILADELPHIA.

For the purposes of this paper, deformities of the external framework of the nose are divided into two classes: flattening of the bridge of the nose, producing the deformity commonly called "saddle-back nose," and deflection of the end of the nose. A third class might be made of a combination of these two conditions, but would be without significance as far as concerns operations on the septum to secure increased breathing space. It should be borne in mind that operations upon the septum produce little effect upon the shape of the external nose, and are undertaken for the sole object of improving the breathing space.

Traumatic flattening of the bridge of the nose is generally due to the fracture of the base of the nasal bones, with dislocation from the nasal processes and depression of the nasal bones, with rotation outward on their long axes. The upper shield cartilages and sometimes the septum are involved. The most common lesion of the septum is a dislocation of the triangular cartilage and anterior portion of the vomer from their bony attachments. Both below and behind there is a deposition of new material, and usually a thickening, both of bone and cartilage. The result is the so-called septal redundancy. The septum has become too large to be crowded into the median line. The cartilaginous plates of the septum are also sometimes separated. Saddle-back nose does not interfere in the least with the success of an operation for deflection of the nasal septum, but lateral deflections of the external nose decidedly complicate matters.

Lateral deflection of the end of the nose is usually the result of fractures of both nasal processes, the nasal bones and displacement of the upper shield cartilages. The septum may or may not partake of the deformity. If it remains straight, it will no longer be parallel to the curved lateral nasal walls.

If deflected to a greater degree than the lateral walls, it will produce stenosis by encroaching upon the lumen of the naris of the concave lateral nasal wall. Therefore, the problem, in cases of stenosis in noses deflected to one side, is not to make the septum straight, but to render it as nearly as possible parallel to both lateral nasal walls. This is sometimes not easy to accomplish.

The methods that may be used to bring the septum into the median line will be considered with reference to septal redundancy, with reference to resiliency, and also with reference to the method of supporting the deviated area in its new position.

The simplest operation for the correction of septal deflection is expanding the strictured side of the nose with the index finger, which, with a slight boring motion, and with its palmar surface pressing upon the septum, is thrust through the anterior naris to a position beyond the deflected area. When carefully done the triangular cartilage thus can be dislocated from its attachments below and behind. The fragments overlap each other, thus providing for redundancy in both the vertical and horizontal diameters. The dislocated cartilage may be supported in a vertical position by a pin or tube. The operation has the advantage of being submucous. If septal redundancy was the main cause of failure in operations for the correction of septal deflections, nothing could be more simple or better than this operation.

It is not septal redundancy, but septal resiliency that is the main cause of failure in operations for deviated septa, and, because in operations where the mucous membrane of the septum is uncut, it is impossible to thoroughly bend the triangular cartilage; this operation commonly results in failure more or less complete; the septum sometimes remaining for several months in a vertical position and then gradually springing back into its former abnormal position.

The objections to simply removing the thickened angle of a deviated septum is that while it increases the breathing space in the narrow naris, it leaves the unobstructed naris in the same condition as before the operation. Often it is of the unobstructed naris that the patient complains and frequently when the ears become diseased, as a result of a septal deviation, it is that upon the same side as the unobstructed naris which becomes affected first.

Sajous describes in his book, published in 1885, what, he states, is the simplest operation for the correction of septal deviations. An incision is made along the crest of the deviation. The upper or movable flap of the septum is then pushed over and beyond the lower into the median line. It seems unnecessary to state that in Sajous' operation, when the upper portion of the septum is pushed over and beyond the lower, because of the septal redundancy, the parts overlap and the resistance of the lower flap tends to prevent the return of the upper into its former deflected position; but because a straight incision does not enable the flaps to overlap except in one diameter, either the horizontal or vertical redundancy is not provided for, and hence the resiliency of the septum is increased by the bending of the upper flap; because in either the vertical or horizontal diameter, the septum is crowded into a space too small for it.

In 1895, Watson described an operation, which he stated, was a modification of the well-known procedure of Ingals, but which was really a combination of the operations of Ingals and Sajous. A beveled incision was made through the crest of a horizontal deviation, and the vertical redundancy cut out with a knife, care being exercised in making both incisions that the mucous membrane on the concave side of the septum remained intact. In a paper published in May, 1899, he described his incision as along the crest of a horizontal deviation with a vertical cut from the anterior point of the first incision. The mucous membrane of the concavity of the deflection not being included in either incision, the first of these operations would seem to yield two triangular flaps; the second, one large triangular flap. Because the mucous membrane of the concave side of the septum is not cut through, and hence would prevent thorough bending of the flaps, it would seem that the operator's main object was to provide for redundancy, which is accomplished to the same degree as in the operations of Roberts and Asch, who also employ triangular flaps. Redundancy of a septal deviation, both in the vertical and horizontal diameters is provided for equally well by a stellate (*), a cross-shaped (+), an L-shaped, an inverted T-shaped, a horizontal H-shaped (⌶) or a U-shaped incision. This is not the case as regards resiliency.

---

* Presented to the Section on Laryngology and Otology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900.

Roberts stated that unless the resiliency of the flaps is thoroughly destroyed his operation will be a failure. Asch is almost equally emphatic as regards the necessity of thoroughly bending each flap in order to diminish, as far as possible, the resiliency of the septum. Doubtless the success of any operation for the correction of a septal deviation depends more upon the thoroughness with which the flaps are bent than upon any other detail of the technique.

It is the india-rubber-like resiliency of the septal cartilage, rather than the redundancy of a septal deviation, that interferes most with the success of operations for the correction of deviations.

Is there any method of overcoming this resiliency besides thorough bending of the flaps, which in the case of cartilage is never entirely destroyed by the most thorough bending? Leverage may be utilized by employing a quadrilateral flap. If its base be bent, the longer such a flap the more leverage has to be overcome to bring the edge of the flap into its former position. This is not true of triangular flaps, because the larger the flap the larger its base and consequently the greater its resiliency. The principle may be demonstrated by cutting flaps of various shapes in india-rubber balls. A narrow quadrilateral flap remains almost without support in the position in which it is bent. A triangular flap of the same size does not.

In lateral deflections of the whole tip of the nose, the part of the septum involved usually is not great and the deflection is of the so-called vertical variety. In some cases the area involved is not wider than the thickness of a lead pencil. It is difficult to understand how any operation by means of one or more V-shaped flaps could be done in a case of this kind. A U-shaped incision around the deflection, however, is readily made and yields a narrow quadrilateral flap consisting of the entire deflected area, and when the base of such a flap is thoroughly bent, it will sometimes hang in the position in which it is placed without any support whatsoever. If allowed to remain unsupported in the previously unobstructed naris the gradually returning resiliency of the base of the flap and the traction of granulations adhering from the upper ends of the U-shaped incision will gradually draw such a flap into the vertical line in the majority of instances; but there is always some danger of overcorrecting the deflection. It is, therefore, best to see that the flap is in the position desired one week after the operation. This was the method pursued in six cases of lateral deflection of the whole tip of the nose, four of which were exhibited at the Philadelphia College of Physicians.

The technique of the operation is as follows: The field of operation is cocainized and then exposed by means of a self-retaining speculum. A thin saw is introduced along the floor of the nose beneath the deviation. The sawing is continued in a horizontal direction until the saw has penetrated somewhat deeply into the tissues. The direction of the sawing is then rapidly changed to a nearly vertical direction. During the sawing it is of the utmost importance that the saw should be held exactly parallel to the septum; in order that the cut shall be around and not through any part of the deviation. The length of the vertical crura of the U incision is then quickly lengthened by means of a small bistoury curved on its flat, and the flap is thrust through the hole in the septum with the tip of the forefinger.

While the finger is still in the naris, it is carried up along the anterior and posterior crura in order to be certain that the edge of the flap has completely cleared them and the neck of the flap is then sharply bent. The whole operation can be done with considerable deliberation in two minutes. It is not necessary to denude the edges that are in contact, as the pressure results in necrosis at least of the superficial layer of the mucous membrane, after which the parts unite. Should nonunion result, the edges may at any time be freshened with a ring-curette, a simple and painless procedure.

It is well to slip in a tube immediately after the operation and decide twenty-four hours afterward as to the necessity of wearing it. The tube serves to control the usually trifling hemorrhage which, however, may be so excessive as to require the insertion of a large plug of absorbent cotton saturated with peroxid of hydrogen into one or both nostrils.

In my earlier operations for correction of septal deflections, I invariably used an Allen tube when support was required; later, a tube devised by Dr. D. Braden Kyle. This tube is somewhat similar in shape to those of Asch and Meyer, but is made of pewter and so thin that its shape can be modified by pressure of the fingers, or quickly pared to any desired shape with a penknife. Most recently I have had the Allen tube slightly altered in shape and made of this same material, and I find the readiness with which its length and shape can be altered to be a great convenience.

However, the question of support is of little consequence in comparison with that of counteracting the resiliency of the septum. The writer claims for his method of operating that the shape and position of his septal flap enables an operator to overcome resiliency more certainly than by any method previously described. When the resiliency of a quadrilateral flap has been destroyed, at least for the time being, by bending the neck of the flap at a right angle, the overlapping of the edges of the flap upon the septum as occurs in the operations of Sajous, Seiler, Watson, etc., affords sufficient support in more than 80 per cent. of the cases, and no tube is required. Beveling the edges of the flap is of no consequence, because it does not increase the resistance tending to prevent the return of the flap to its former deviated position.

DISCUSSION.

Dr. J. O. Roe, Rochester, N. Y.—I have been very much interested in Dr. Gleason's paper. His operation, as he has described it, is, however, like the Asch operation, adapted for the correction of deviations of the cartilaginous septum, and therefore adapted only to about one-third of the cases of deviation of the septum. The deviations of the septum may be divided into deviations of the bony portion, which comprise not more than 10 per cent. of the cases, deviations of the osseocartilaginous portion, which comprise fully 60 to 65 per cent., and deviations of the cartilaginous portion alone, which comprise about 25 or 30 per cent. of the cases. Therefore, in considering the correction of deviation of the septum we should take into consideration the correction of deviation of every portion of the septum and not the correction of the cartilaginous portion alone. In correcting lateral deformities of the nose, the lateral displacements which so often result from injuries, we have to take into consideration two conditions: 1, the cosmetic effect, and 2, the establishment of a normal condition of the nose for respiration. In operating for a cosmetic effect it is important that we should not lose sight of the respiratory function. Many patients apply to us for the correction of a deformity of the nose, rather than for the relief of insufficiency of respiration caused by the associated deviation of the septum. In correcting the deviation of the septum, therefore, we should take into consideration the correction of the osseous portion as well as the cartilaginous portion of the septum. For the purpose of correcting deformities of this portion of the septum as you may know, I devised a method of correcting it by means of fenestrated forceps.

One of the difficulties, as the Doctor has stated, is in overcoming the resiliency of the cartilage. In my experience this can not readily be overcome unless we correct the deformity at the osseocartilage junction. This is most easily *done by* means of the fenestrated forceps. If we attempt to force the deflection of the septum up to the median line with a flat bladed forceps we find it well nigh impossible to overcome the resistance, or re-fracture it at all, but by means of the fenestrated forceps, as I have indicated, you can force the deflection beyond the straight line as far as you choose. Thus you can refracture it without rotating the forceps and lacerating the septum. Some cases of brain abscess have been reported attributed to the laceration of the septum from the use of the flat forceps. With the fenestrated forceps this is entirely avoided. Dr. Gleason's ingenious method avoids this danger, but is especially adapted only to special cases where the deflection is confined to the cartilaginous portion of the septum.

Dr. F. J. Quinlan, New York City—We have been following an operation in the Polyclinic which saves much of the slough we have heretofore had in these cases. I will illustrate this. When we find, on one side, the angular deflection of bone, we introduce on the other side a solution of boric acid, as much as the tissues will hold, which causes a great sagging. We then push the deflection into the sagging and let it be. The injection is made between the folds of the mucous membrane, a saturated solution of boric acid being used, and then we produce a convexity on the side of the deformity that we wish to overcome, and thus we are able to retain the integrity of the mucous membrane. I have done this operation several times. By the method I have described we cause mutilation of the tissues on only one side. The mucous membrane is intact, which gives it an additional splint-like structure and holds the septum so as to prevent it swaying to the other side. I have had two or three sloughs following the method described by the Doctor.

Dr. Donne, Philadelphia—I would like to add my experience to the excellent results the Doctor has obtained. I have made the U-shaped flap he describes, and the operation is of value in those cases in which the cartilaginous septum alone is deflected. I wish Dr. Gleason would give us the benefit of his experience in septal deformity complicated by traumatic deformity of the external nose. But taking the main subject of his paper, namely, the description of his U-shaped incision, I am thoroughly in accord with what he says. In some cases I have found the operation of Asch or that of Adams or Roberts of more value, but in the cases with a broad base, where the U-shaped flap can be well made, the operation described by Dr. Gleason has been particularly successful. In these cases it is our duty to operate wherever we can induce the patient and the friends of the patient to consent, because many of the cases of middle ear disease are due to deflections of the septum, and we can often relieve headache and chorea and some cases of asthma by these operations. I am in favor of using general anesthesia in these cases. I use, locally, the extract of the suprarenal capsule to prevent excessive hemorrhage and give a better opportunity to see the progress of the operation. The use of general anesthesia is of value because it gives better control of the case, especially in children, who are easily frightened by the appearance of blood and instruments. I have had a number of those cases and no untoward results have taken place. Very frequently the use of the splint for twenty-four hours has obviated any hemorrhage either during the operation or subsequently. One of the particular advantages of the operation described by Dr. Gleason is the fact that the septum is then held in position by the other portions of the septum, and the tube does not need to be used over twenty-four hours, which is an advantage over the operations in which the tube must be used for a long time. The operation overcomes resiliency better than any other operation I have done.

Dr. E. B. Gleason, Philadelphia—I will say in reply to Dr. Roe that when a man or woman comes to me with a deviated septum I straighten it by my method whether the cartilaginous portion alone or both the cartilaginous and bony portions are involved. In the case I have presented quite a large portion of the bony part of the septum was involved. When the bone is involved far back it is sometimes much harder to make a long posterior crux with the knife. I generally use a double-edged knife, curved on the flat, for the purpose. In regard to the operation referred to by Dr. Quinlan as being done at the New York Polyclinic, it is an excellent one in those cases where only a very small portion of the septum is involved and where the length of the flap would entirely counteract the septal resiliency. In those cases where a large portion of the septum is involved the preservation of the mucous membrane interferes with the thorough bending of the flap and would be disastrous. I do not see any great advantage under any circumstances in saving the mucous membrane as has been described; and as one of the chief advantages of my operation over those employing triangular flaps is that it better counteracts the resiliency of the septum, the main cause of failure in septal operations; the mucous membrane of the concave septal surface is invariably incised in order to permit bending the flap as nearly at a right angle as possible. If the neck of the flap contains bone it breaks with an audible snap and the resiliency of that portion of the flap at least is entirely destroyed and gives no further trouble. Where the case is complicated by some deformity of the external bony framework it is a question for the patient to decide whether or not he wants an external operation done. You can secure good breathing space without an external operation.

Dr. Roe—In those cases in which you have a long bending of the septum extending from far back, if you were to cut a little segment in the middle and shove it through, the deformity would still exist. How do you do in those cases?

Dr. Gleason—I do not saw a little part out of the center, but I go entirely around the deflection. It makes no difference how large the deflection is. I have never seen a case where the pharyngeal edge of the septum was involved. I have never seen a case of deflection of the septum where, if I held the saw parallel with the septum, I would not saw around the deflection.

Dr. Roe—When there is a large deflection you would practically have to saw the entire septum.

Dr. Gleason—I have sawed two-thirds of the septum, and few cases will be found more extensive. But I would go further if I found it necessary. This case shows involvement of a large portion of the bony septum.

Dr. Quinlan—Do you put one or two tubes in?

Dr. Gleason—I use a large tube, which should drop in easily, and not be thrust in. If the slightest pressure is necessary to insert the tube the operation has been improperly done. The morning after the operation the tube is removed, and in rather more than 80 per cent. of my cases not again inserted. This was the history in the case brought before you. He visited my office every day for a week or so that I might inspect his septum, and in the meantime attended to his usual duties.

EXTENSIVE LACERATION OF THE EXTERNAL OCULAR MUSCLES; DIPLOPIA; SPONTANEOUS RECOVERY.*

WALTER L. PYLE, M.D.
ASSISTANT SURGEON TO WILLS EYE HOSPITAL.
PHILADELPHIA.

History of the Injury.—The patient was a practicing physician, aged 44 years, in good general health, and had never worn glasses. While riding a bicycle across his lawn at night, he ran into a blunt splicing hook of a clothes-line made of No. 10 telephone wire. The end of the hook entered the conjunctiva of the right eye, near the inner canthus, and tore its way out toward the external canthus, keeping below the cornea. The conjunctiva, subconjunctival tissue, and ocular muscle-tissue were extensively lacerated, and the end of the hook was found to be covered with blood, shreds of conjunctiva, subconjunctival tissue and fibers of muscle substance. The sclera was not perforated. The eye was dressed antiseptically and free boric acid irrigations were employed. Bleeding was quickly checked, and the wound healed kindly. However, there was immediate diplopia, which no prismatic combination tried by a local optician could relieve.

---

* Presented to the Section on Ophthalmology, at the Fifty-first Annual Meeting of the American Medical Association, held at Atlantic City, N. J., June 5-8, 1900

Subsequent Diplopia.—I first saw the patient about four weeks after the injury. He came into my office wearing a black patch over the injured eye to prevent the diplopia, which was so annoying that, without exclusion of the right eye from vision, he was incapacitated for his daily duties.

The injured eye showed no signs of irritation; in fact, on first appearance it was apparently normal, but on closer inspection a faint conjunctival scar was seen, starting about 7 mm. below the cornea and to the nasal side of the insertion of the inferior rectus muscle, and extending in a straight line outward for about 2 cm. The field of rotation was not as much diminished as might have been expected, and the defect of motility seemed almost equally distributed. Compared with its sound fellow, the injured eye appeared slightly higher.

I endeavored to find a position of the head and eyes in which there might be fusion of the double images; and discovered that while sitting erect in a straight position facing a small circle of light about level with the eyes, by slightly lowering the chin, and rotating its point to the right, so that the head was inclined to the left at about an angle of 75 degrees, the patient had single binocular vision, that is, there was only one image of the light.

On moving the eyes downward from this point, there was immediate diplopia. The false image appeared lower and on the side of the uninjured eye—crossed diplopia—and the distance between the true and false images increased as the eyes were rotated further downward. When the eyes were directed downward and to the side of the injured eye, there was also an increase of the distance between the images. These findings were indicative of interference of depression and adduction of the right eye and pointed to injury of the inferior rectus muscle.

On rotating the eyes directly upward, the false image appeared higher on the side of the injured eye —homonymous diplopia—and the distance between the images increased as the eyes were further elevated. Still looking upward, and turning the eyes to the side of the uninjured eye there was also an increase of the diplopic separation. This suggested involvement of elevation and abduction of the right eye, and pointed to injury of the inferior oblique muscle.

Treatment.—The patient was quite anxious as to the advisability of operative treatment, which he had been told offered the best means of relief. I noticed that the slight exercise of muscles of the injured eye during the tests was causing an increase in the field of single binocular vision, and I instructed him to keep the blinder off the right eye until the next visit. By this time there was such diminution of the diplopia, that I was able to give him very satisfactory vision with a small amount of prismatic aid. Finally I urged a prolonged trial with a prismatic correction, thus exercising the disabled muscles, before proceeding to advancement. I corrected a small astigmatic defect, which brought vision up to 6/5 in each eye, and incorporated a 2 degree prism, base down, in the right lens, for distance use. This was very satisfactory so long as the eyes were not turned directly downward. For reading and other visual work at close range, I ordered a 4 degree prism, base down, incorporated in the right lens, and a 2.5 degree prism, base in, in the left lens, which also seemed quite satisfactory. After several weeks the patient complained of discomfort with the reading lenses. I wrote to him to try his distance lenses for close work, beginning with their use for short periods, and gradually increasing the length of time in reading with them. He was very soon able to dispense entirely with the reading glasses. Five months after the injury I saw him for the last time. The right eye appeared perfectly straight and level with its fellow. There was no diplopia except in looking directly downward. In the ordinary position of the eyes in reading, a 2 degree prism, base down, before the right eye, seemed to give perfect comfort. I ordered the full correction without any prismatic addition for distance and suggested a small presbyopic addition with a 2 degree prism, base down, right, in glasses for reading and other close work. Since then the patient has been quite comfortable, and except in reading often works without any glasses.

ANASTOMOSIS OF THE URETERS WITH THE INTESTINE.

A HISTORICAL AND EXPERIMENTAL RESEARCH.*

REUBEN PETERSON, M.D.
Professor of Gynecology Post-Graduate Medical School; Assistant Clinical Professor of Gynecology, Rush Medical College; President of the Chicago Gynecological Society.
CHICAGO.

(Continued from page 573.)

If the subsequent history of the successful cases be considered, the operation is placed in a still more unfavorable light. Of the twenty-two recovering, three died later of pyelonephritis and two of uremia after implantation of the second ureter. The post-mortem in one of these revealed a fibrous condition of the kidney whose ureter had been implanted fourteen months before. No autopsy was secured in the second case, but from the similarity of symptoms it is fair to assume that the pathologic conditions were the same as in the first case. In one case it is noted that the kidney was destroyed through stenosis of its ureteral orifice.

Of the eleven surviving cases, there are five with one and six with both ureters implanted. Two of these cases (those of Evans† and Winiwarter) must be excluded from further consideration, because each has a fistula, opening, the one case in the loin, the other in the perineum, and differing only in degree from other intestinal cutaneous fistulæ. Martin's first case, one of exstrophy of the bladder, showed renal infection after implantation of one ureter, as shown by casts in the collected urine. The attempt to implant the second ureter failed, and presumably the urine still escapes over the pubes. In Boari's case, surviving six months with one ureter in the rectum, it is not stated whether urine still passes by way of the anus. The same criticism may be raised in Tuffier's case, which survived two years, with no signs of renal infection. This leaves one case, that of Chaput, which has survived unilateral implantation eight years. Chaput reports (Boari, *l. c.*) that three years subsequent to the operation the presence of urine could be demonstrated in the liquid evacuations. In the communication to me he states that after eight years there are about three liquid evacuations in each twenty-four hours. Evidently the discharges have not been examined with a view of ascertaining the condition of the kidney under consideration.

In one of the remaining cases (Peters') it is stated that as far as can be judged the strained urine is normal both in quantity and percentage of urea. This case has survived ten months with both ureters in the rectum. As far as can be ascertained no such examinations have

er's uretero-rectal anastomosis stands in a class
lf, and will be discussed in connection with my
xperimental work.

xperimental and clinical observations led Tuffier,
rly as 1890, to the conclusion that ascending renal
ction after uretero-intestinal anastomosis could only
prevented by the preservation of the ureteral orifices.
e suggested for exstrophy of the bladder the formation
f a vesico-rectal fistula by an incision in the septum separating the rectum and bladder and the suturing of the vesical and rectal mucosa. Catheters were then to be introduced into the ureters and carried out through the anus by way of the fistulous opening. By dissection of the exstrophied bladder wall a new bladder, smaller in size, was to be formed over the fistulous opening. Frank's operation of vesico-rectal anastomosis, performed by means of his coupler, is practically the same operation by a new technique.

In 1894 Maydl reported two cases of exstrophy of the bladder operated upon by an original method, consisting of the implantation of the vesical trigonum with its ureteral orifices into the sigmoid flexure. The predominant idea of this operation was the preservation intact of the ureteral orifices and their utilization as a means of preventing an ascending renal infection.

In order to ascertain whether this theory is borne out by clinical facts, thirty-six operations performed according to the technique laid down by Maydl have been collected, tabulated, and summarized.

I have ventured to make use of the term "uretero-trigono-intestinal anastomosis" as descriptive of the operation of uniting the vesical trigonum with its ureteral orifices to the intestinal tract.

SUMMARY OF 36 CASES OF URETERO-TRIGONO-INTESTINAL ANASTOMOSIS.

Number of operations		36
Number of operators		16
Operation performed for exstrophy of the bladder		32
Epispadias without exstrophy		2
Exstrophy and adenoma of bladder		1
Incontinence caused by funnel-shaped urethra		1
Sex mentioned in		36
Males	30

Number of cases living and well at end of 7 years		1

The mortality in the thirty-six operations is surprisingly low when it is considered that it is a difficult major operation, and that the list includes the first cases operated upon before the technique had been perfected.

When we compare this mortality with the 33 per cent. mortality accompanying ureteral implantation without the preservation of the ureteral orifices, we are forced to conclude that the explanation lies in the intrinsic dangers of the latter operation rather than a lack of skill on the part of the operators. Without the vesical ureteral orifice eleven deaths in thirty-three cases from rapidly progressive renal infection; with the ureteral orifices intact, five deaths out of thirty-six cases; two, at least, not being due to infection. Unfortunately, we have no detailed description of the causes of death in v. Eiselberg's three fatal cases, except that two died after one and five days.

Only two cases have died from ascending infection, and one of these (Schnitzler) was operated upon extraperitoneally and not according to the technique laid down by Maydl.

Since the operation is applicable chiefly to cases of exstrophy of the bladder, and the majority of cases of this anomaly occurs in males, one would expect the proportion found, of thirty males to six females.

The sphincteric control over the urine is remarkably good, it being reported as poor only in one case.

The six fistulæ resulted, in some of the cases at least, from timidity on the part of the operator to trust to his suturing and to the employment of gauze drainage. They are all reported as eventually closing.

The noting in five cases of gradually disappearing lumbar pains would suggest a possible renal infection from which the patient slowly recovered. It may be more than a coincidence that in one of these cases (Herzel) where lumbar pain was noted, there was subsequent polyuria, a condition nearly always present in chronic interstitial nephritis. However this may be, the number of cases (ten) living and without apparent signs of renal infection, after the lapse of two years shows that renal infection, if present, can not be very severe.

The primary and secondary results of uretero-trigono-intestinal anastomosis are so much superior to those of ureteral implantation without the preservation of the vesical ureteral orifices as to demand always the performance of the first operation in preference to the latter.

In order to cover the entire field of uretero-intestinal anastomosis it only remains to consider the cases where union has to be attained by the formation of fistulæ between the bladder and rectum.

This was first attempted by Loyd in 1851.

LLOYD,[74] 1851. *Exstrophy of bladder; formation of vesico-rectal fistula; death on the sixth day from peritonitis.* October 3, 1851, Loyd operated upon a male, aged thirty years, for exstrophy of the bladder and separation of the os pubis and epispadias. A skein of thread was passed through bladder and rectum and out of anus. Although the silk was removed on the sixth day the patient died soon after of peritonitis. At the autopsy it was found that the thread had passed through the peritoneum, which in this case was reflected low down in the pelvis.

JOHNSON,[72] 1852. *Exstrophy of the bladder; vesico-rectal anastomosis; death from peritonitis.* Johnson performed vesico-rectal anastomosis by Loyd's method on an infant suffering from exstrophy of the bladder. Death resulted in a short time from peritonitis.

HOLMES,[71] 1863. *Exstrophy of the bladder; vesico-rectal fistula by means of pressure necrosis; failure.* Holmes, in a boy with exstrophy of the bladder, endeavored to establish a free communication between the bladder and rectum by special

TABULATED LIST OF THIRTY-SIX CASES OF URETERO-TRIGONO-INTESTINAL ANASTOMOSIS (MAYDL'S OPERATION).

No.	Date.	Operator.	Conditions Demanding Operation.	Sex and Age.	Operative Result.	Site of Anastomosis.	Rectal Drainage Tube.	Sphincteric Control.	Remarks.
1	Nov. 3, 1898.	Allen, D. P. (51)	Exstrophy of bladder.	M., 15	Recovery.	Sigmoid.	Yes. .	April 6, 1900, retains his evanuations from 5 to 7 hours.	Personal communication from Dr. Allen, April 6, 1900. Patient occupies position as dry-goods clerk.
2	 1894	Bergenhem, B. (52)	Exstrophy and adenoma of bladder.	M., 35	Recov.	Rectum..	" .	1¼ years after operation evacuations are every 5 to 6 hr. during the day; twice at night	Attends regularly to business and appears to be in good health.
3	Feb. 21, 1896.	v. Eiselsberg, A. (53)	Exstrophy. . .	M., 31	"	Sigmoid.	" .	3 months after operation retains urine 6 to 7 hours; 3 years afterward perfectly continent.	Twelve days after operation slight infiltration of urine through incision; completely disappeared 6 days later; transitory pains in lumbar region. Well Jan. 23, 1899.
4	July 30, 1896.	v. Eiselsberg, A. (53)	" " . .	M., 8	"	" "	" .	2½ years after operation soils the bed at night, but is continent during the day.	No pain in lumbar *regions*; abdominal fistula shortly after operation, discharging urine and feces; soon closed. Well April 3, 1900.
5	July 18, 1898.	v. Eiselsberg, A. (53)	Epispadias. . .	M., 6	"	" "	.	6 months after opera. sphincter control good.	Epispadias had resisted all other modes of treatment. Well Nov. 1, 1898.
6	Nov. 11, 1898.	v. Eiselsberg, A. (53)	Exstrophy. . .	M., 12	"	" "	.	. . . .	Well April 3, 1900.
7	Nov. 11, 1898.	v. Eiselsberg, A. (53)	" " . .	M., 8	Death.	" "	. . .	. . . .	Died in five days.
8	June 14, 1898.	v. Eiselsberg, A. (53)	" " . .	M., 6	"	" "	. . .	. . . .	Died next day.
9	Oct. 19, 1898..	v. Eiselsberg, A. (53)	Incontinence due to funnel-shap'd urethra	F., 11	"	" "	. . .	. . . .	Died Nov. 11, 1898.
10	Sept. 14, 1896.	Ewald, Carl (54)	Exstrophy. . .	M., 5	Recov..	" "	No. . .	Urine passed involuntarily for a few days only; 2 years afterward evacuations every two hours during day; sleeps 10 hours at night.	No infectious renal symptoms two years after operation. No casts, 1900.
11	 1898	Ewald, Carl (54)	Epispadias. . .	M., 3	"	" "	. . .	Some incontinence while patient was in bed; function reestablished when he began to walk about.	
12	June 28, 1898.	Frank, Rudolf (55)	Exstrophy. . .	M., 16	"	" "	Yes. .	2 months after operation once in 5 hours; sleeps the whole night.	For two or three days bloody urine.
13	Oct. 31, 1898..	Frank, Rudolf (55)	" " . .	M., 16	"	" "	" .	3 to 5 hours during day; 2 to 3 times at night.	For a month leakage of urine through abdominal incision. Well Jan. 12, 1900.
14	May 25, 1897..	Herczel, Emil (56)	" " . .	M., 5	"	" "	" .	2¼ *years after operation* 6 *to* 7 hours; oftener at night.	One *month after operation polyuria* which lasted four months; shortly after operation had an attack of pneumonia, during which he suffered pain in lumbar regions; 2¼ years after operation polyuria still exists.
15	Dec. 20, 1897.	Herczel, Emil (56)	" " .	M., 25	"	" "	" .	6 months after operation every three hours, but sometimes involuntarily at night.	
16	Mar. 9, 1899.	Herczel, Emil (56)	" " .	M., 11	"	" "	" .	1 month after operation 5 to 6 hours; involuntarily at night.	
17	Apr. 23, 1895..	Kryński, L (57)	" " . .	M., 24	"	. . . .	. .	Continence could be more satisfactory.	
18	June 19, 1892.	Maydl, K. (58)	" " . .	M., 20	"	Sigmoid	" .	Good control; able to work.	Pain in lumbar regions; urine bloody for few days. Living in 1899
19	Oct. 1, 1893...	Maydl, K. (58)	" " . .	F., 12	"	" "	" .	Every three hours and the entire night.	Leakage of urine for short time through the abdominal incision; no renal infection. Living in 1899.
20	Jan. 2, 1895.	Maydl, K. (59)	" " . .	M., 7	Death..	" "	" .	. . . .	Died next day of shock.
21	Jan. 20, 1895.	Maydl, K. (59)	" " . .	F., 22	Recov..	" "	" .	2 weeks after operation every 7 hours.	Pain in lumbar region. Well in 1899.
22	Nov. 23, 1895.	Maydl, K. (59)	" " . .	F., 7	"	" "	" .	6 mo after operation every 4 hr.	No trace of renal infection. Well in 1899.
23	July 2, 1897. .	Maydl, K. (60)	" " . .	M., 4	"	" "	" .	3 wk. after opera. every 4 to 5 hr	No signs of renal infection. Well in 1899.
24	Nov. 29, 1897.	Maydl, K. (60)	" " . .	M., 7	"	" "	" .	Satisfactorily.	Abdominal urinary fistula which closed later. Well in 1899.
25	Mar. 24, 1898.	Maydl, K. (60)	" " . .	M., 14	"	" "	" .	3 to 4 hours in daytime; once at night.	One month after operation examination of urine shows no albumin. Well in 1899.
26	June 20, 1898.	Maydl, K. (60)	" " . .	M., 7	"	" "	" .	Satisfactory.	Well in 1899.
27	Nov. 20, 1898	Maydl, K. (60)	" " . .	M. 4½	"	" "	"	1 month after operation 5 to 6 hours.	Well in 1899.
28	 1895	Mikulicz, T. (61)	" "	M., 28	"	Rectum .	. .	Very unsatisfactory.	Death 4 mos. later from pyelonephritis.
29	Feb. 24, 1899.	Nové Josserand, G. (62)	" " . .	M., 5	"	Sigmoid	No. . .	At first incontinence; 1½ mos. after operation, 6 to 10 evacuations in 24 hours,	No sign of any renal infection. Doing well May 17, 1899
30	March, 1897..	Park, R. (63)	Exstrophy and other congenital defects.	M., 4	Death..	" "	" . .	. . . .	Died 55 hrs. after operation; could not be nourished per rectum because of congenital defect; no sign of *peritonitis.*
31	 1896	Rosegotti. (64)	Exstrophy. . .	M., 9	Recov..	" "	. . .	3 months after operation evacuations are 6 to 8 times in 24 hours.	
32	Jan. 27, 1895..	Schintzler. (65)	" " . .	M., 25	"	Rectum..	No. . .	. . . .	[illegible] 1¼ yr. [illegible] rom [illegible] defect. Post *mortem* showed well-advanced pyelitis.
33	 1896	Trombetta. (66)	" " . .	M., 10	"	Sigmoid	. . .	2 to 3 hours in daytime; 3 to 4 times at night.	
34	Feb. 12, 1898	Tuffier, T. (67)	" " . .	M., 15	"	" "	No. . .	4 months after operation 5 to 6 passages in 24 hours.	No signs of intestinal *inflammation.*
35	Dec. 26, 1895.	Wolfler. (68)	" " . .	F., 9	"	" "	Yes. .	After 6 weeks can retain her urine 6 hours; 1½ years after operation 5 to 6 times in 24 times; occasionally soils bed in sleep.	1½ years after operation no signs of renal infection.
36	Jan. 16, 1897..	Wolfler. (68)	" " . .	F., 8	"	" "	" .	1¼ years after operation every 2 to 3 hours; once at night.	Well 1½ years after operation.

screw forceps, which, placed *in the rectum* and bladder, destroyed the intervening tissue by pressure necrosis. The attempt failed, for although the urine passed into the bowel in considerable quantities, a good portion of it still continued to escape above the pubis. So much pain was produced that the rectal opening was allowed to close.

Rose,[77] 1872. *Vesico-vaginal fistula transformed into a vesico-vagino-rectal fistula; death from uremia ten months after operation.* Rose operated upon a woman whose vesico-vaginal septum had been almost destroyed by diphtheritic ulceration. He made a fistula opening 2 cm. above the anus and about 2 cm. in width in the recto-vaginal septum, and prevented contraction by suturing the mucous surfaces of rectum and vagina. The edges of the freshened surfaces of the labia were sewed together and the vagina closed. The patient was able to control the liquid stools, which she passed per anum every two or three hours. She died ten months after the operation from uremia, the nephritis having its origin in the previous attack of diphtheria. The vagina, bladder, and rectum were found perfectly normal.

Keen,[73] 1875. *Vesico-vagino-rectal fistula following typhoid fever; closure of introitus; well twenty-two years afterward.* A woman aged thirty-four, had been left with a vesico-vagino-rectal fistula from severe sloughing after typhoid fever. After a number of unsuccessful plastic operations for the closure of the fistulæ the entire vulvar aperture was closed. The patient defecated, menstruated, and micturated entirely by the rectum. Micturition occurred only five or six times during the day and once or twice at night. The feces did not pass into the bladder. Eleven years subsequent to the operation a calculus was removed from the vagina, with recovery in three or four days. With the exception of the formation of a small fistula, which closed spontaneously, the subsequent history of the patient was entirely satisfactory. Twenty-two years after the operation she remained in perfect health, with no sign of renal infection.

Thiersch,[78] 1881. *Exstrophy of the bladder; formation of recto-vesical fistula; well after eight months.* The patient was a child with a severe exstrophy of the bladder, together with a defective vagina and a bicornate uterus. A communication was made between a newly formed bladder and the rectum through repeated applications of a Samson's bowel-clamp, which produced a necrosis of the recto-vesical septum. The patient recovered, and although she had been passing all the urine per rectum for eight months at the time the case was reported, there was no rectal irritation or excoriation of the parts near the anus. The bladder remained clear of feces.

Novaro,[75] 1890. *Exstrophy of the bladder; formation of a vesico-rectal fistula and new bladder; recovery; operation a failure.* Novaro, in a girl, aged three, suffering from exstrophy of the bladder, exposed the anterior wall of the rectum by a semilunar incision at the inferior border of the vaginal orifice. By a plastic operation he united the dissected wall of the bladder to the rectum, which had previously been opened 12 to 15 cm. The raw surface of the bladder was covered in by the freshened labia majora. The edges of the flap sloughed and allowed the urine to escape over the pubes. At the time of the report Novaro intended to form a cloaca by a supplementary plastic operation.

Tuffier,[79] 1891. *Formation of recto-vesical fistula; partial success.* Tuffier established an artificial recto-vesical fistula with partial success, a fissure remaining which he intended to close later. The patient remained well. The urine passed by way of the rectum, could be held ten minutes.

In the 1899 edition of Duplay and Reclus, Tuffier, while mentioning the technique, does not report the case or give its subsequent history.

Resegotti,[76] 1895. *Exstrophy of the bladder; formation of vesico-vagino-rectal fistula and closure of introitus; death from pyonephrosis.* By a plastic operation in a case of exstrophy of the bladder, Resegotti formed a bladder out of the abdominal wall and the labia majora and minora. An artificial vesico-vagino-rectal fistula was then made and the introitus closed. Complete continence ensued, the urine being passed voluntarily per anum every two or three hours. Double pyonephrosis soon developed, from which the patient died. Resegotti condemns the formation of communications between the intestine and the urinary tract.

Gallet,[69] 1896. *Formation of recto-vaginal fistula and closure of introitus; success.* A case is briefly mentioned by Gallet where, for a vesico-vaginal fistula, he closed the vagina and made an opening in the vagino-rectal septum. The patient did well and was able to control the urine two hours.

Halstead,[70] 1900. *Exstrophy of the bladder; vesico-rectal anastomosis with the Frank coupler; death from shock.* Through the kindness of the operator, I am permitted to report the following unpublished case:

The patient was a boy aged 5 years, suffering from exstrophy of the bladder and other congenital defects. Jan. 9, 1900, the abdominal cavity was opened and the sigmoid attached to the serous surface of the posterior aspect of the ectopic bladder wall by sero-serous quilted sutures. The bladder-wall was next incised 1.75 cm. in a longitudinal direction just above the ureteral openings, and one-half of a Frank coupler introduced. The other half of the coupler was inserted into a longitudinal incision in the sigmoid. The adjacent edges were united by a series of quilted sutures. By a plastic operation a new bladder was formed over the coupler and the defect in the abdominal wall nearly closed. Child urinated several times during night through rectum. Died at the end of sixteen hours of shock. The post-mortem showed no evidences of peritonitis. No escape of urine through sutured bladder-wall. Rectum contained nearly one ounce of urine. Right heart dilated.

It is unjust to include the cases of Loyd, Johnson, and Holmes in any consideration of vesico-rectal anastomosis as a treatment for exstrophy of the bladder, since the methods employed were exceptionally crude. The same may be said of Thiersch's case, although the patient was well at the end of eight months.

Halstead's case, where Frank's technique was employed, demonstrates the operation to be perfectly applicable to human beings. Frank's interesting experiments have shown that in dogs vesico-rectal anastomosis is a comparatively safe procedure; that the bladder remains free of feces, and that infection of the kidneys does not result in some of the cases operated upon. These findings are confirmed by the results of my own experimental work, which show that whenever the ureteral orifice is left intact, for a certain time there may be freedom from infection, even where that orifice continually comes in contact with virulent micro-organisms.

Of the five dogs reported on by Frank, the first three were examined fifteen, four and sixteen days respectively after the operation. The first two showed signs of renal infection, but the third showed two small foci of round-celled infiltration. The other two dogs were killed and examined twenty-seven and ninety-one days after the operation. In both cases there were unmistakable evidences of ascending renal infection. In other words, the longer time elapsing after the operation the more changes resulted in the kidneys.

How great this infection will be and to what extent the animal can overcome its infection can only be shown by allowing the animals to live a longer time before making the examinations. This Frank promises to do, and the results will be watched with great interest. The burden of proof, however, remains with him to show that renal infection after his operation is impossible or at least rare. Until such proof be forthcoming Frank's prediction that vesico-rectal anastomosis will become more popular than gastro-enterostomy will hardly be fulfilled. The question of infection must be definitely settled before other virulent micro-organisms are given admittance to a bladder already handicapped by disease.

(To be continued.)

Clinical Reports.

ACUTE TEMPORARY DILATATION OF THE HEART ACCOMPANYING THERMIC FEVER.

REPORT OF TWO CASES.

C. F. CLOSE, M.D.

CHICAGO.

Acute dilatation of the heart has been described as occurring under various conditions, chiefly as a result of excessive physical exertion. So far I have found no report of a case in connection with sunstroke or heatstroke—*Hitzschlag,* as the Germans more exactly express it. The following two cases occurred during the excessively hot weather of the past summer.

Case 1.—A male, aged 17, born in America, of Danish parentage, and a photographer's assistant, had always been healthy. There was no constitutional disease in the family. The patient's occupation compelled him to work under a partially unprotected skylight the greater part of the day, where the heat was very intense. I was summoned soon after the attack of sunstroke, and found him suffering with the usual symptoms:

high temperature; rapid, feeble pulse; headache and dizziness; marked congestion of the vessels of the head and neck. He did not lose consciousness. The heart was found to be greatly enlarged in all its dimensions, but especially to the right, reaching to the right border of the sternum. The pulsations were very noticeable in the epigastrium just below the arch of the ribs. The sounds were very low and somewhat indistinct. A mild systolic murmur was heard over the tricuspidal valves. Under the ordinary treatment—recumbent position with elevation of and ice compresses to the head; cathartics, etc.—he recovered rapidly, and ten days afterward the heart had subsided to its usual, *normal*, boundaries.

Case 2.—A female, aged 23, unmarried, an American of German parentage, worked as teacher for a sewing-machine company, her business being to go from house to house where machines had been sold, and instruct the inmates in their use. This necessitated her being out the greater part of the day. During one of these trips she was overcome, on the street, by the heat and lost consciousness. When I arrived she complained of great dizziness, pain in the head, and was somewhat dyspneic. She presented practically the same symptoms as the preceding patient, and had been under my care some time before for catarrhal bronchitis, etc., so I was quite familiar with her condition, and the result of the examination of the heart was a great surprise to me. Formerly it had been absolutely normal, but now I found the dulness increased in all directions, but chiefly to the right as before, reaching slightly beyond the middle of the sternum. The sounds were somewhat muffled, but no murmurs. The pulse was rapid, and of low tension. As before, the patient recovered gradually, though not so rapidly. In two weeks the heart had gone back to its former dimensions, and aside from some dizziness and sensitiveness to the sun, she was as well as ever.

I have been able to keep both of these patients under observation since the attacks, and neither has shown any symptoms of "weak heart" since, nor had they before. Both are actively employed at work which throws some strain on the heart. I am inclined to believe that the cause of this acute dilatation may be looked for in the nervous system, and that it is a part of the general muscular relaxation the result of profound shock. Added to this we have a general venous congestion which especially overtaxed the right ventricle.

4707 Evans Avenue.

RUPTURE OF THE MEMBRANA TYMPANI FROM INDIRECT VIOLENCE.

WITH CONCUSSION OF THE LABYRINTH AND COMPLETE DEAFNESS.

RICHMOND McKINNEY, M.D.
LARYNGOLOGIST TO THE EAST END DISPENSARY.
MEMPHIS, TENN.

On Oct. 29, 1900, there came to my service at the East End Dispensary, a negro man, aged 23, with the following history: At two o'clock in the afternoon of October 28, a man had slipped up behind him and struck him a heavy blow on the right side of the head with a wagon-wheel spoke. For at least a half hour following this he lay senseless, and when he came to and arose to his feet he felt, as he described it, "foolish." Blood was flowing from his right ear and likewise from his mouth. This discharge of blood continued at intervals for some time. The evening of that day he had, as he judged from his sensations, a high temperature.

When I saw the patient on the afternoon of the day following, I found the drum membrane of the right ear to be in this condition: The entire membrane, with the exception of the membrana flaccida, was congested, it being especially red along the lower border, this probably being due to blood stasis in this portion of the membrane. The handle of the malleus was even more congested than the surrounding membrane. In the posterior half of the membrane was a perforation running for almost two-thirds of its diameter. This perforation was not gaping, and was *perfectly straight.* Bone and air conduction were both entirely absent, the patient being completely deaf in this ear. There was no tinnitus. I append a drawing of the injured membrane.

After cleansing the ear, I inserted a strip of iodoform gauze, and instructed the patient to go home, remain quiet, and return the next day.

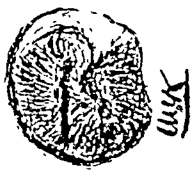
The following morning he again presented himself, and stated that the night before he had again experienced the sensation of high temperature, and continued to spit blood. After cleansing the ear I found that the discharge of blood from the wounded membrana had ceased. There was still, however, *total inability to hear in this ear.* The patient desired to go to work, but was instructed to return home and to refrain from any unnecessary physical exertion.

When next seen, on November 2, the perforation in the drum had entirely healed. Deafness was as marked as ever. He at intervals had continued to spit blood.

At this writing—November 20—the patient has returned to work with a practically perfect drum, but is still stone deaf in the affected ear. The expectoration of blood has wholly ceased.

Although cases of traumatic perforation of the membrana tympani from both direct and indirect violence are not of great rarity, still there are some features of this case which render it of more than passing interest.

As one of these, may be mentioned the continued expectoration of blood, and high temperature, which might lead one to believe that in this case there was a fracture of the base of the skull. The manner and force with which the blow causing the injury was used would also lead to the opinion of a graver lesion. But this has been excluded, I should think, by the subsequent history of the case. Another interesting feature is the evident concussion of the labyrinth, with marked and permanent deafness following. But the most unusual and peculiar feature to me in this case was the fact that the rupture of the drum occurred in transverse relationship to the fibers of the membrana, and was perfectly straight and not oval and gaping as usually is the case in lesions of this membrane from indirect violence.



It is unfortunate, as concerns the hearing, that the therapeutic resources of the aurist do not permit him to close his reports of such cases as this with the gratifying words *restitutio ad normalem.*

Lyceum Building.

Intrarectal Urethra for Exstrophy of the Bladder.—Soubbotin, of St. Petersburg, has cured a case of exstrophy of the bladder by a method described, in the *Semaine Méd.* of January 23, as extremely satisfactory in the one case in which he has had occasion to use it. Through a Kraske posterior incision the rectum is isolated from the side and two longitudinal incisions made in it. The fundus of the bladder is manipulated so as to bring the ostium of the urethra into one of these slits, where it is sutured. Two longitudinal incisions are then made below this point to the anus, and the edges of the flap thus obtained are sutured together above, thus providing a tube running from the urethral sphincter to the anus—an intrarectal urethra with its own sphincter and the anus intact below.

EXSTROPHY OF THE BLADDER.

F. GREGORY CONNELL, M.D.

ADJUNCT PROFESSOR OF SURGERY, COLLEGE OF PHYSICIANS AND SURGEONS,
MEDICAL DEPARTMENT, UNIVERSITY OF ILLINOIS.

CHICAGO.

[*Awarded Senn Medal at the Fifty-First Annual Meeting of the American Medical Association, June 6, 1900. Received by the Committee, March, 1, 1900.*]

EMBRYOLOGY.

Before considering a congenital deformity of the bladder, it will be advisable to review briefly the embryological development of the genito-urinary system, and, of necessity, the embryo as a whole.

The ovum, a single cell with a single nucleus, soon after impregnation becomes, by karyokinesis, a mass of cells resembling in shape and appearance a mulberry, hence the name, morula. A clear fluid next accumulates in the center of this mass of cells; at first small, but gradually increasing in amount. Thus, the morula is converted into a globular vesicle, termed the blastodermic vesicle, the wall of which is at first composed of a single layer of cells—ectodermal, but later, a second layer of cells—entodermal—is completed. This double layer of cells is termed the blastoderm.

The first result of the segmentation of the ovum is the formation of the blastoderm and the disposition of its cells into the embryonic layers. At this time is seen the development of the area germinativa or embryonal area, by the accumulation of cells at a limited point on the inner surface of the blastodermic membrane. It is from this area alone that the body of the embryo is developed. The remainder of the germ forms what is termed the extra-embryonic structures, such as amnion, chorion, and yolk sac. In this germinal area there is seen an opaque line called the primitive streak. In the streak develops a groove, the primitive groove, bordered by two ridges, which will become dorsal plates, and, ultimately uniting, inclose a cylindrical space, the tubus medullaris, or the nervous system.

On cross-section, at this point, there will be seen a marked accumulation of cells between the ectoderm and entoderm, most noticeable on each side of the anterior extremity of the primitive streak. This is the third germ layer, the mesoderm.

The mesoderm at an early stage consists of four parts, two on each side: one near the medial line called the paraxial mesoderm—primitive segmental or vertebral plate—and a lateral plate on each side. The paraxial mesoderm undergoes transverse division into cubical masses, called mesoblastic somites or primitive segments. The lateral mesoderm splits into two layers: 1, outer-parietal or somatic mesoderm; and 2, inner-visceral or splanchnic mesoderm. The somatic mesoderm uniting with the ectoderm is called the somatopleure. The splanchnic mesoderm uniting with the entoderm is called the splanchnopleure.

The cavity existing between the splanchnopleure and the somatopleure is the celum, body-cavity, or pleuroperitoneal cavity, which will ultimately become subdivided into the great serous cavities of the body—pericardial, pleural and peritoneal. The germ, or germinal area, at this stage of its development, has the shape of a hollow sphere or vesicle. The differentiation of its cells into epiblast, endoblast, and mesoblast, has taken place. The foundation for every structure of the body is well under way and in tangible shape. The further growth and development consists chiefly in an unequal growth of the different parts; in evaginations and invaginations; the furrowing and constricting off, of certain areas.

In considering the further history of the development of the embryo, the mesoblast alone will be considered, excluding the other structures, because of their lack of close connection with the subject. The primitive segments are intimately associated with the development of the spinal column and muscles of the back; hence they will not be included in this review. The lateral plates have split into the somatopleure and splanchnopleure, between which is the celum or body cavity. The future development of these two structures is of paramount importance in an effort to arrive at a thorough understanding of exstrophy of the bladder.

In the earliest stage, the embryo lies flat on the surface of the yolk, as a watch-glass, and is not distinctly differentiated from the adjacent blastoderm. The cavity of the germ is one undivided space. But there soon appears the head-fold and tail-fold, and likewise similar lateral folds as if by an invisible constricting band which was gradually drawn tight until the large single cavity of germ has been divided into two spaces of unequal size. The smaller, or intra-embryonal portion formed the gut-tract, and the larger, or extra-abdominal division constituted the umbilical or vitelline vesicle, or yolk-sac, these two cavities uniting at a point which is to become the umbilicus and communicating by means of a short canal, the vitelline or omphalo-mesenteric duct. These lateral downward folds of blastoderm are called visceral plates, and consist of the splanchnopleure internal and somatopleure external. The splanchnopleure descends from each side, meets in median line and, coalescing, it pinches off a portion of the yolk-sac, which is to become the gut-tract and is enclosed in the body cavity by the descending and coalescing walls of somatopleure. Hence the splanchnopleuric fold outlines and forms the intestinal canal. The somatopleuric layer, which accompanies or rather follows the splanchnopleure, constitutes the lateral and ventral body wall of the embryo, by fusion in the median line, except, of course, at the umbilicus. Failure of these somatopleuric folds to unite in the median line is the cause of various deformities, not the most infrequent of which is exstrophy of the bladder.

The allantois must be considered, as it is from this embryological structure that the bladder is formed. It is an evagination of the splanchnopleure, the gut-tract, the same as is the pancreas, liver and lungs. It sprouts from the hind gut, at about the same time that the amnion is being developed; it is, at first, solid and pear-shaped, but soon becomes vascular and membranous. It projects from the body, through the imperfectly closed anterior abdominal wall, into the cavity of the amnion and into contact with the false amnion, where, by uniting with the vascular system of the mother, the placenta is developed.

Bischoff, Reichert, Remak and others, claim that the allantois is of double origin, arising as two separate and distinct columns of cells, either solid or hollow, from the neighborhood of the Wolffian body, and soon coalescing. This order of events has been observed in some of the lower animals, but not in man. A human embryo of three weeks has been described, with a perfect single allantois. The allantois is the chief agent of the early circulation; it contains two arteries and two veins. The arteries are, at first, branches of the abdominal aorta, but subsequently, when the primary aortæ coalesce, they become branches of the hypogastric arteries.

In the mammals, the extra-embryonic portion of allantois contains no cavity. At about the third month it is no longer of use and its extra-embryonal portion becomes the umbilical cord, its vessels becoming umbilical vessels.

Its intra-embryonic portion is divided into three subdivisions: 1. The upper, the urachus, at birth is an atrophied cord extending from fundus of bladder to umbilicus. 2. The middle third becomes the urinary bladder. 3. The lower third becomes, in males, the first part of urethra; in females, the entire urethra. The proximal portion of the allantois, that is, the part intervening between bladder and intestine, is designated as the "sinus urogenitalis," while the caudal end of intestine, which is in effect a pouch in which both allantois and intestine terminate, is known as the "cloaca."

During the sixth week there appears on the surface of body, in the region corresponding to position of the cloaca, the cloacal depression, or proctodeum, which extends upward, forming the communication between gut—entoderm—and skin—ectoderm.

In amphibia, reptiles and birds, also in the lowest mammals, the monotremata, the cloaca is a permanent structure. In all mammals, except the monotremata, the cloaca undergoes division into a posterior or anal canal and an anterior or urogenital aperture, opening independently on surface of body; the latter in the female is the short urethra and fossa of vestibule, and in the male is the prostatic portion of urethra. This division is brought about by three folds, one from each side and one from the point of union of urogenital sinus and intestine. These folds coalesce about the tenth week and at the time of birth constitute the perineum.

The embryology of the ureters must also be considered, not only because of their intimate relationship to the bladder, but also on account of their participation in the most modern methods of treating deformities and certain diseases of the bladder. The ureters spring from the lower end of the Wolffian duct, as an evagination or budding, just before it enters the cloaca. The Wolffian duct is the first trace of the urinogenital apparatus to appear in the embryo. At first, it is a longitudinal column of cells, situated between the vertebral plates and the lateral plates and soon becomes hollow, its hind end uniting with and opening into the cloaca. Its upper end is connected with the pronephron and mesonephron, and is not open. Both of these organs, in mammals, disappear before birth, and the Wolffian duct becomes, in males, the vas deferens, and in females, a remnant known as Gärtner's ducts. The ureter springs as a bud from the Wolffian duct, ascends through a mass of mesoblastic tissue, called metanephric blastema, to the metanephron, or permanent kidney. Here, collecting-tubules from the ureter grow out and become continuous with masses of cells of the metanephric blastema, which then differentiate themselves into kidney tubules. At first, the ureter and Wolffian duct communicate by a common opening, with the intestine, so forming a cloaca, but this state of things lasts for a short time only. Owing to alterations brought about by processes of unequal growth the orifices of the ureters subsequently change their position, so as to open separately into the urogenital sinus, and still later by the further operation of the same agency, they come to open into the bladder, on its dorsal wall, thus gradually assuming their permanent location.

This cloacal stage of the development of the excretory apparatus has its counterpart as a permanent and normal structure in some of the lower animals. It has been held as a general principle that the higher animals, in the course of their embryological development, repeat, to a greater or less extent, the form of the lower members of the class to which they belong. This principle is well brought out by Gadow, in his work on "The Cloaca and Copulatory Organs of the Amniota." He describes in detail these organs in the crocodilia, sauria, ophidia, aves, chelonia, monotremata, marsupialia and placentalia. He shows the gradual tendency toward the separate openings: one for the fecal current, and another for the genito-urinary secretion, as is found in man. It will be seen from his work that the natural cloaca is quite different from the artificial cloaca, as made by surgeons after implanting the ureters into the rectum.

In the animals in which it exists naturally the cloaca is subdivided into three compartments: 1, proctodeum, or external portion; 2, urodeum, or middle portion, urogenital; and 3, coprodeum, or inner portion, the fecal pouch. The middle segment, urodeum, is separated from the division above and below by folds of mucous membrane which do certainly serve as more or less of a protection. The ureters open at the summit of a papilla, and in many instances there exists a receptacle similar to a bladder, which communicates with the rectum. From this it will be seen that the kidneys are protected much more perfectly in these cases than are the same structures in man when the ureters are made to communicate artificially with the rectum. Then also, the consideration of the normal cloaca may evolve a solution of the question: "As some of the lower animals, and birds, have the bladder and rectum in one cloaca, why can not human beings live comfortably in the same condition?"

In attempting to answer this question, there are many explanations which might be advanced, all of which are lacking in the one essential, that of being conclusive. The urine of these animals might be antiseptic. The feces of these animals might be sterile or non-infectious. But that such is not the case has been demonstrated conclusively. Or, it might be said that, owing to the traumatism accompanying the implantation of the ureters into the rectum, the manufacturing of a cloaca, a *locus minoris resistentiæ* is established, which renders the danger of infection of these parts more likely to occur—a condition that is never present in a natural cloaca.

Van Hook answers this question, and says: 1. The urine of birds is very slightly moist; hence it can not mechanically carry bacteria to the kidneys, as is the case with fluids. This point is not of practical importance, as micro-organisms extend into solid as well as liquid media. Also, infection has not followed in animals with a natural cloaca where the urine is liquid. 2. Birds' ureters are supplied with mucous membrane, evolutionarily accustomed, as it were, to contact with infected solids and fluids. This seems to be the only rational explanation, and it also explains the fact that the liver, pancreas, salivary glands, the middle ear and Bartholin glands do not, as a rule, become infected from the more or less septic canal into which they open.

MALFORMATIONS.

Those organs which are placed in the median line of the body are more subject than the extremities to certain deviations from the normal development. The structures which have a more complicated mechanism and those which are formed latest in the stage of development of the embryo, are naturally more apt to be interfered with than those the formation of which is more simple and earlier in the history of the fetus. The bladder is formed late, and owing to its position in the median line—this being formed by the fusing of the visceral plates, which are comparatively complicated and also late in development—is frequently the seat of defective development, causing various malformations, some of which are consistent, and some inconsistent with life, some remediable by surgical means, and some not. A failure to complete the anterior wall of the trunk is not an uncommon defect, as is seen in cases of thoraco-gastro-schesis, thoraco-schesis, and gastro-schesis or fissura abdominalis. The latter is seen in different varieties: 1, extending the entire length of linea alba; 2, congenital hernia funis, at umbilicus; 3, closed at umbilicus, defect above; 4, closed at umbilicus, defect below. As a rule, Class 4 is associated with exstrophy of the bladder. The most common deformity of the bladder is

1. Exstrophy of bladder. Other malformations are:

2. Absence of bladder. When this exists it is almost universally associated with absence or imperfections of other important organs or structures, rendering life an impossibility. The condition is extremely rare, the organ usually being represented by a small overlooked pouch or rudiment. One interesting case is recorded by Fleury, in which the ureters opened directly into the urethra, and the girl lived to the age of 16 or 17 years. A post-mortem was held and no trace of a bladder could be found. Benninger reports a similar case. Bonn records a case in a new-born child in which kidneys, ureters and bladder were absent. Gross reports a case of marked arrested development in which the ureters ended in the gut near its termination, with imperforate anus, and the large bowel absent. A similar case was noted by Meyer. Under this heading might be included the peculiar case of Richardson; and, according to Chance, a case resembling Richardson's has been observed by Camper. Wytterhoeven reports a case of atrophy which was mistaken for absence. There existed a uretero-vaginal fistula for thirty years, causing the shrinking of the bladder to the size of a pea.

3. The opposite condition, that of multiple or supernumerary bladder. This is likewise one of exceedingly rare occurrence. Before we diagnose a multiple bladder, each bladder must be found to have its separate ureter, and all coats demonstrated. Many of the so-called multiple bladders are in reality merely sacculations or herniæ of the bladder. The following have been reported: Blasius found a double bladder; A. P. Smith, double bladder; Scibelli, triple bladder; Molenette, five

bladders, six ureters and five kidneys. Sacculation of bladder and bilobed or multiple bladder are frequently acquired, and not congenital conditions, due to pathological changes in the bladder wall or interference with escape of urine, as in prostatic enlargement or stricture of urethra, or due to enlargement of a certain portion of the mucous membrane. It is claimed by some authors that the bladder originates from a double allantois, which owing to arrested development might cause a bilobed bladder. A case is mentioned by Heyfelder in which the septum was almost complete. Holmes describes a cyst which might have been in all probability a hernia.

4. Imperforate bladder or atresia of urethra. This condition is very rare. Cases are on record which have been associated with exstrophy, and hence are doubtful.

5. The posterior wall of bladder may be the site of the malformation, and the bladder communicating with the pelvic cavity, vagina or rectum. This form is unusual.

6. Both the anterior and the posterior wall may be defective. This condition is still more exceptional.

The urachus is often the seat of arrested development: 1, failure to obliterate at any point, giving rise to a urinary fistula opening at the umbilicus; 2, it may close at both ends, forming a cyst, which may be subdivided into smaller cysts; 3, it may close at peripheral extremity, but the remainder be unobliterated and communicating with the bladder; 4, it may close at visceral end and the remainder being open will cause a sinus at the umbilicus.

The abnormalities of the ureters consist of the following:

1. Double ureters are the most common, both of which may terminate normally in the bladder; both may terminate abnormally, or one may end normally and the other abnormally. Again, the double ureters vary in shape. Two distinct pelves, with the ducts uniting at any point on their way to the bladder, may enter that viscus through a single orifice. They may remain entirely separate throughout their course; or a single pelvis may divide into two. Complete duplicature has been reported by Chance, Schneider, Erlach, Ramsey and others.

2. Absence of ureter is extremely rare. Cases have been reported by Förster and Bartels.

3. Abnormal termination of ureter may exist by opening into a male genito-urinary organ, namely, bladder; prostatic portion of urethra; seminal vesicle, ejaculatory duct, vas deferens. In the female, the termination may be into the bladder; vagina; vestibule, urethra, under hood of clitoris, and Gärtner's duct. Open termination into the rectum is extremely rare. Such cases have been reported by Richardson, Camper, Simon, Gross and Meyer. Blind termination of ureter may exist as cystic dilatation; or no dilatation, associated with absent or atrophied kidney.

4. Congenital flexure of ureter may occur with no signs of inflammation, and after releasing the flexure, the fluid escapes easily.—Weigert. These conditions are in frequent association with other deformities.

An explanation of the anomalies of the ureter is given very clearly by Fenger. "If the ureter does not separate from the Wolffian duct, but remains a branch of the latter, the ureter will terminate in the seminal passages in man, and in woman in Gärtner's duct. If the ureter separates from the Wolffian duct, but does not move up into its normal place in Lieutaud's triangle, we will have an abnormal termination, low down in the prostatic portion of the urethra. If ureter separates from the Wolffian duct without emptying into a hollow organ, a blind termination results. If the ureter, instead of moving forward into the anterior portion of the cloaca, remains at its original location in the posterior portion, we find the termination of the ureter in the rectum. Double ureters originate either as a double branch from the Wolffian duct or as a single branch, which later divides."

The condition of exstrophy of the bladder includes, as a rule, all the cases of gastro-schesis in which the fissure is in the lower part of the abdomen. It is seen in different varieties or degrees of the same variety: 1. There may occur no fissure in either abdominal or bladder wall, but an absence of symphysis, with hernia of the bladder.—Mayo. 2. The bladder wall is perfect and protrudes through abdominal fissure or the umbilicus.—Vrolik. To this condition the term "ectopia vesicæ" has been applied. 3. The ordinary form is fissure in both abdominal and vesical walls. This form has been subdivided by Winkel as follows: Fissura vesicæ inferior, or closed symphysis with defect below; fissura vesicæ superior, or closed symphysis with defect above; absence of abdominal wall, of anterior bladder-wall, of symphysis pubis with cleft of external genitals. This last division he calls "eversio et ectopia vesicæ." 4. Anterior and posterior walls of the bladder may both contain a fissure, and thus occur in two halves, separated by an opening of the intestinal tract.—Bartels, Retzius, Friedlander, Rose, Frænkel, Meckel, Vrolek, Fœrster, Dietrich.

To the ordinary form of this defect many names have been given: ectopia vesicæ, ectropium v., ecstropia v., extroversio v., inversio v., eversio v., fissura v., eversio et ectopia v., exstrophy of the bladder, and congenital hiatus of bladder.

The term "exstrophie" was first applied by Chaussier, in the year 1780, and has been almost universally adopted at the present time. The words "ectopia vesicæ" have been generally accepted as indicative of that rare condition described by Vrolik in which the anterior wall of bladder is not defective.

In the common form of exstrophy the clinical picture is so very characteristic that if the treatment was as easy to carry into effect as the diagnosis is easy to arrive at, the history of this affection would not be such a sorry one as regards results in attempts at correction. Extensive fissura abdominalis occurs in females almost entirely. Exstrophy of the bladder occurs with much more frequency in the male. Of 68 cases collected by Mr. Earle in 1828, 60 cases were in males and 8 in females. Holmes in his experience found none in females. Sir H. Thompson reported 8 cases, 2 in females. McWhinney mentions 7 males and 2 females. Phillips collected 21 cases in females. Braxton Hicks reported 14 in males, 2 in females and 4 doubtful. Geoffrey St. Hilaire found one-fourth of the cases in females. Duncan says this condition is found "more often in males because the generative organs are more complex. It has been pointed out that deficiencies in anterior median line occur most frequently in the male. Deficiencies in posterior median line occur with more frequency in the female sex." These cases were frequently mistaken for hermaphrodites; or else male children were considered to be females. In 1808, Soden reported a case of exstrophy which is of interest, as it shows with what difficulty the sex of the individual has been decided on in some instances. The patient, 24 years of age, wore a skirt and was baptized Sarah L——. After examination by three medical men, Sarah was pronounced a male. In 1860, Buck and Coote wrote in the *Lancet,* under the title, "A Short Account of the Post-Mortem Examination of the Body of a Person Who for 73 Years Passed for a Female; Congenital Malformation of Penis, Scrotum, Testes and Pelvic Bones with Complete Absence of the Urinary Bladder." One explanation of the discrepancy in the proportion of occurrence in sexes, is that, cases in the female were not recorded. Owing to the natural modesty of the sex, there was less of an inclination to let the matter become known. As misleading features, might be mentioned the dress, usually that of a female; small testes lost in large labial folds of skin; the width of hips, causing the waddling gait, which is an exaggeration of the female gait; and the feminine mode of micturition, in those cases in which the urine is retained for a short space of time in the dilated ureters.

This deformity is not incompatible with a comparatively long lease of life, and even in some cases with the power of reproduction. In the male the sexual potentiality is usually absent, if not sterile, the abnormality rendering him impotent. In the female conception and delivery is sometimes possible, as in cases recorded by Huxham and Bonnett, Thiebault, Ayers, and Hamilton. Many of these cases die in infancy, but judging from the literature, the majority reach adult life, and cases are on record in which the age of 40, reported by Bartholin; 46 and 49, by Quatrefages; 71, by Flajain; 73, by Coote, and 80 years, by Hamilton, have been reached.

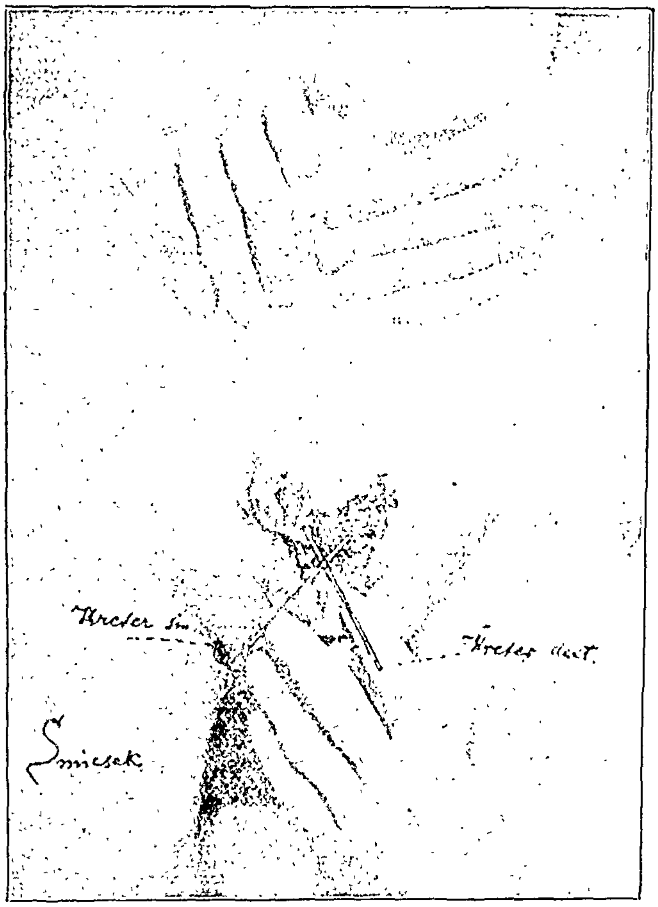
The patient is usually seen during infancy or childhood, with a tumor presenting in the median line of the hypogastrium, at the site of the mons veneris.—See Fig. 1. This tumor is a red vascular, round or ovoid projection, which has at different times been mistaken for hernia, nevus and malignant tumor. Frequently this mucous eminence is divided into two, by a longitudinal narrow ridge, extending from top to bottom. This bilobed appearance was noticed by Champney, Chaussier, Breschet and St. Hilaire. It has been pointed out as a factor in favor of the theory that the bladder arises in two halves, which ultimately unite. This condition is one step in advance of those cases reported by Bartels, Rose and others, in which the bladder has not united and was in two halves, the halves being separated by an abnormal opening of the intestine.

This elevated mass is, in reality, the mucous surface of the posterior bladder wall, which protrudes where the anterior bladder and abdominal walls are absent. This defect in the anterior wall of the bladder was formerly described as a cleft. Tenon, in 1761, observed and placed stress on the point that all of the anterior wall was wanting; that, as a matter of fact, but little more that the trigone remained. The degree of elevation depends on the intra-abdominal pressure. The recti muscles being separated, there is present a weakness in the abdominal wall at this location, a ventral hernia, as it were. Similar to other hernias, this swelling decreases or increases in size and volume, in accordance with the position and the movements of the patient. When standing it is more marked that when lying down and when straining, such as in coughing, sneezing, crying, defecating, etc., it becomes much more prominent.

The size of this swelling varies. In infants it is usually no larger than a walnut, but with advancing years it increases, and in adults may attain the size of a fist, from 2 to 3 inches long by 4 to 5 inches wide (5 to 8 by 10 to 12 cm.). The color is usually of a bright-red and is almost constantly varying slightly, owing to the external agencies which are always irritating this tender surface. At the edge of this mass, the margin where the mucous membrane passes into epidermis, is seen a boundary line or zone of smooth bluish tissue, such as is seen at the edges of the fissure in cleft-palate and hare-lip. In some cases this edge presents a margin of dense contracted connective tissue, evidence which has been claimed by some as a prenatal attempt at repair and cicatrization on the part of nature. The surface, as said above, is composed of mucous membrane, the "stratified, squamous or transitional" type of epithelium. The mucous membrane, as a rule, retains its characteristics and does not change as much as would naturally be expected, but persists as mucous membrane for many years, notwithstanding its location on an exposed part of the body, where mucous membrane is not found under normal conditions.

As bearing on this point, there might be mentioned the case operated on by T. Smith, in which he transplanted the left ureter into the colon. Afterward he noticed that the left side of the exposed mucous membrane of the bladder underwent a change in appearance, "having become much lighter in color and somewhat cutaneous in character." That this exposed mucous membrane is kept continually moist may be the reason for its persisting as such. It is strange that in his case the urine from the right ureter should not have exerted an influence on the left side; for in the ordinary cases of exstrophy, a large portion of the mucous membrane is above the ureteral orifices; yet it maintains the characteristic features of mucous membrane. In the young it is tender and may bleed profusely on slight provocation. but soon becoming somewhat accustomed to the circumstances in which it finds itself, its vascularity diminishes and the surface becomes quite tolerant of the unavoidable irritation, and the wall becomes quite hypertrophic. From the surface, usually at its lower portion, is observed the escape of the urine, which may dribble away almost constantly, or be expelled in small jets at irregular intervals. If in jets, it is almost certain that the ureters are more or less dilated. The ureters in many cases are dilated, as is also the pelvis of the kidney. Cooper mentions an instance where the ureter was larger than the rectum. Mörgelin reports a similar condition. Petit cites an instance where the dilatation was to an extent of 2 inches in diameter. Thilow relates finding the ureter very large, and Oliver reports a case of the ureter being as large as a child's intestine. Meckel says the ureters are often found dilated in other varieties of congenital deformities, as, for instance, in a case of an acephalous monster, in which the genito-urinary apparatus was otherwise normal. He claims that this dilatation of ureter might be due to some cause other than obstruction.

PLATE I.



Exstrophy of Bladder. (After Herczel.)

The course of the ureter in exstrophy is somewhat altered from that taken under normal circumstances. The cul-de-sac between the rectum, or uterus, and bladder is greatly enlarged inferiorly and anteriorly, owing to what is practically an absence of the bladder from the pelvic cavity. They enter the bladder from below, after descending into this deep cul-de-sac, and then ascending to the bladder. Normally, they descend comparatively straight from kidneys to bladder.

On close examination, it will be seen that the urine makes its exit from two small pyramidal prominences: at the apex of each will be found a larger or smaller opening which is the orifice of the ureter. It will be noticed frequently that there is no umbilicus; if present, it is only a flat pigmented spot. This absence gives to the abdominal wall above the exstrophy a most peculiar appearance.

Wood calls attention to the crescentic border of cicatricial tissue to be felt and seen immediately above the tumor mass, which he considers to be the upper or omphalo-mesenteric portion of umbilicus. A case is on record by Champneys where the umbilical cord was divided in two just before reaching the child's body; and another case by Dietrich, where two umbilical cords ran separately to the placenta. According to Duncan, a similar instance is spoken of by Littré. The pubic bones are separated at the symphysis to the extent of a few inches, or the bodies of the pubes are absent, the rami being connected usually by a band or bands of firm connective tissue.—See Fig. 2. A fact relative to this point is that in birds which have a cloaca the symphysis is absent.

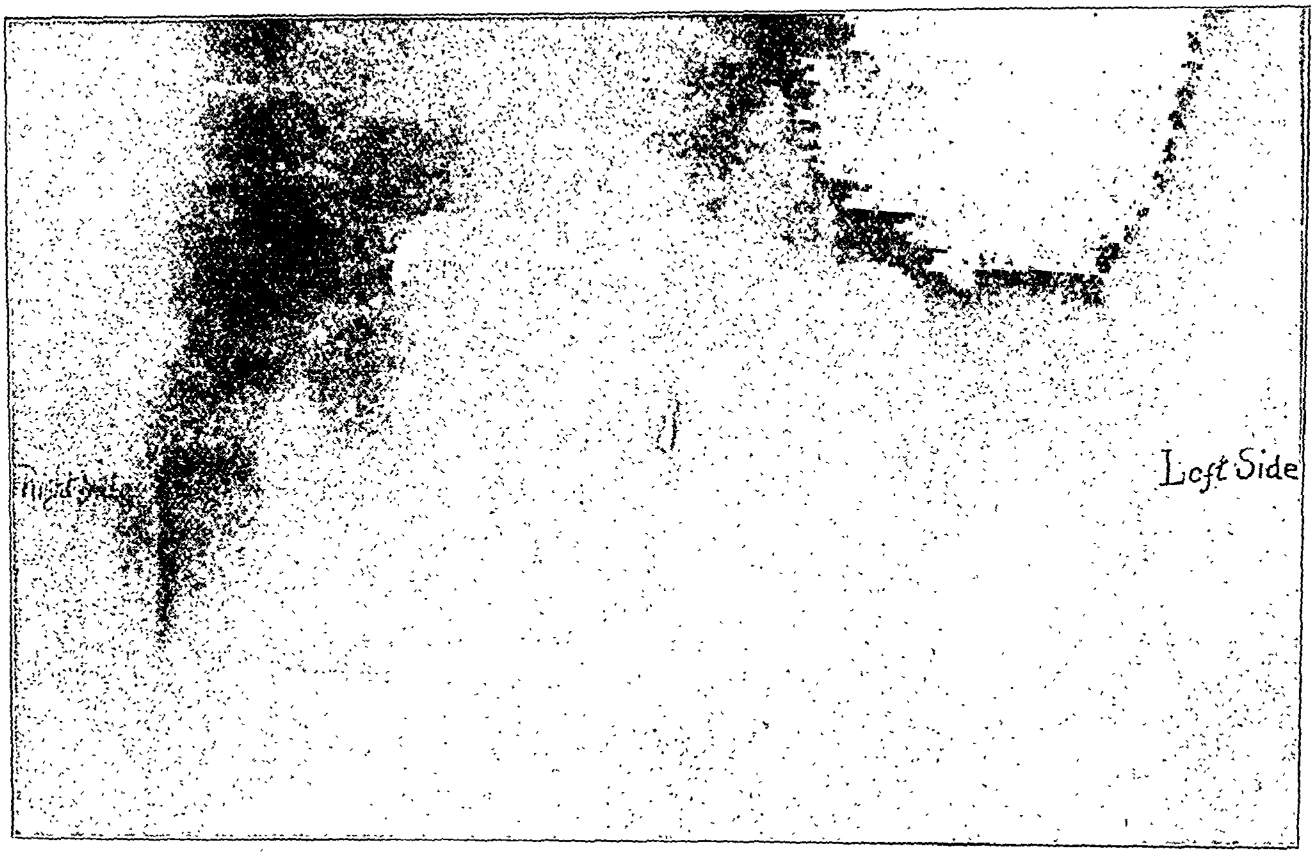
Divarication of the pubic bones, or cleft symphysis, is commonly said to be an invariable sign in exstrophy of the bladder; but cases are on record where the symphysis was perfect, as noted by Coates, Draman, Roose, Walther and Quatrefages. Exstrophy may exist without cleft symphysis; so cleft symphysis may exist without exstrophy, as stated by McWhinney, Meckel, Vrolik and Mayo. Exstrophy with cleft symphysis is the ordinary form. Exstrophy with perfect symphysis is an uncommon occurrence, as in the case of Coates and others. No exstrophy with cleft symphysis is also uncommon, as in the case of McWhinney and others, while no exstrophy with perfect symphysis is the normal condition.

This separation of the pubic bones causes a separation of the recti abdominales muscles. This is noted especially above the exstrophied mass, extending up to the ensiform, where a flat, hard and resisting surface can be felt 5 to 8 cm. (2 to 3 inches) wide at the bottom, becoming narrower as it ascends. This is the connective tissue of the enlarged and thickened linea alba; the skin over this seems perfectly normal.

The thighs are separated farther than they are normally, owing to the cleft symphysis. When coupled with a bending forward of the body trunk, in an effort to protect the sensitive mass in the pubic region, it makes the gait a very characteristic one, and if once observed will be easily recognized on another occasion. The distress of the patient is both physical and mental, physically from the constant flow of urine and from the irritation caused by rubbing of the clothing. The irritation is not confined to the tender exposed mucous lining of the bladder, but often causes intertrigo, dermatitis, and eczema of the surrounding skin, most usually of the thighs. The papillary orifices of the ureters are irritated by friction of clothes or other cause. These orifices present a warty appearance and may be seen to discharge pus or muco-pus. This appearance is aptly likened by Wood to the granular conjunctiva induced by entropion of the eyelids. This irritation and inflammation of the ureteral orifices produce the ordinary effects of obstruction, as is seen by dilatation and hypertrophy of ureter, pelvis and kidney. It is similar to the condition in ordinary pyelonephritis or surgical kidney, and in ascending infection of kidney in cases of cystitis. Mentally, he must suffer, for owing to his pitiable condition, he is excluded from society and from all the ordinary pleasures which are supposed to make life worth the living. The individual thus afflicted is usually normal in other respects and enjoys good health. This fact makes his isolation all the more pitiable. On account of the constant escape of urine, the clothing is saturated and the odor is almost unbearable to all but the patient, whose sense of smell seems to have become "acclimated," as it were. The penis is rudimentary, short and broad, and is attached to the bladder near the openings of the ureters, with an epispadius more or less complete. John Wood states that epispadius is always an accompaniment, and cites one case where only the anterior part was epispadiac, the posterior portion of the urethra being closed. Küster reports a case of exstrophy in which the penile portion of urethra was closed, and on the dorsum of the penis a white cicatrix was visible. As a rule, it can be said that epispadius does exist without exstrophy; exstrophy does not exist without epispadius. The verumontanum and the openings of the ejaculatory ducts are to be seen in the bottom of this epispadiac groove, the imperfectly formed urethra. The testicles may be descended or undescended; either in the abdominal cavity, inguinal canal or scrotum. The latter may be divided or imperfect.

Herniæ are not infrequently found in conjunction with exstrophy, either a single or double inguinal or ventral. The perineum is usually defective. The anus, being located immediately behind the scrotum, is often

PLATE II.



Skiagraph, showing Separation of the Pubic Bones in Case of Exstrophy of the Bladder. (Dr. Weiner's Case.)

imperforate, but more often perforate, with prolapsus. There is also present a general looseness of the mesentery of the large bowel and duodenum. The pouch of peritoneum, cul-de-sac of Douglas, descends deeply between the front of rectum and the posterior surface of bladder.

In the female, associated with the exstrophic tumor, the clitoris and labia may be found in a malformed or immature condition. There may be present prolapsus uteri, owing to the pelvic floor being weakened by the divarication of the symphysis. An exstrophied bladder may become carcinomatous, as in a case mentioned by Kelly. In a young male cat with exstrophy, dissected by Geoff. St. Hilaire, the conditions were found to be the same as in man.

ETIOLOGY.

The cause of the deformity termed "exstrophy of the bladder" has thus far been a matter of conjecture; and at the present time, nearly two hundred years after the detailed description of this condition by Mowatt, no theory meets with universal approval. In 1877, Francis Champneys, in reporting a case, delves into the then existing literature on the subject very extensively, and devotes considerable attention to the different ideas advanced in attempting to explain the existence of such a defect. Among the causative factors may be mentioned, not on account of any scientific value, but merely as interesting facts or coincidents, the few cases of so-called "maternal impression." One woman, who was employed in eviscerating geese during her pregnancy, gave birth to a child with exstrophy of the bladder. Another woman, one of the mob during the "reign of terror" in Paris, gave birth to a child with a similar defect. In another instance, a wife fell from a tree, alighting on her coccyx, and in describing her sensation, said that she "felt as if her insides were being forced out in front." Shortly after the accident she was confined, the offspring being perfect in every detail except the presence of an exstrophied bladder. And, also, the case reported by Mowatt where the mother had been struck by a cow's horn and "the fright remained with her and did terrify her sometimes in her sleep." An allied interesting case is recorded which may be termed one of "paternal impression." Shortly before the birth of a child the father dreamed that his son came to him and showed him the bleeding stump from which his external genitals had been removed. The child on delivery was found to have an exstrophy of the bladder.

But, passing from the fanciful to more substantial reasoning, many theories are to be found. They may all be classified under the three general headings of mechanical, pathological, and arrested development.

1. Mechanical: Breschet considered as the etiological factor the bursting of the bladder due to distention or fetal movement. Duncan placed the order of sequence as follows: imperforate urethra, distention from retention, divarication of pubic bones, and rupture of bladder. Foerster places the cause with the accumulation of fluid in allantois, preventing the closure of the abdominal wall over it. Creve thinks it is due to separation of the pubic bones. Roofe supposes the cause to be due to external injury, separating at the same time the bones of the pubes and bursting the bladder. Rose found the right kidney in the pelvis. Ahlfred regards as a cause the rupture of the exposed and distended allantois, the excretory duct of which has not been formed. Rolgans states that it develops at the end of the fourth month of fetal life, and that pressure of the umbilical cord against the anterior abdominal wall, as the fetus is head downward and the cord between the legs, would be a causative factor. Morgelin considered obstruction of the urethra sufficient cause, the obstruction and distention beginning before the visceral plates have fused to form the abdominal wall. He believes also that adhesions of the bladder to the yet ununited abdominal wall have more to do with failure to close than rupture of the bladder from obstruction of urethra. Chance deemed as a cause over-distention of the allantois, followed by rupture.

2. Pathological: Velpeau and Benjamin Phillips lay stress on the extreme thinness of the abdominal wall in the early stage of its development, and believe that then laceration or ulceration takes place, causing the defect. They also look on the absence of the symphysis pubis, not as a divarication, or simple absence, but as a necrosis of bone. They call attention to the cicatricial boundary. Chaussier notes failure of the abdominal wall to develop perfectly, then destruction of the anterior wall of the bladder. Wood usually found adhesions of the anterior abdominal wall to fetal membranes "due to inflammatory or degenerative processes arising from specific diseases, such as syphilis, etc." Perls asserts the cause to be the presence of adhesions between the lateral plates and the amnion.

3. Arrested Development: Vrolik says: "It can only be explained by an imperfect development of the urinary bladder from the allantois. It is not improbable that the urinary bladder is formed by two half parts, which approach each other anteriorly and posteriorly on the mesial line. If this juncture does not occur, the different forms of vesica inversa will occur." Meckel says that the bladder is originally a flat surface, the edges subsequently uniting. Failure of this union of edges is given as a cause. Fyres gives as a cause deficient development of the urachus—allantois. Bartels, in his case, found an abnormal opening of intestine separating the two halves of a double exstrophied bladder. He believes the allantois to be developed in two halves, and in this case, the cause was said to be due to an abnormal development of the intestine occurring before the two halves of allantois had united. Geoffrey St. Hilaire and Vrolik, because of the following coexisting malformations, considered the defect to be due to arrested development: fissures of head and face, umbilical hernia, abnormalities of intestine, imperforate

anus, spina bifida, bilobed appearance of the bladder in some instances, other defects in genito-urinary organs, occasional absence of the umbilical artery, fissured dorsal vertebræ, confluent toes, talipes, and genu valgum or varum. Reichel ascribed as a cause arrested development occurring in first weeks of fetal life, as a result of disturbances in formation of primitive streak, that is, coalescence of the borders of the primitive groove does not take place, or is defective.

This large number of various explanations is in itself sufficient to show that the causative factor or factors have not yet been pointed out. Many of these theories are at once seen to be based on a limited or imperfect observation of the cases or the literature. To the explanations classed under the heading of mechanical, the following objections have been raised: The bladder would be stronger than the abdominal wall. If the bladder ruptures, why should it always do so in the anterior wall and in a superior and inferior direction, while in adult life, when it occurs, as a rarity due to direct force or over-distention, in the majority of cases it extends from the insertion of the urachus down in the posterior wall, and the abdominal wall is never ruptured? The rupture need not be large, as a small opening relieves the pressure at once. Imperforation of the urethra does not occur; the urethra is too patent. Divarication of the pubic bones is not always present. No information is given as to how this injury to fetus causes this deformity. Pressure sufficient to cause atrophy of tissue in the abdominal wall would also be sufficient to stop or interfere with the circulation in the cord. If this pressure is the cause, why is the exstrophy so often associated with other deformities? Why is the defect so large as compared with the diameter of the cord and the area that it would press on? No case was found on record where the cord had exerted this pressure, and even partially produced this condition.

The objections to a pathological factor in etiology may be given as follows: This cicatricial appearance is seen in other deformities, such as hare-lip, and does not of necessity mean previous pathological change unless it should also apply to other deformities. If it is due to ulceration, why does not, occasionally at least, the intestine intervene between the bladder and abdominal wall and so fill in the gap or take part in the line of union? As a rule nothing except the deformity points to inflammatory change. That the os pubis is destroyed is very doubtful, and is not confirmed by any other investigator. Adhesions are not usual, and according to the majority of writers, syphilitic children are not prone to this deformity.

Under the caption of arrested development Meckel's embryology is not consistent with the facts. As to the others, under this heading, very little can be said, because no reason is presented for the sudden arrest of Nature's handiwork. It is found that the only theories which can be considered seriously are those which come under the heading of arrested development. Those falling under either the mechanical or pathological, or even combinations of these, have been shown to have some serious objection. Unfortunately, after having arrived at the conclusion that arrested development is the cause of exstrophy of the bladder, no more is known than before. And, for this conclusion to be of any practical value, the reason for Nature's stopping before her work was completed must also be known.

The causative factor in the formation of exstrophy of the bladder may or may not be of any practical importance after it is discovered and made evident to the profession. Even if the etiology is known, it may not be possible to follow that rule which has become axiomatic and universally in force in the practice of medicine and surgery, namely, "ascertain the cause and then remove it." But, knowing the manner in which the malformation is formed, the surgeon in all probability will be better able to operate in an effort to repair the defect, as is done in hernia; in the latter the philosophy of the process is known, yet it is impossible to prevent its occurrence.

ANATOMY AND HISTOLOGY.

The bladder varies in shape, size and position according to the degree of distension. When contracted it is of triangular form, its cavity assuming a Y or T shape, and is almost hidden in the pelvic cavity. When moderately full it becomes rounded, and if completely distended it is of an ovoid shape, with the larger end below and posterior, and the smaller end above and anteriorly. A line through its long axis would start from a point between the umbilicus and symphysis (depending on the degree of distension), going in a direction downward and backward, and would strike the tip of the coccyx. The average capacity of the bladder is one pint, though, of course, under pathological conditions too numerous to mention, this capacity may vary from eight or ten pints to that of a few ounces. The normal capacity, according to Hunner and Lyon in a recent and excellent work on mensuration and capacity of bladder, is 430 c.c.

The relations of the normally-formed bladder are of importance from a surgical standpoint. Anteriorly, the bladder is in relation with the triangular ligament of the urethra, subpubic ligament, symphysis and body of pubis and, if distended, with the lower part of the anterior wall of abdomen. The wall of the bladder is separated from these structures by loose areolar tissue and connected to the pubic bones by means of bands of fascia, designated in this location as the anterior true ligaments—pubo-prostatic, or pubo-cystic ligaments. Posteriorly it is in relation, in the male, with the rectum; in the female, with uterus and vagina; in both, loops of small intestine may intervene. Superiorly it is in relation with the abdominal or peritoneal cavity, the urachus, and loops of small intestine. Inferiorly it lies over the urethra and prostate. Laterally, the sides, when distended, are rounded and prominent. When empty, they are merely curved edges. At the upper part it is in relation with the peritoneal cavity and loops of small intestine; in males with the vas deferens; in females, the viscus is connected with the fascia by means of loose areolar tissue, which is continuous with the broad ligaments. Each side is crossed obliquely by the obliterated hypogastric artery, which joins the superior vesical artery and also serves for attachment.

The bladder, though a movable, or rather a distensible, organ, is held quite firmly in position by means of true and false ligaments. The true ligaments, so called because formed of folds of rectovesical fascia, are five in number: two anterior ligaments, extending from pubes; two lateral ligaments, extending from lateral wall of pelvis, and one, the urachus, serving also as a ligament. The false ligaments, formed by folds of peritoneum, are also five in number: two posterior, from sides of rectum or uterus, form the lateral boundary of reco-vesical fold of the peritoneum, and contain the ureters and obliterated hypogastric arteries. The two lateral are reflected folds of peritoneum from the iliac fossa; and one superior, a fold of peritoneum extending from the fundus to the umbilicus, covering the urachus and obliterated hypogastric artery.

The base of the bladder is a very important part of the organ. In the male it is triangle-shaped, bounded at the sides by lateral surfaces; in the front by the base of the prostate, and behind by the cul-de-sac formed by the rectovesical fold of the peritoneum. Behind the prostate are the vesiculæ seminales and vasa deferentia. The base of bladder is directed backward as well as downward and rests on the second portion of the rectum, to which it is adherent by dense fibro-areolar tissue. The bladder may be punctured through the rectum at this point without injuring the peritoneum. But in exstrophy the peritoneum dips down much deeper, as was found in Lloyd's case. In the female, it is separated from the rectum by the vagina and cervix. This part of the organ adheres to the vagina, its relationship depending on its degree of distension. The "neck of the bladder" is a phrase used to designate the junction of bladder and urethra, and by some anatomists to include the prostatic portion of the urethra. It is the lowest portion of the bladder when the individual is standing erect.

Blood-supply.—The arteries are the superior vesical and the obliterated hypogastric; the inferior vesical, which usually arises from the superior vesical; the middle vesical; the obturator, which gives off a visceral branch; and the sciatic, which occasionally does the same. All of these arteries arise from the anterior trunk of the internal iliac. The veins do not accompany the arteries constantly. They form an irregular and inconsistent network of vessels, which surround the lower part of the viscus more abundantly than its fundus—the vesicoprostatic plexus. These veins all terminate in the internal iliac vein.

Lymphatics.—These vessels arise from the entire surface of the organ, chiefly on the posterior surface and neck, and run beneath the peritoneal coat through small glands to join others from the prostate; they finally enter the internal iliac glands.

Nerve-supply.—The bladder is in communication with the central and sympathetic nervous system by means of the sacral plexus of the former and the hypogastric plexus of the latter. The nerves arising in the hypogastric plexus have been traced almost exclusively to the fundus of the bladder; those originating in the sacral plexus, and especially the branches of the fourth sacral nerve, are distributed to the neck and base. Some of these nerves are distributed to the muscular coat and others to the mucous membrane. Microscopic ganglia are found along the course of the nerves in the bladder.

The wall of the bladder is composed of the following layers from without inward: 1, serous; 2, longitudinal muscular; 3, circular muscular; 4, submucosa, and 5, mucosa.

1. The serosa or peritoneal is not complete. The anterior surface is almost entirely devoid of peritoneum when the bladder is empty. The peritoneum is reflected from the bladder to the anterior surface of the abdominal wall, where it changes from visceral to parietal peritoneum. When the bladder is distended the urachus is not sufficient to prevent the falling down of the peritoneum as a cul-de-sac, and covering a large part of the superior portion of its anterior wall. This space, anterior to the wall and below the peritoneum, was first described by Retzius, and hence is called cavum Retzii, and is of great importance in cystotomy by means of the suprapubic incision. Laterally, the serous coat does not invest the entire surface, being absent below the obliterated hypogastric arteries. The posterior surface is entirely covered by the peritoneum. The base is only partly covered by this outer coat; it is absent where the bladder and rectum (or vagina) are in intimate relationship. The structure of this membrane is necessarily the same as the serous membranes in other parts of the body. It is composed of a layer of endothelial cells resting on a layer of connective tissue.

2. The longitudinal coat is composed of unstriped muscular fasciculi. It is separated into more or less perfect subdivisions of outer, middle and inner layers. The outer longitudinal layer originates from the body of the pubes—musculo-pubo-vesiculis—and extends up the anterior surface, over the summit and down posterior surface, becoming attached to the prostate, or in front of the vagina in the female. The fibers are somewhat oblique on the sides, and of course overlap each other. This layer has been named the "detrusor urinæ." Mercier ascribed to this muscle a double function: *a*, to force the urine toward the neck of the bladder, and *b*, to open the orifice and keep it so during the act of micturition.

3. The circular muscular or the middle layer is not particularly noticeable over the body of the bladder, but at the neck the fibers unite, forming the circular band of muscle called the sphincter vesicæ. The mus-

cular fibers of the neck have been described as descending into the urethra, or into the verumontanum or capus gallinaginis of the urethra. It is supposed that this structure acts as a valve to the urethra, falling down into the tube and obstructing it when the sphincter is closed and rising up so as to stand erect in the middle line, thus allowing the urine to flow by during the act of micturition. The internal longitudinal layer is thin and inconspicuous, except where two oblique bands of fibers originate behind the orifices of the ureters and converging become united and are inserted into the prostate gland or vagina. These were called "muscles of the ureters" by Sir C. Bell, and are supposed to maintain the obliquity of the ureteral insertion while the bladder is contracted, thus preventing regurgitation.

4. The submucosa is not very marked and consists of an interlacing of very loosely connected areolar tissue connecting the muscularis and mucosa in such a manner that the latter may be able to move considerably over the former. Within this layer are found the vessels and nerves which supply the mucosa.

5. The mucous membrane of the bladder is continuous with that lining the ureter and urethra. It is composed of epithelium in layers of cells, each stratum being composed of cells differing in size and shape from those of the other layers. In the deeper layer, that which rests on the submucosa, the cells are roughly columnar in shape; in the middle layers, more round or ovoid, and in the superficial layers the individual cells are distinctly squamous in configuration, the so-called "transitional or stratified squamous epithelium." The mucosa is connected to the muscularis loosely by the submucosa, and hence is capable of a limited independent motion. If the viscus is empty the mucosa is usually thrown into folds, which are not permanent, as they disappear on distending the bladder. At one situation, the triangular area at the base, these folds or rugæ do not appear, owing to a more firm attachment to the muscularis. The mucous membrane shows no villi. Small racemose glands are to be found, especially at or near the orifice of the urethral opening. Small lymph-follicles are also present in the mucosa of the bladder.

The inner surface of the bladder presents at its base the trigone, trigonum vesicæ, or "triangle Lieutaudii." This is, as the name implies, a three-sided space, with its apex located behind the urethral orifice, and its base bounded on each side by the openings of the ureters. This space is almost an equilateral triangle measuring about 1½ inches (3 to 4 cm.) on each side. The mucous membrane over this area is bound quite firmly to the muscularis and presents no rugæ. Immediately behind the posterior border of the trigonum the base of the bladder is normally more or less sunken, and is termed by the French the "bas fond." In cases of hypertrophy of the prostate or muscular atrophy or weakness this is the region which becomes deeper and is the seat of retention with its chain of symptoms and often of calculiformation. In many cases an increased thickening of the submucosa, causing an elevated ridge of mucous membrane extending from the trigonum forward to the urethral orifice, is present, which has been called the uvula vesicæ. This divides the bladder into two halves, which may have something to do with embryologic formation.

The openings of the ureters into the bladder are quite peculiar and of the greatest surgical importance. The ureters are inserted into the bladder obliquely, according to Cabot, extending obliquely for the distance of 1 to 1.5 cm. between the mucosa and the muscularis. The opening on the mucosa is one at each superior angle of the vesical trigone. The orifice is at times difficult to locate, owing to lack of any visible opening and little or no change in the surrounding mucosa. At other times the opening is at the tip of a prominence, the "mons ureteris" of Kelly, or it may be in a more or less distinct depression. Kelly found in young nulliparous women, at the ureteral opening, a small round dark point, which was never observed in multipara. This oblique insertion is supposed to act as a valve in preventing regurgitation. The peculiar muscular bands described as running from the ureteral orifices to the prostate were supposed to be for the purpose of maintaining this oblique insertion even with marked contraction of bladder. The first to point out this valve-like action of the ureteral insertion was J. L. Petit, a Frenchman, who early in 1700 called attention to the fact that when the viscus was dilated the anterior wall of the duct was brought forcibly into contact, and held so, with the posterior wall of tube, thus sealing effectually the opening and preventing any back-flow. The fact of dilatation of ureters and pelvis of the kidneys was rationally explained by stating that the inferior orifice was closed; hence, urine could not escape as it was secreted from the kidney, and as the gland continued to functionate necessary dilatation of duct and pelvis occurred. This was accepted as an established fact for many years. With increase in knowledge and more accurate methods of observation it soon became a well-recognized fact that inflammation of the ureter and kidney did take place as a result of cystitis. These facts led to experimentation on the lower animals. Lewin and Goldschmidt, in 1893, reported experiments made on dogs and rabbits. Colored fluid was injected into the normal bladder, and the colored particles afterward found in the ureters and pelves of the kidneys, in all probability carried there by an antiperistaltic movement. Courtade and Guyon repeated the above experiments with the same results, but noted the fact that the regurgitation occurred with less frequency in dogs, where the muscular development was more marked. Kelly, in recording his own observations on the reflux of air into the ureters, has noticed this phenomenon in at least twelve cases. The air enters without being perceived, but it soon becomes heated and then escapes in visible bubbles at the ureteral orifice.

He says in conclusion: "The fact that gas will enter the ureters simply shows that they are not air-tight under some conditions, and does not prove in any way that they are not water-tight under physiological conditions." These experiments, accompanied by observations, have caused it to be an acknowledged fact that regurgitation may and does occur, but not under normal conditions. When it does occur there is some pathological activity in the vicinity; or the fact that regurgitation does take place, if not followed by pathological change, will not be noticed. The experiments above cited demonstrate conclusively that regurgitation may and does occur in the normal bladder of the lower animals. Under normal conditions, if the valve becomes defective and nothing but plain non-infected urine regurgitates, no more damage is done than when the urine secreted by the kidney can not escape and there is resulting dilatation of the ureter.

But if septic matter, infectious material, is in the bladder, then the necessity under this abnormal pathological condition for a perfectly working valve is imperative. The experiments with clinical experience show conclusively that this valve is sometimes defective. The importance of the ureteral valve can not be overestimated, and certainly should be considered carefully before attempting implantation of this valve into a septic cavity like the rectum, sigmoid or colon. Another valve, like unto this, is sometimes defective, namely, the opening of the ductus communis choledochus, the mechanism of which is quite similar. It has been clinically established that this orifice is many times at fault, as in catarrhal cholangitis.

The ureter claims our attention when considering exstrophy of the bladder. It is a muscular tube 25 to 30 cm. (10 to 12 inches) in length, extending from the kidney to the bladder. On account of the higher position of the left kidney, the left ureter is longer than the right. The diameter is about that of an ordinary goose quill, 3mm.; but this is only an average diameter, and is not uniform, the tube presenting three quite constant points at which a diminution in the caliber will be found: 1, at a point 3.5 to 5 cm. (1½ to 2 inches) from pelvis of kidney; 2, the place where it crosses the iliac artery, and 3, at the junction of its pelvic and visceral portion. The duct runs a sigmoid course, its length exceeding the shortest distance between kidney and bladder. At the pelvis, on a level with the spinous process of first lumbar vertebra, the ureters are 9 cm. (3½ inches) apart; at the ileopectineal line, 6 cm. (2½ inches); at ischial spines, 10 cm. (4 inches); at entrance into bladder, 4 cm. (1½ inches). On account of this tortuosity the ureter may be picked up and lifted 3 to 4 inches into the abdominal incision without doing any serious damage. Also in implanting it into neighboring tissues or organs, its lower end will permit of considerable transportation owing to this S-shaped course. The function of the ureter is to carry the urine from the kidney to the bladder, and in doing this the muscular coat is called into action, as is seen in the peristaltic movement descending in waves at regular intervals. Thus, the function is not passive, but active. This peristaltic action was noticed by T. Smith, in 1879, while transplanting the ureter into the colon, and he spoke of it as follows: "It was observed that more urine flowed from the right ureter than from the left, and that the flow was not continuous, but at intervals; the ureters contracted and forced the urine out with a gush, etc." Kelly tells of starting this action by manipulating or pinching a ureter during an operation. The ureter is in its entire course extra- or retro-peritoneal, located in the retro-peritoneal space and surrounded by a layer of loose fatty tissue. It imparts a peculiar sensation when grasped by the fingers, and may be seen as a white cord behind the peritoneum, to which it is attached. This attachment was suspected, but it is due to Cabot's work that the fact was demonstrated under the microscope. Thus, in stripping the peritoneum, the ureter is always removed with it. When searching for the ureter in its upper portion, Cabot noted that the ureter was just external to the line of adhesion of peritoneum to the spine. In searching for the ureter in the pelvis, it can easily be located at the pelvic brim at the division of the common iliac artery. For convenience of description, the ureter has been arbitrarily divided into abdominal and pelvic portions, the dividing line being at the common iliac artery, about 3 cm. above the brim of the pelvis. The abdominal portion is about 12 to 15 cm. (5 to 6 inches) long. In passing down from the large into the small pelvis, the left ureter lies between the vertebræ and psoas muscle; the right ureter, on occount of the inferior vena cava, is situated a little more laterally.

The pelvic portion has, as a whole, a sigmoid course, and is from 10 to 12 cm. (4 to 5 inches) long. It is at first on the inner side of the internal iliac artery. In the upper pelvis it presents, acording to Glautenay, the following relations: It crosses the iliac vessels, lying behind the ileum on the right side and the sigmoid on the left side. It crosses over the pyramidalis and the obturator internus, separated by pelvic fascia; at this location it is behind the obturator and umbilical arteries, branches of the hypogastric. In the remainder of its course in women, it is crossed by the ovarian artery and vein, and the uterine artery. It passes through the base of the broad ligament, through a sort of ligamentous foramen, half way between the pelvic wall and cervix, along upper lateral vaginal wall; then curves to the anterior vaginal wall, terminating in the bladder midway between the cervix and meatus urinarius. In man it is crossed by the vas deferens and differential artery; then it passes on to the anterior surface of the seminal vesicle and enters the bladder, above the prostate.

The blood-supply consists of renal, spermatic, internal iliac and inferior vesical arteries. The blood-supply of the ureter is a question of vital importance when implanting it into neighboring structures or organs. Any such procedure will necessitate the freeing of the duct for some distance, and hence the danger of separating it too much and interfering with its nutrition. Margarucci found a branch of the renal artery accompanying the ureter almost to the bladder, in dogs. From these, branches penetrate the walls to supply the mucosa. The ureter receives its blood-supply, for but a short distance, from the vessels of the bladder—hypogastric. It has its own vascular system, a branch of the renal, and does not anastomose to any extent with surrounding vessels. This would account for the possibility of isolating it from its surroundings without causing necrosis. Monari calls attention to the branches of the spermatic artery which serve to supplement those of the renal artery. These two branches form the main arterial system of the ureter, that coming from below the bladder being so small as to be hardly worth mentioning. Monari also studied on dogs the extent to which the ureter could be isolated from its surrounding connective tissue without causing necrosis. He found that from 12 to 13 cm. (5 inches) did no harm, if it was carefully replaced in contact with the tissue from which it was removed and the peritoneum allowed to cover it again. On the other hand, if isolated and kept away from adjacent tissue, as by wrapping gauze around it, if only to an extent of 6 cm., necrosis and leakage would result. The nerves are derived from the inferior mesenteric, spermatic, and hypogastric plexuses. The veins are not constant in their course and end in various neighboring vessels. The lymphatics are well developed, and form several networks between the different layers of the ureter. The wall of the ureter is 1 mm. thick and consists of three layers: fibrous, muscular and mucous. The fibrous layer is continuous above with the capsule of the kidney, and below with the fibrous capsule of the bladder. The peritoneum is connected by fibrous bands from this coat to the anterior wall throughout its whole extent. The muscular layer has been variously described as being subdivided into an outer and inner longitudinal, and a middle circular; and, again, as consisting of only an outer circular, and an inner longitudinal. There is no sphincter-like arrangement at the vesical orifice. The mucous membrane is continuous with that of the pelvis of kidney above, and of the bladder below. It may present longitudinal folds which are not permanent, as they disappear on dilatation. The mucous membrane is the transitional epithelium. No glands or papillæ are found.

HISTORY.

The literature of exstrophy of bladder is of comparatively recent date. According to Mazel, nothing relative to the condition is to be found in the writings of Hippocrates or Galen. The records of the "middle ages" are similarly devoid of reference to this subject. The first case reported appears as late as 1595 and is presented by John Schenke. A similar case was also recorded about the same time by Tobias Cneulin. It is not until 1670 that the first record of a female case is found, which is reported by Van Horne. Thus it is found that the sixteenth and seventeenth centuries pass with their pages practically blank in relation to this condition. But during the eighteenth century, the attention of medical men is being attracted to it, and in 1713, a peculiar case is recorded by Richardson, as follows: "One John Warnsnope, of North Brierly, a poor boy, lived until he was 17 years of age and never made water, and yet he was very healthy, vigorous and active. He constantly had diarrhea on him, but without much uneasiness. The obstruction must have been in the kidneys, for he never had any inclination to make water. The serous part of the blood, which should have been thrown off by the urine, was discharged by the celiac and mesenteric arteries by the mediation of the glands into the guts. He died from fever." The above was written 187 years ago, and is interesting, because in all probability it was a case of ureterorectal, or vesicorectal anastomosis. The fact that the boy lived seventeen years is significant and of value at this time, when the Maydl method of treatment is being so widely discussed.

Huxham and Bonnett, under the title "Preternatural Structure of the Parts in a Woman, with an Account of Delivery," report the case of a woman who was 27 years old, in 1722. She was married, and had become pregnant. At the time of delivery, the physician was dumbfounded at finding neither vulva nor vagina. As a last resort, a free incision was made in the lower part of the abdomen, or where the vulva should be, and the successful delivery of a full-term child was accomplished. No mention of exstrophy of the bladder is made at this early date, but there can be no doubt that such was the condition existing.

Mowatt, in 1735, gives the following description of a case which came under his observation. This is the first valuable article to be found in the available English literature. "In November, 1732, a child was brought forth whose funis umbilicus was tied to the upper edge of a deep hole, and just above the ossa pubis this deep hole penetrated the peritoneum; but now a lump of spongy flesh rises out of it. The edges of the hole were at first and are now found sound. From the spongy flesh of this hole arise two papillæ about the size of the point of an ordinary probe, at which the urine constantly oozes; but when the child cries, the urine jets out as blood from the aperture of a small artery. The papilla on the left side is now closed, but the other keeps open as at first, through which the urine continually oozes and scalding all the parts, keeps them very raw. The penis arises immediately at the under side of the hole, was at first much less in size; it was and still is imperforated, and flat on the upper side next the glans, as if it had been slit longitudinally. It has two small veins and a large prepuce inverted. The scrotum and testes were and continue in a good condition; the scrotum is corrugated very close to the end of two prominences; the raphe appears in its middle with wrinkles on each side; the testes lie under the prominences; they can be moved from the place they are seated in, either higher or lower as we please to put them. The distance between the scrotum and anus is longer than it should be; and the ossa pubis are longer and flatter than in other children. There is a large prominence on each inguen under which the testes lie. The child is healthy, active and stirring, and is very much affected with his misfortune; for he frequently cries upon viewing himself, and is very unwilling any other should see these parts. The mother is a very healthy woman; has brought forth another child every way sound and right in all its members. She tells that in May, before she was brought to bed of this her first child, she was struck in the belly with a cow's horn; she recovered the hurt in two or three days, but the fright remained longer with her, and did terrify her sometimes in her sleep. I have twice or thrice thrust down a small silver probe at the right papilla about an inch or more, but can not feel it in the perineum. I have also closed up the papilla two hours and three-quarters with a small tent and an astringent plaster over it, but can discover no swelling in the perineum, but rather in the belly. Upon withdrawing the tent the urine squirted a great way, but by the uneasiness of the child and the anxiety of the mother, I'm obliged to desist at present from any further experiments."

Devilleneuve, in 1767, reports a case, giving a comparatively accurate description of the condition found. In 1749, Buxtorf, assuming the condition found to be a hernia, made an attempt at relief in his case by applying a "plaster bandage."

The first rational attempt at treatment appeared near the close of the century in the silver-bowl of Jurine, of Geneva. The principle of this apparatus, the first and original method of treatment, is still in use at the present day, though, of course, the archetype of Jurine can at this date be hardly recognized, owing to the many important improvements and modifications. An apparatus for use in exstrophy is still recommended. Toward the end of the century there appears an account of a man 20 years old, in 1791, a certain Mathew Ussen, who is designated as a German traveler, was in the habit of going from place to place, and it is judged that he presented himself to medical men for examination, by whom he was looked on as a very rare curiosity. This Ussen was fitted with one of these silver bowls by Bonn, of Amsterdam. Upon seeing this same case, Roofe suggested connecting the "bowl" with a reservoir by means of a hollow tube.

It will be safe to make the assertion that, at the beginning of the eighteenth century, what is to-day known as exstrophy of the bladder did not exist and was not known as such 200 years ago. That there were cases then, as now, no one will question, but that they were not recognized, nor the true significance of the defect understood, must be admitted. The coming of the nineteenth century brought with it a fairly good knowledge of what to-day is known as exstrophy of the bladder. Yet, leaving out the Jurine apparatus, very little advance had been made in attempts at treatment. Cases were recognized and reported with greater frequency, to be sure, and they had to a certain extent lost their novelty. In 1805 Duncan collected 50 cases; in 1828 Earle collected 68 cases, and in 1833 Velpeau, about 100 cases. But if the profession as a whole understood what had taken place, it was far from being a unit as to the cause. It is to be observed, as significant of the trend of thought at this time, that when a case was reported, it was not deemed sufficient to record the facts as found, but at the same time to theorize as to the cause of this unfortunate side-step on the part of nature. To think of "granting nature the exercise of reason in her operations," shows that man must have been keeping a somewhat close watch on Dame Nature and her methods. As showing the interest which had developed at the time, there appear in the *Edinburgh Medical and Surgical Journal* for 1805, three articles on this subject. One was by W. H. Coates, presenting the case of a female with the peculiarity that the symphysis was perfect. Another case was in a female, reported by Sir Astley Cooper, where the ureters were increased in size to that of the rectum, and a masterly review of the existing literature on the subject by Andrew Duncan, Jr.

Dubois and Dupuytren suggested, in 1806, that it might be advisable in these cases to attempt to bring the defective pubic bones in apposition at the median line by the application of a compression bandage. Soden, in 1808, reports a case which was peculiar, in the difficulty with which the sex of the child was determined upon.

In 1827 Hamilton presents the first case which appears in the literature from an American. This case was of unusual interest, because of the patient being delivered of a child at the age of 40, and subsequently lived to the age of 80 years. In 1832 is found an admirable description of this condition by J. J. Schneider, and also an exhaustive thesis on the same subject by J. L. A. De Quatrefages.

During the remainder of the first half of the nineteenth century, there are found among many reports of cases, a few suggestions as to treatment, all of which were tried and usually found wanting. One was the method of Earle, where cauterization of the exposed mucous membrane was resorted to. Mowatt and others made the attempt to dilate the ureters in the hope that they could be made to take the place of the defective bladder. Wattman, Gerdy and Langenbeck's cases are noted, in which attempts were made to close the cleft by sutures.

The suggestion by Delpech, Bünger and Froriep that flaps of skin from adjacent surfaces might be utilized were all recorded before 1850. At that time McWhinney presented a very exhaustive paper on the subject, covering thoroughly the literature up to that date.

During the sixth decade, remarkable progress was made. Chance, in 1852, as an introduction to a presentation of two cases, says: "To the surgeons such cases are interesting because hitherto, as far as I know, they have entirely baffled every attempt at treatment. To the physiologist, however, they are still more so, because the agreement between them is so great that it proves such malformations are not the mere result of accidental erroneous development, but arise from some specific error acting invariably in the same manner, the nature of which error has not as yet been exactly determined." Following this, are the suggestion of Roux, that the ureters be transplanted to the rectum, and the operation of Mr. Simon, namely, ureterorectal anastomosis; that of Mr. Lloyd and Mr. Athol Johnson, vesicorectal anastomosis. Then came the first typical flap operation, that by Roux, who was succeeded by others; the decade ended with the comparatively successful cases of Drs. Pancoast and Ayres.

Despite this increase in the literature, that the condition of exstrophy of the bladder was still quite a rarity is shown by the report of Porter, in 1855, in an article entitled, "Bladder Outside of the Belly," where he gives a very accurate and complete description of a case, in part as follows: "A monstrosity so rare that comparatively few physicians of this country have ever had an opportunity of seeing it. Dr. Gross, of Louisville"—later of Philadelphia—"has seen but one, and that the individual in question. Professor Eve has seen two others, one of them in Great Britain. About 70 cases have been recorded in Europe, and a dozen in the United States. *And, alas! there is no remedy for this dreadful deformity.*"

From 1860 till 1870 the flap operation was employed almost exclusively; and it was during this period of time that the method approximately reached perfection. Holmes presented a number of successful cases, on one of which he performed a vesicorectal anastomosis, on the principle of Lloyd, but by a different method. Wood introduced his method, which was destined to become the preferred flap operation. He operated on many cases, with remarkably few failures. In 1867, Thiersch presented to the profession a variation in the flap procedure, that is, the use of granulating flaps. During the next decade, in the vast majority of cases operated on, flaps were utilized. In this period, the method presented by Wood was repeated and underwent many modifications. The same can be said of the Thiersch method, but to a less extent. In 1872, Rose attempted to control the incontinence by making a communication between the vagina and rectum, and then diverting the urine into the rectum by closing the vagina. In 1876, Levis presented his ingenious procedure, and in 1879, Thomas Smith repeated the principle of Mr. Simon's operation. In 1881, Thiersch repeated the procedure of Holmes, in making a vesicorectal anastomosis. Glück and Zeller reported the result of their experimental work on dogs, and Sonnenburg presented his method. In 1885, another variation is advanced by Trendelenburg in his method, which might be called the osteoplastic. The remainder of the decade was occupied in repeating or slightly modifying the methods already presented. At the close of this decade, in 1889, Segond reported a new feature, being in reality a modification of Sonnenburg's, but still characteristic enough to be differentiated by his name.

At the beginning of the tenth decade, a great deal of work was being done experimentally in the implantation of the ureters into the rectum, on the lower animals. A few such procedures had been undertaken on the human being, but with an unfavorable outcome, by Küster, in 1891, and Chaput, in 1892. R. H. Reed, in 1892, did some very interesting experimental work; and, in 1893, Van Hook, in his notable work on the ureter, devoted some time to ureteral implantation. In 1894, Maydl presented his method of ureteral implantation, which has met with almost universal success. Boari, in 1896, brought before the profession a device, resembling in some respects the Murphy button. This was followed by Chalot's aparatus, in 1897.

After the introduction of Maydl's method the authorities seem to have become divided. One class believed in the efficiency of the "valve"—the normal ureteral opening—to prevent ascending infection; while others considered this, as a safeguard, practically worthless. Those lacking confidence in the trigone as a barrier against ascending infection worked with the object in view of devising some method by means of which infection would be effectually prevented from involving the ureter and kidney; and those who were satisfied with Maydl's operation for exstrophy, carried on the same work with the complete removal of the bladder—as in tuberculosis and neoplasm—as the end in view. In 1896, Krynski and Vigoni published, each a work along this line. Pousson reported also some interesting cases, and has tabulated 52 operations, by various methods, since 1889. These were followed in the next year by Pisani, who, in so far as he preserves the trigone, has merely modified the principle of Madyl. Mathes reviews the subject of ureteral implantation into the intestine, and reports two cases operated on by Eiselberg, after the Maydl method.

Toward the close of the century, and especially during the last few years, the literature has increased at a wonderful rate. During 1898 and 1899, Fowler and Martin each present a work on this interesting phase of the subject. The years 1899 and 1900, are found to be very prolific of contributions on this no longer neglected subject. Maydl reviews the operations by his method. The cases of Allen, Josserand, and Herczel add to the list, without increasing the mortality rate. Among other recent additions to the literature are: The masterly review of the subject by Mazel;

the brief, concise, thorough and very interesting discussion by R. Matas; the extremely interesting plastic operations of Rutkowsky and Mundell; the revival of the vesicorectal anastomosis in a much more practical method by J. Frank; the successful bilateral axial implantation for tuberculosis by C. Beck, of Chicago, and another for sarcoma by Krause; the unilateral case by Lenden, and the experimental work of Kalabin; the utilization of Sonnenberg's method by J. Rilus Eastman; the employment of the skin-flaps by Wheaton, Means, De Forest Willard, Shimonek and others; and the very recent experimental work reported by Peterson.

TREATMENT.

In considering the treatment for exstrophy of the bladder, the different methods may be classified under palliative and radical. The former includes all methods which, when completed, do not give to the individual control over the evacuation of urine; the latter includes all methods wherein the result does admit of the patient retaining the urine for a variable length of time. The object of the palliative method is, primarily, the covering and protecting of the tender mass of tissue; secondarily, the formation of a cavity variable in capacity, with usually no sphincter-action at its orifice, or if present, very weak and inefficient; and thirdly, the placing of the structures in such a manner that the out-flowing urine may be more easily conveyed into a suitable receptacle. By the radical measures the object in view is to utilize the sphincter ani as a sphincter, and the rectum, or some portion of the intestinal canal, as a receptacle. The sphincter vesicæ is beyond recall, and in consequence the sphincter nearest at hand is called into service. Many attempts at repairing of the sphincter vesicæ have been undertaken, but with almost uniform failure. But the method of treating epispadias, suggested by Trendelenburg, if carried out in conjunction with the flap operation, may some time produce quite an efficient sphincter. Trendelenburg cites a case which, after operation, could retain the urine for three hours. The fact, that in suprapubic cystotomy the opening may and does assume the properties of a sphincter, has been cited, but it must be remembered that this sphincteric action is due to the part played by the recti abdominalis muscles, which are in apposition, and the suprapubic opening between them. In exstrophy the recti muscles are separated from each other for a distance of from 1 to 3 inches, and, therefore, can not exert any sphincteric action.

A—Palliative.

I.—Apparatus.

II.—Flap. 1. Of skin: *a,* epidermis in (reversed); *b,* epidermis out. 2. Of mucous membrane: *a,* remaining bladder wall of patient; *b,* intestinal wall of patient; *c,* bladder wall of lower animals.

III.—Suture of edges of fissure: 1. By direct suture. 2. Preceded by preliminary measures.

IV.—Miscellaneous: 1. Dilatation of ureters. 2. plaster bandage. 3. Catheters in ureters. 4. Fistula in perineum. 5. Ureters inserted into the urethra. 6. Nephrectomy on one side and lumbar ureteral fistula on the other.

B—Radical.

I.—Axial implantation. 1. By sutures. 2. By apparatus.

II.—Vesicorectal anastomosis.

III.—Implantation of trigonum vesicæ.

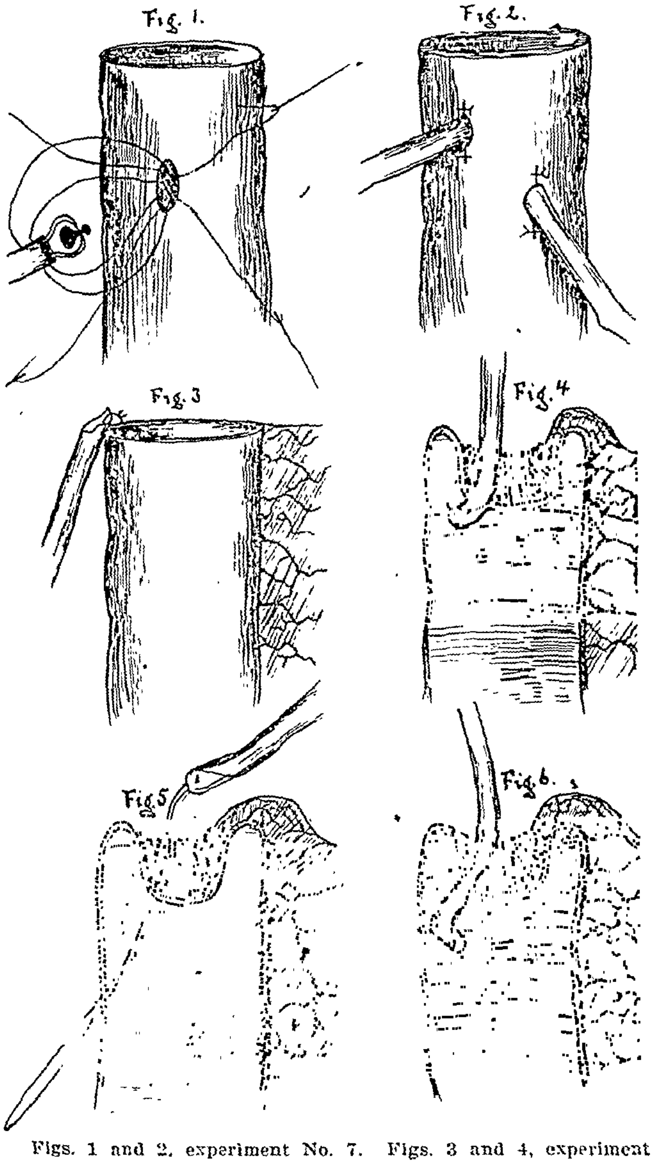
IV.—Implantation in a manner imitating normal insertion into the bladder; or an attempt to make a valve.

V.—Miscellaneous. 1. Vesico-vagino-rectal fistula, with colpocleisis. 2. Artificial anus; ureters inserted into rectum. 3. Artificial bladder: *a,* opening into urethra; *b,* opening into intestinal tract.

Palliative.—A. I. Apparatus. The efforts in this direction consisted in the application of an apparatus to cover the exposed mucous membrane. Jurine, of Geneva, was the first to contrive an apparatus meeting the requirements, which became known as the "Jurine bowl." This receptacle was attached to the anterior wall of the abdomen, immediately over the exstroverted bladder, and held in place by means of a belt and buckles. Being detachable, it was removed at night, cleaned and replaced each day. When properly applied, this contrivance controlled to a great extent the offensive odor. Likewise, it protected the delicate mucous membrane of the bladder, prevented excoriation of the adjacent integument by intercepting the escaping urine, and altogether was a priceless boon to the healthy, active young person thus afflicted. Bonn, of Amsterdam, in 1781, was the first to recognize the advantages of this apparatus. He modified the same and, as well as others, used it quite extensively, thus really introducing and establishing its merits. See Plate v, Fig. 1. This form of treatment was further improved by Roofe, in connecting the bowl with a reservoir by means of a tube. Another step in the treatment was the recommendation of Earle, that by cauterization of the mucous membrane, new connective tissue would form, which in contracting would reduce in size the space to be covered and at the same time lessen the sensitiveness of the area on which the bowl or shield would rest. This method of treatment in exstrophy of the bladder, though the oldest, is still recommended at the present day by many authorities. See Plate v, Fig. 2. "An instrument for everted exstrophy of bladder consists of a metallic or hard-rubber shield, to the lower extremity of which is attached an elastic tube, leading to a soft-rubber pouch, to collect the urine. This is buckled to the thigh, or may be carried down to the boot."

A. II. Flap, 1*a.*—Roux was the first, in 1852, to perform the regular flap operation, that is, the dissecting up of a portion of skin, leaving it attached at one point, its base, and turning it over as a leaf in a book on the exstrophied mass, with the epidermis in. He used an abdominal and a scrotal flap, which were sutured over the mass. The stitches yielded and the flaps sloughed. Richard, in 1853, resorted to a modification of Nélaton's method of treating epispadias. He brought down an umbilical flap reversed. Then he dissected a scrotal bridge-flap, which was placed on the umbilical flap. This was the first application of superimposed flaps. The reversed flap with wound surface out was covered by the bridge-flap with raw surface in, thus giving normal epidermis on the outside, and the two wound surfaces in contact. Alquié, in 1856, used superimposed flaps, but added the new feature of effecting this in two steps. He was the first to make the flap operation in more than one sitting. Pancoast, of Philadelphia, in 1858, made the first successful flap operation. He used lateral semilunar flaps and sutured them in the median line. Primary union resulted, except at the inferior angle, which point was to have been operated on at a future time. But the patient died of pneumonia two months after the first operation.

PLATE III.



Figs. 1 and 2, experiment No. 7. Figs. 3 and 4, experiment No. 8. Figs. 5 and 6, experiment No. 10.

Ayres, of Brooklyn, in 1858, was the first to report a successful case. A single curvilinear abdominal flap was employed, resulting in primary union of all except at the lower part of the line of union. This small opening was closed at a subsequent operation. This case was peculiar, in that the patient had been delivered of a child two months previous, with a resulting prolapsus uteri, which disappeared as a consequence of the operation. Holmes, in 1862, used lateral, superimposed flaps, the superior border of the flap being sutured to the abdominal wall at a second sitting. He has reported five cases with three successful results. The flap method which has met with the most favor and has been performed with success, such as accompanies a successful flap operation, is that performed, in 1863, by John Wood, of London. See Plate v, Figs. 3 and 4. On account of its popularity, his own words will be quoted in a description of the operation.

> The upper flap should be figured by a line extending along the side of the bladder surface vertically upwards as far as the measured distance from the root of the penis to the upper margin of the bladder and then carried in a rounded curve across the "linea alba" at this point to join another vertical line of equal length on the opposite side of the bladder. The two groin flaps for superposition are to be made of a rounded lancet-shape, with their roots downwards and inwards at the base of the scrotum and continued along the side of the urethral groove for about half its length.
>
> These flaps should be long enough and detached enough to meet in the median line for their whole length and no sharp angles should be left in their outline. The incision for making them should join that of the lateral border of the first or umbilical flap at about its center. In raising the umbilical flap care must be taken not to make the skin too thin, which is apt to be done in the center of its base near the upper margin of the bladder. At this point there is little or no subcutaneous tissue and the aponeurotic and tense linea alba is thin and easily injured by the knife, consequently the greatest care is required to avoid opening into the peritoneum or subperitoneal fascia.
>
> It is better to lay hold of the flap with the fingers than to use the forceps, which are apt to damage the vitality of the edge of the flaps, on the direct union of which a good deal of the success of the operation depends. In raising the lateral or groin flaps the superficial external pudic vessels are divided, and are often large enough to require ligature.
>
> The upper or umbilical flap should first be dealt with, folded evenly down with its skin surface to the bladder, its corners being stitched with thickish wire sutures to the cut edge at the root of the penis on each side.
>
> The groin flaps should then be placed on the raw surface of the umbilical flap, with their inner edges held in contact along their whole length by six closely-applied wire sutures. The bases of these flaps should pretty closely embrace the root of the penis. The raw surface left by the reflection of the umbilical flap can be easily covered by drawing its edges together with three or four strong and long harelip pins, which have the effect of relieving any strain which may affect the reflected flap. At this stage of the operation the patient's shoulders should be well raised and his knees bent and adducted; to diminish the stretching of the abdominal parietes. The upper borders of the groin-flaps may be held upwards by one or two thick wire sutures, but the site of the groin flaps should be left to heal by granulation.
>
> In the female, the umbilical flap should be large and the incision for the groin flaps on each side should be carried well down, so as to have their roots in great measure connected with the labia. When they are placed together and stitched on the umbilical reversed flap, the vagina should be almost

closed up by them, with but a small opening to allow the passage of the urine. Through this opening a very large india-rubber drainage-tube should be kept in the vagina and be changed and cleaned daily.

As a supplemental procedure in the male, the operation for the epispadias which remains, and for a preputial covering for the penis, will usually be found necessary.

This method, has been modified very extensively, and is, in fact, the principle upon which is based nearly all the flap operations of to-day. Slight variations and improvements have been presented by Michel, Ashhurst, Le Fort, Bigelow, Greig-Smith, Shrady, Mayo Robson, Wheeler, Marsh, Bennett, Richelot, Rickerts, De Forest Willard, and others. Moury, in 1871, utilizes the scrotum and perineum in forming the flap, which he turns upward and attaches to a short abdominal flap—1 inch—by means of a tongue-and-groove suture. The penis is slipped through a small opening in the center of the scrotal flap, thus allowing the urine to pass without coming in contact with the wound. Several cases are reported with a satisfactory result. Gross, in speaking of this method, says that it is the most eligible for males.

A. II. Flap 1*b*.—Thiersch began the operative treatment of exstrophy by curing the epispadias by his own method. The defect in the bladder was then covered with flaps of skin. He cut three skin flaps. An upper penduneulated skin flap, large enough to cover the whole defect, was taken from the middle abdominal region and turned downward, so that the skin surface was directed toward the mucous membrane of the bladder. This flap was sutured to the previously freshened borders of the defect. At the same time, two lateral bridge-shaped skin-flaps with a double pedicle were marked out and dissected up from the subjacent tissue. These two flaps, which are connected at their ends with the surrounding skin, remain, for the time being, in situ. Tinfoil, oiled silk, iodoform gauze, or the like, are inserted beneath them, and they are allowed to granulate. After a time, these granulating skin flaps are detached at one end, laid over the granulating first flap and sutured together in the median line. In this way the anterior wall of the bladder is composed finally of these three flaps of skin. The skinning over of the granulating defects is hastened by means of Thiersch's skin-grafts. Billroth modified Thiersch's method as follows: He covered the defect with lateral granulating flaps only; a lower and an upper skin flap are taken, which at different sittings are laid over the defect with the granulating surface directed inward.

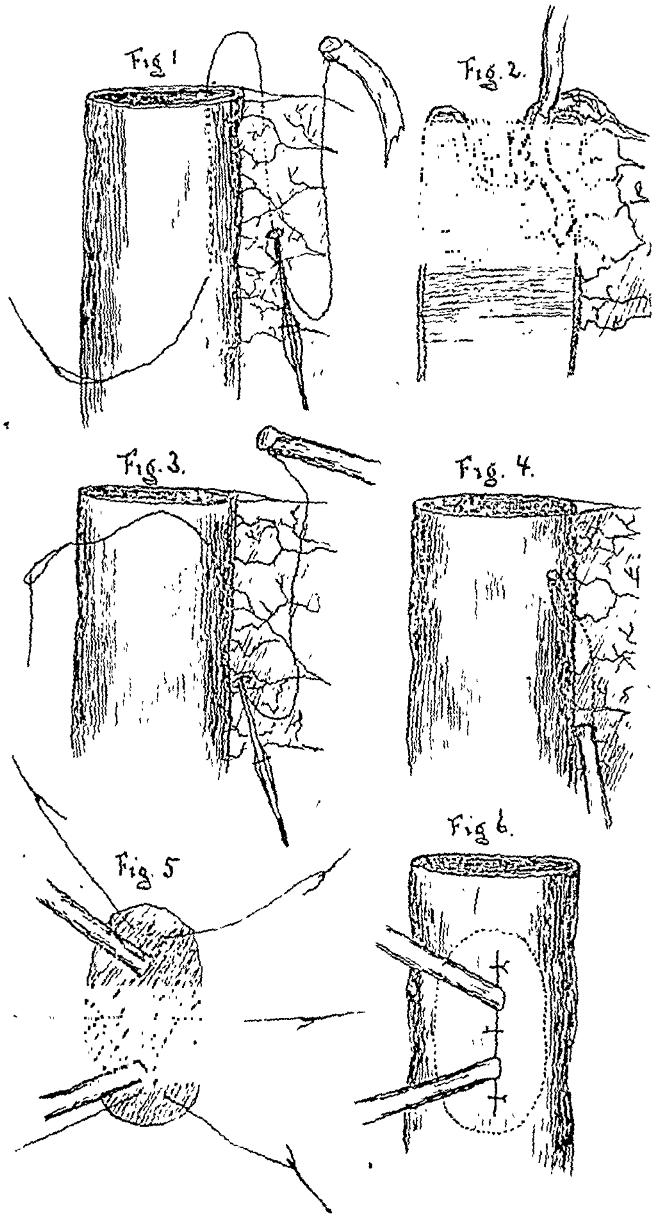
A. II. Flap, 2*a*.—In the reversed flaps one of the most annoying features in the after-treatment was the formation of phosphatic calculi on the hairs which continued to grow on the epidermic surface of the transplanted skin. An effort to exclude this disturbing element was made by Segoud. He dissects up the posterior bladder-wall as far as the entrance of the ureters, and then turns it down so as to make a covering for the groove on the dorsum of the penis. The glans is stuck through the prepuce and the latter is healed on to the bladder flap. The defect resulting from the detachment of the mucous membrane of the bladder is covered with two skin flaps. The urine flows from the ureters into a canal widened above and situated between the groove on the dorsum of the penis and the vesical mucous membrane, which has healed over it. Czerny used the following method: The vesical mucous membrane is dissected up from the periphery toward the center and then united, so as to form a cavity. This cavity is lined throughout with mucous membrane. The skin defects are covered with two lateral bridge flaps.

A. II. Flap, 2*b*.—Rutkowski, in 1899, presented a case in which he used a portion of the intestinal tract instead of skin, or merely mucous membrane, as the material with which to close the defect.' By this method he, too, does away with danger of calculi forming on the hairs. At the same time he repairs a defect in a sero-musculo-mucous viscus by the aid of a sero-musculo-mucous tissue. This is certainly a much more ideal procedure than that where a tissue is employed which is composed of connective tissue, fascia and epidermis, with very little if any contractile muscular tissue or action. His method of procedure is as follows: He resects a loop of small intestine, leaving the resected portion attached to the mesentery. The severed intestine is reunited by an end-to-end enterorrhaphy. The resected loop is divided longitudinally along its convex border, thus giving a broad piece of sero-musculo-mucous tissue—quite similar to the normal bladder which is sutured into the defect of the bladder. One case is reported which left the clinic two months after operation. Upon dogs, he has watched the change in mesentery and mucous membrane. The vessels of the mesentery become gradually obliterated, and the columnar epithelial cells of the intestine in time are replaced by squamous epithelial cells as in normal bladder.

A. II. Flap, 2*c*.—Mundell, in 1899, having met with favorable results in experiments on lower animals, suggests the following method of using normal bladder tissue with which to repair the defect instead of skin, mucous membrane or intestine. "Transplant a portion of bladder wall of, say, a sheep, to the lower lateral abdominal fascia of the patient. After a period of seven or eight days, the union of the two tissues is sufficiently strong to allow a plastic operation whereby a skin flap, with the bladder attached, may be swung over on the exstruded bladder and the edges of the attached piece of bladder sutured to the defective bladder."

A. III. 1.—Wattman made the first plastic operation in 1844 for exstrophy of the bladder. The normal skin was dissected up to a sufficient extent on each side, then pulled forward and sutured in the median line. This case was not encouraging in the result. Necrosis of the flaps took place and was followed by the death of the patient. Gerdy, in 1845, united the bladder in a manner similar to Wattman's procedure, in two cases. The sutures yielded in both, and in one death ensued in five days. In 1849, Langenbeck made a similar operation. After loosening the skin from the posterior wall, it was drawn forward and the edges held in apposition by the aid of "insect-needles." Additional support was given by the application of adhesive plaster. No record was made of the outcome. Wakely, in 1851, suggested drawing the edges over a silver bowl and then suturing in place. The object was to keep back the posterior wall of the bladder, which in many cases pushed forward and so obliterated the cavity. This was never put into effect. Wyman, in 1885, successfully closed the fissure in a case of exstrophy in a child five days old, by the use of hare-lip pins. The patient died two months later of a cause not associated with the condition or the operation.

PLATE IV.



Figs. 1 and 2, experiment No. 11. Figs. 3 and 4, experiment No. 14. Figs. 5 and 6, experiment No. 24.

A. III. 2.—As early as the year 1806, Dubois and Dupuytren proposed to approximate the fissured wall by means of a compression bandage, thereby advancing the application of lateral pressure. This principle has been used quite extensively during recent years by Trendelenburg, Passavant, Neudorfer and others. The osteoplastic method, introduced by Trendelenburg in 1885, has for its object the restoring of the parts to their normal position. By a separation of the sacroiliac synchondrosis he was enabled to bring the rami of the defective pubes into apposition and so form an artificial symphysis. This was followed by suturing the defect in the median line. The separation of the sacroiliac synchondrosis, in children of 3 years, proved to be a very simple and safe operation. To close the defect in the bladder, borders of skin were freshened and held in apposition by means of silver-wire sutures. If primary union does not take place, a secondary operation becomes necessary. König and Küster modified the operation of Trendelenburg, while still retaining the principle. They performed osteotomy on the anterior portion of the pelvic girdle, instead of separating the sacroiliac synchondrosis. Passavant proposed to accomplish the closure of the pelvic bony gap by the application of "brisement force" under the influence of an anesthetic. This suggestion was carried out successfully by Koch. In 1886, Neudorfer relieved the tension and rendered approximation of the margins possible by means of two lateral horseshoe-shaped incisions—the convexity outward—which included all the structures of the abdominal wall to the fascia transversalis. Before suturing the cutaneous margins, the mucous membrane is detached on each side far enough to allow suturing of the same in the median line. Over this the skin is sutured; the os pubis, after its surface has been freshened, is sutured with silver wire. Mikulicz proceeds as follows: Two lateral curved incisions are made 3 to 6 cm. from edge of the vesical mucous membrane and almost parallel to it. This incision penetrates to, but not through, the transversalis fascia or peritoneum. Two lateral bridge flaps containing the entire thickness of the recti muscles are thus formed. The insertions of the recti are freed by removing a small fragment of the pubic bones with them. The entire flap is then dissected up and transplanted toward the median line. The bladder-wall is then dissected free and sutured in the median line, the sutures not involving the mucosa. The flaps are now united in the median line with silver wire. The lateral wounds are allowed to heal by granulation. Escape of urine is provided for by a catheter in the neck of the bladder. As in other flap operations, at subsequent sittings the epispadias is repaired and then the neck of the bladder receives attention. Schlange recommended practically the same, with the exception that the bladder-wall is not dissected free, thus avoiding the danger of sloughing of this portion of wall. Murry reports a successful recovery of a case in which he employed the simple procedure of dissecting free a lateral flap on each side and then uniting these in the median line with the aid of tension and button sutures.

A. IV. 1.—*Mowatt, in 1735, made the first attempt* recorded to relieve the condition of exstrophy. He endeavored to dilate the ureters by closing their orifices with "a small tent and an astringent plaster over it." This procedure caused the child so much discomfort that he was compelled to cease his efforts at treatment, which were, as well, in the line of investigation. In 1842, Chassaignac resorted to dilatation of the ureters. He closed the orifice by inserting a sound in the hope that the dilated ureter would act as a substitute for the bladder. Turbulent symptoms of urine retention were soon evident and his method yielded nothing of value. Breschet, in 1845, tried the above procedure and fever resulted. Gibb, in 1857, also made an unavailing attempt with the same method. Later, in 1861, Bouisson to this end devised a ureter clamp after the manner of a serrefine. But, as in the other cases treated on this line, no satisfactory result was attained.

A. IV. 2.—A plaster bandage was employed by Johannes Buxtorf in 1749. Thinking the protruding mass was a ventral hernia, he attempted to reduce it and maintain the reduction by employing a plaster bandage. The final outcome was the death of the patient.

A. IV. 3.—Catheters in the ureters were used by Pipelot in 1792, who attempted to remove the inconvenience arising from the continual dropping of urine. He retained them in place and allowed them to empty into a receptacle. This device, ingenious enough in itself, did not accomplish the desired result.

A. IV. 4.—A perineal fistula was made by Levis in 1876. He passed a needle, threaded with wire, through the bas fond of the bladder, through the intervening muscular and connective tissue, and out through the skin of the perineum, midway between the scrotum and anus. In this way he established a fistulous communication between the bladder and perineum. The bladder was covered with scrotal flaps and the deep perineal muscles through which the fistula passed were supposed to impart a sphincteric action. Only two cases were recorded, both of which met with an unfavorable termination. One death was due to peritonitis, and the other to an independent cause.

A. IV. 5.—Ureters inserted into the urethra. This ingenious method was introduced by Sonnenberg, with no attempt at a natural receptacle or sphincter. It is merely a method which is not so dangerous as the radical procedures, and as a result it leaves the patient in a condition more suitable for the application of an apparatus. In 1881 this surgeon extirpated the bladder in an extreme case of exstrophy. The entire posterior wall of the bladder was separated from the peritoneum without opening the latter and the resulting defect covered by sliding over a flap *from the side*. The ureters were dissected up from their normal situation and sutured into the dorsal groove of the penis beneath the edges of the skin flap. The patient's condition was so far improved that he could carry a simple urinal. This method has been repeated with a good result by Nehans, and in this country by J. Rilus Eastman.

A. IV. 6.—*Finally, nephrectomy on one side, with lumbar ureteral fistula on the other*, has been recorded by Reginald Harrison, in 1897. The first step was a removal of the left kidney through a lumbar incision. The second step, eleven months later, consisted of an *extraperitoneal implantation of the remaining ureter into the right lumbar incision*; recovery resulted.

Objections: Against all these palliative operations may be placed the fact that, with a few exceptional cases, no sphincter is provided, and a receptacle large enough for practical purposes is not provided.

Apparatus, as a rule, does not fit, and so leakage occurs. If *attached sufficiently tight to prevent leakage*, pressure necrosis is liable to follow. Likewise, considerable attention is required to keep them clean and inoffensive.

Where a flap of skin is used, the urine comes in contact with the wound or raw surface, often causing infection and sloughing. That normal urine is aseptic has been demonstrated conclusively; but, in the majority of these cases, there exists a cystitis of the remaining bladder wall with occasionally a ureteritis or nephritis, in consequence of which the urine is not innocuous. Partial failure is the rule, necessitating one or more subsequent operations. Mikulicz operated on one case nine times, and Billroth on one case nineteen times in twenty-two months. In cases where the epidermis is turned in, phosphatic calculi often form on the hair, and cause much discomfort to the patient. The posterior wall of the bladder is not pushed back to its natural position in the pelvic cavity, and by its protrusion forward the new cavity is reduced considerably in size. The scrotal tissue, which is utilized in some methods, has been proved to be ill-adapted for use as a primary flap.

Where the remaining mucous membrane of the bladder wall is used, the newly formed cavity is usually too small to decrease the troublesome incontinence to any marked extent. This bladder wall, when removed from its surroundings, frequently sloughs from inefficient blood-supply. The utilization of the intestinal wall, after resection, isolation and enterorrhaphy, is certainly a most formidable procedure. Transplantation of the bladder wall from lower animals, thus far, has only been performed experimentally, and needs further investigation. Necrosis of the transplanted flap is to be expected as a result in many such cases.

The coaptation of the edges of the fissure by direct suture is rarely successful. There exists great tension, which often causes sloughing of the flaps, and in addition the same drawbacks that are to be found in other palliative measures. Matas says, in speaking of the results obtained by the various methods accompanied by preliminary steps: "Nor better functionally is the old and original method of Dubois and Dupuytren, resurrected subsequently in a more formidable and dangerous form by Trendelenburg, Passavant and Neudorfer." A tendency to weakening of the pelvic girdle is present. There is no union in front and an artificial lack of solidity occurs behind. In females undue narrowing of the pelvis may result. Treves stated that "In the most successful cases a urinal can not be dispensed with."

Dilatation of the ureters, the plaster bandage, catheters in the ureters, and fistula in perineum are merely of historic value. In cases in which the ureters are inserted into the urethra no attempt is made to form a bladder or sphincter, the aim being merely to facilitate the application of a receptacle. The method of treatment by a nephrectomy on one side and a lumbo-ureteral fistula on the other is very heroic and results in little, if any, improvement of the patient's condition, the effect being a single lumbar urinary fistula instead of a double one in the pubic region. In this case the normal kidney was removed, which is, by the majority of surgeons, considered unjustifiable.

PLATE V.

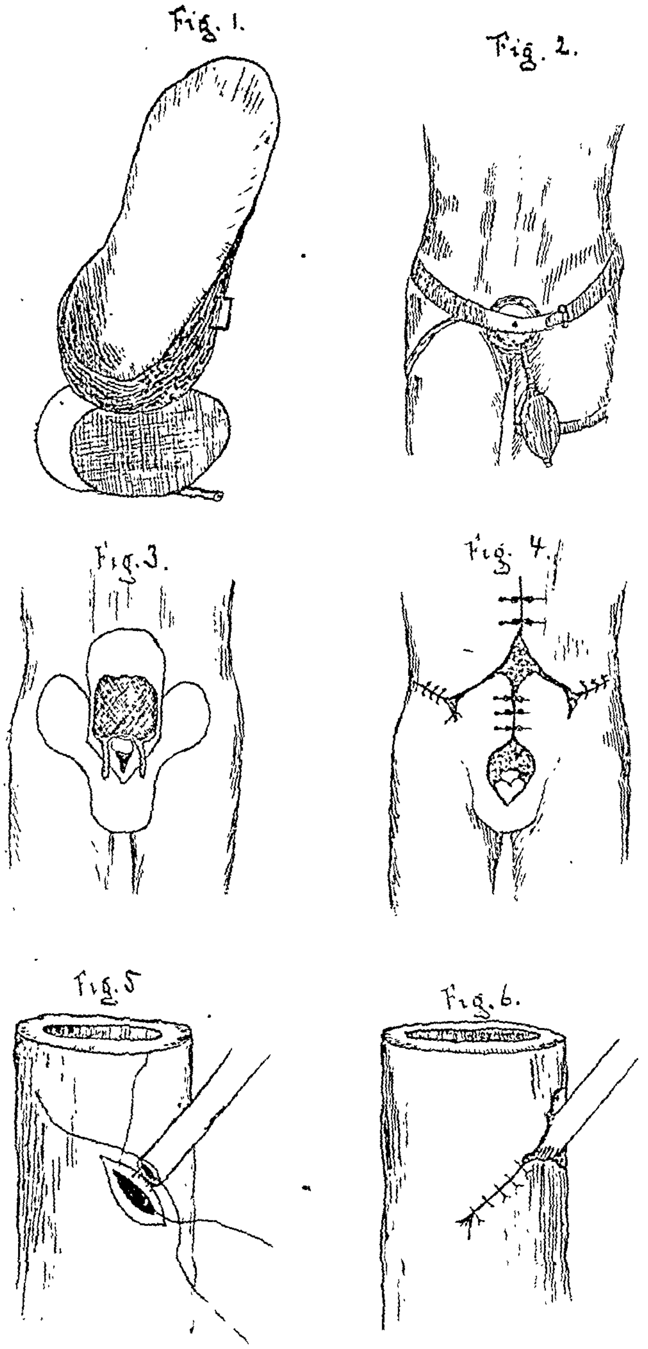


Fig. 1, apparatus worn by Matthew Ussen, 1791. Fig. 2, apparatus recommended at the present time, 1900. Figs. 3 and 4, Wood—flap method. Figs. 5 and 6, Chaput—uretero-intestinal anastomosis.

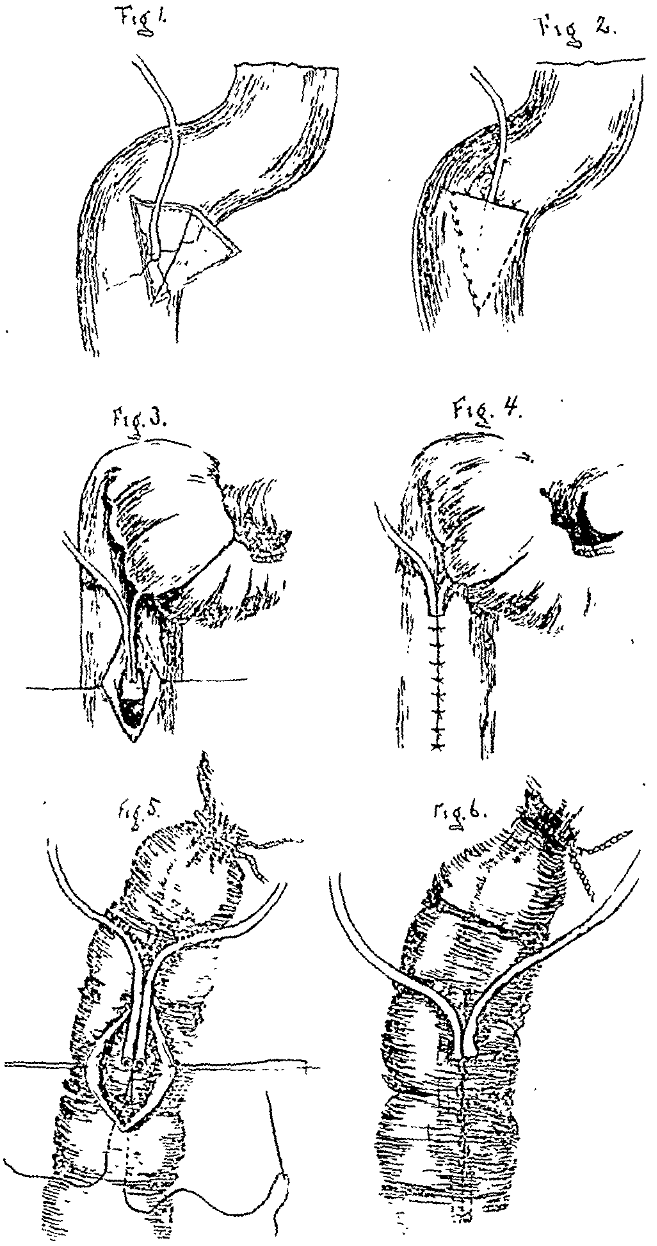
B. I. 1.—The deviation of the urine into the rectum was first suggested by Roux, of Toulon, and performed independently by John Simon, of London, who, in 1851, performed the first ureterorectal anastomosis. As preliminary investigation he experimented on dogs and found that direct implantation of the ureter presented great difficulties to be overcome, and the result was almost always fatal. Profiting by the experience of Mr. Lloyd, he examined specimens in the British Museum in an endeavor to find how low the fold of peritoneum extended. But this could not be satisfactorily determined. He had a catheter made with a stilet of watch-spring ending in a sharp point, in which was an eye for the thread. On July 5, 1851, he passed the catheter up the ureter and succeeded in perforating its coats and those of the rectum, and by means of forceps in the rectum, brought down the thread. The instrument was then removed so as to leave one end of the thread out of the rectum and the other out of the orifice of the ureter. A fresh thread was inserted in the needle and passed at a point about half an inch lower down in the ureter than was the first, so that two ends of the thread protruded from the rectum and two from the ureter. "Now, to obtain a loop bearing on the coats of ureter and rectum, and dependent on a single thread and without a knot, Mr. Simon tied the two anal ends together, and, pulling on the second thread, effected his purpose. The very same succession of measures were taken on the other side. A slight peritonitis and fits of vomiting followed, but recovery from the operation resulted. Three weeks after the operation, only a slight trickling through the aperture of the ureters was taking place, most of the urine passing into the rectum and being expelled with feculent matter. On the thirtieth and the forty-first day the ligatures came away. Four months after operation, as some urine still escaped the natural orifices of the ureters, and as the artificial orifices were demonstrably patent, an attempt was made to close the mouths of the ureters by needles and hare-lip pins, but this did not accomplish the object sought. "Death within a year, with extreme suffering from disease of ureters and kidneys," occurred. This operation was undertaken with two objects, according to Mr. Simon: 1, the establishing of a fistulous passage into the rectum from the ureters, two to three inches above their termination, where in these cases, they course closely against the bowel; 2, the closing of the terminal part of the ureter, so that no urine might be shed on the surface of the abdomen, but that all might pass into the rectum and thence be discharged per anum. The first was completely attained, and the second had been only imperfectly realized. "On post-mortem examination the ureters were found choked up with calculous concretions, which had been the immediate cause of death. The concretions were chiefly phosphatic. It seems probable that the surgical measures employed had excited inflammation along the mucous surface of the ureters, and that with the mucopurulent secretion there had unfortunately been mixed (as occasionally happens in other mucous inflammations) sufficient mortar-like material to make calculi, which, being retained, became an increased and eventually a fatal cause of ureteral and renal irritation. The preparation showed these concretions and also the free fistulous communication between each ureter and the rectum." The operation of Mr. Simon, properly speaking, was not an axial implantation, being a lateral anastomosis instead; but to simplify the classification it has been included under this heading, with this note as explanatory.

In the *Medical Times and Gazette* of 1872, the following is to be found: "Mr. Jones succeeded in making ureters communicate with the rectum and in closing the anterior orifice of left ureter. The actual cautery is now being applied around the margin of the abdominal aperture, so that by contraction the right ureter may be drawn toward a sort of cloaca which exists between the ureters and rectum. In a second case the communication is also completed between the ureters and rectum. Clamp forceps have also been applied to the anterior ends of the ureters after the introduction of the galvano-caustic. These clamps remained a week and then separated. Still no urine escaped in front, so that it was hoped the case was completed. In a few days a little slough separated, allowing urine to escape in front. In this case all urine passed per rectum for twelve days." Thomas Smith, of London, gives the following report:

> In selecting a spot for connecting the ureters with the bowel it seemed that the lumbar region offered the greatest facilities for the operation, since in this situation both the colon and the ureter could be exposed without injury to the peritoneum.
>
> The plan proposed for accomplishing the object in view was the following: To pass a long probe or fine catheter up the ureter from its vesical end as far as the kidney, so as to assist one in recognizing the tube in the cellular tissue of the loins; next, to make the ordinary incisions in the loins as for opening the colon; to find the ureter through the wound, and to pass a temporary ligature beneath it so as to have it at command; next, having withdrawn the probe, to expose the posterior surface of the colon, and dividing the ureter as low down as possible, to insert its upper or renal end through a small incision into the colon and fasten it in position by fine sutures. It was proposed to operate on one ureter at a time and to make the performance of the second operation contingent on the success one might meet with in the first.
>
> Operation, June 19, 1879. The ureter was stitched by means of fine catgut sutures to the back of the colon; a small opening being made in the colon, the end of the ureter was pushed into the bowel, so as to protrude about half an inch into its cavity. A fistula in lumbar wound remained, but closed June, 1879.
>
> August 28, 1880, fourteen months after the operation, the boy being in good health, the second operation was made on the same plan and with the same object, namely, to introduce the right ureter into the back of the colon. He died fifty hours after the operation.
>
> Post-mortem examination, twenty-eight hours after death. The peritoneal surface was quite normal; no trace of inflammation; the lower end of the left ureter was found terminating just above the left common iliac artery. The pelvis of the left kidney was found distended with clear fluid having the appearance of urine; no trace of true renal structure could be found, what remained of the organ being reduced to a fibrous condition spread in a thin layer over the contained fluid.
>
> The portion of ureter attached to the kidney measured 1½ inch in length, and terminated on the back of the descending colon; a probe passed down the ureter could not be made to enter the bowel. The right kidney was much enlarged, being as large as the organ in an adult.
>
> The capsule adhered to the cortical substance, which was very soft and friable and contained many small cysts; the medullary substance was much softer than natural, but contained no cysts.
>
> The pelvis of this kidney and the upper end of the ureter were distended with urinous fluid, and the latter was attached by five sutures to the back of the colon; in the interior of the colon, at its point of attachment to the ureter there was a vascular patch of mucous membrane about the size of a shilling. A small probe could with difficulty be made to pass from the ureter into the cavity of the colon.
>
> It is manifestly one's duty to record the facts of this case for the information of others, since it stands with Mr. Simon's case. I venture to record it as a warning to those who may be tempted like myself, to think that the miseries of ectopia vesicæ can be alleviated by making the ureters discharge their contents into the cavity of the bowel.
>
> Setting aside all difficulties that have to be overcome, and the immediate risks of the operation, it would appear that a permanent and direct communication between the ureter and bowel is of itself a fatal lesion.

These two cases of Simon and Smith, with such unfavorable results, caused the method to wane, and not having met with popularity, it is not again mentioned in the literature until introduced by Gluck and Zeller, in 1881. These surgeons worked experimentally on dogs. Their method was a total extirpation of the bladder, after which the ureters, in some animals, were implanted into the skin, and in others into the rectum. All of the animals in which the intestinal tract was selected for the urinary out-flow died. Novaro, in 1887, made three bilateral implantations on dogs. Two of the animals died, the third lived and was killed thirty days after the operation. Renal infection was reported absent, though no bacteriologic or microscopic examination had been made. Bardenheuer, in 1886, implanted a single ureter in a number of experiments. The animals all recovered from the operation *per se*, but at the necropsy the ureter in each case showed a stricture at the site of implantation, which caused a hydronephrosis. In 1888, Paoli and Buzachi, in four animals, made unilateral implantations. One recovery from operation is reported. Tuffier, in 1888, made experimental implantations into the rectum, but in all cases death resulted from pyonephrosis and general peritonitis. He inserted the ureters so far into the rectum that the ends floated free. R. Harvey Reed, in six cases of bilateral implantation experimentally, met with six deaths, in 1892. In three implantations of a single ureter, one died of peritonitis, one subsequently of ascending infection, and the third resulted in a "perfect cure," no stricture or ascending infection having taken place. This third case was not examined microscopically nor bacteriologically. The method used was as follows: A loop around each ureter, consisting of a double-braided-silk ligature, with ends tied together, and armed with a slightly curved needle. An incision was made about one inch long in the rectum. This loop and needle were inserted into rectum for about an inch in a downward direction, and the needle made to penetrate the wall of rectum and by gentle traction, ureter was pulled into the lumen of the bowel, the aim being to have it from ½ to ¾ inch inserted into the rectum. The rectal wound closed with a continuous suture, which embraced the peritoneum surrounding the ureters and firmly fixed them in the rectum without obstructing the lumen of either ureter. The loops of thread were then put on stretch and cut off close to the peritoneal coat of the bowel. Its elasticity allowed the loops to drop back into lumen of the rectum, while the peristaltic action and the passage of feces would sweep them off the ends of the ureters and carry them out with the stools. There was also incorporated in Dr. Reed's paper the following report: "In the case operated on by Dr. Leet, of Scranton, Pa., where the ureter was implanted into the rectum and the patient recovered from the operation, but died subsequently from an entirely different disease, not connected with the operation, I am told the patient suffered no inconvenience from the ureters being implanted into the rectum. And when a post-mortem was made there was found to be complete union without consequent nephritis. Neither was there stenosis of the ureter." Morestin, in 1892, performed in all sixteen experiments. Ten were bilateral implantations, all of which died, the cause of death being either peritonitis, pyelonephritis or hydronephrosis from stricture. Six were unilateral implantations, three being followed by leakage, and three by stricture. Küster performed, in 1891, on man, a complete cystectomy, followed by implantation of the ureters into the rectum. The patient died on the fifth day after the operation. The post-mortem revealed purulent peritonitis with kidney infection. Chaput experimented on dogs in a great variety of methods, but with almost uniform failure. In 1892, having heard of Reed's successful case on the dog, and considering that the operation could be more easily performed on the human being than on the lower animals, he decided to operate on the human being. For the relief of an uretero-vaginal fistula, he implanted one ureter into the colon. See plate v, Fig. 5 and 6. It is of interest to note that during this operation the iliac vein was opened by mistake, instead of the ureter. The result was called a recovery. Encouraged by the apparently favorable outcome of his first case, he again operated for tuberculosis of the bladder. The left ureter was inserted into the colon on Nov. 25, 1892. Recovery was complete and rapid; the result seemed to be a success. On March 1, 1893, the right ureter was inserted into the colon. Death occurred on the same day. Unfortunately, no autopsy was made. In his procedure the posterior lip of the ureteral orifice is fastened to the still-intact intestine by three or four sutures passed through the muscular layers only. The intestine is then incised for about 1 cm. at a point several centimeters below the preceding row of sutures. The mucous layers of the posterior lips of the two orifices are immediately sutured, and the anterior lips are united by a row of sutures through the muscular wall. The entire end of the ureter should finally be buried at the bottom of a fold of the intestinal wall by means of Lembert stitches so placed that the union will be completely covered for a distance of about 2 centimeters. Rosceszewski, in 1892, made six one-sided implantations, five of which died. Three months after the first operation the remaining living dog was anesthetised and the ureter of the opposite side inserted into the rectum. The animal died of peritonitis. At the autopsy the site of the first inoculation was found to be the seat of a marked stricture, causing a pyonephrosis. Weller Van Hook, in 1893, in his classic contribution to the surgery of the

PLATE VI.



Figs. 1 and 2, Krynski—uretero-intestinal anastomosis. Figs. 3 and 4, Fowler—uretero-intestinal anastomosis. Figs. 5 and 6, Martin—uretero-intestinal anastomosis.

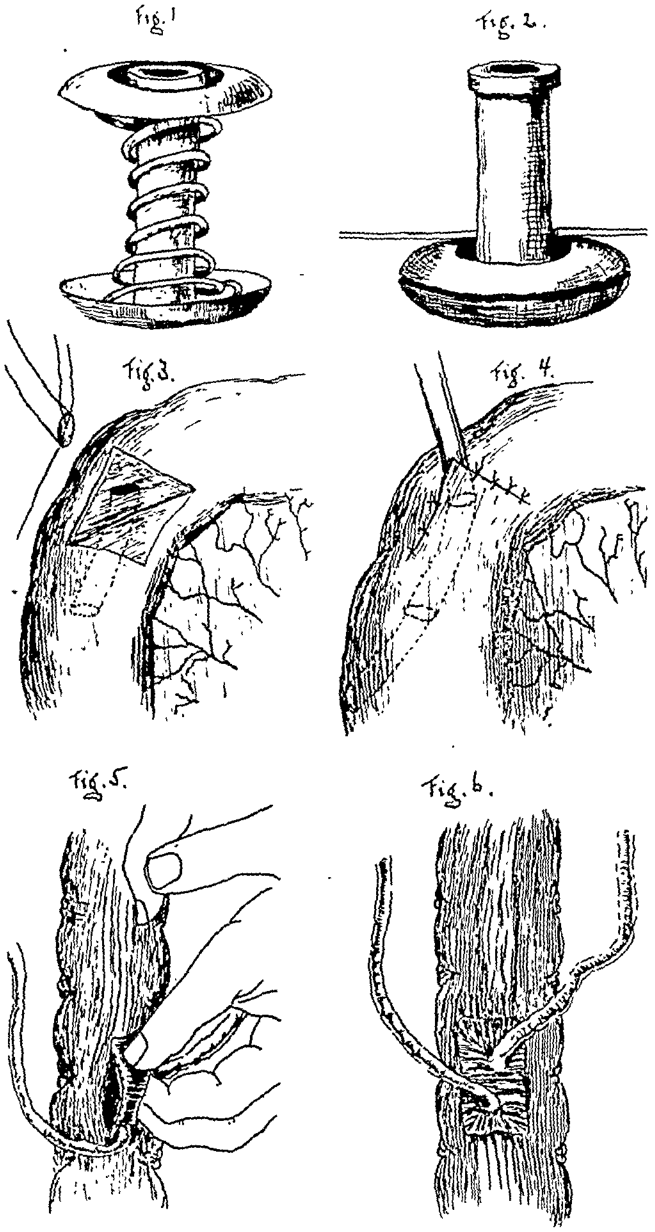
ureters, records some few experiments on the implantation of the ureter into the intestinal tract. After unilateral implantation eight times, five of the animals survived. But following the bilateral operation death occurred in all cases within six days. His method was as follows: After severing the ureter, ligate the cystic end of the duct, and then split the opening of the renal portion of the tube upward for a distance equal to three times its diameter. Cause two small needles armed with a single fine silk or catgut thread to pass from within outward through the split end of the ureter. The ureter is thus grasped in the loop. Now, pass the two needles into the bowel through a small longitudinal slit on the free border and carry them downward about one-half inch. When they are now pushed out through the rectal wall, the ends of the thread may be lightly tied together, drawing the ureter into position and permanently maintaining it there. The operation is completed by covering in the knot with two or more Lembert sutures, closing the rectal wound as well as possible without compressing the ureter, and applying a peritoneal graft. Thompson, in 1893, implanted experimentally into colon and rectum and, in reporting the same, mentions the difficult technic. After implantations into the small intestine, one animal recovered. On necropsy, a moderate hydronephrosis and a slight stenosis of the anastomotic opening was found. He called attention to the peristaltic action, which, by its short duration, but oft-repeated closure of the duct, may act as a causative factor in producing this dilatation. Giordano, in 1894, experimented on fourteen dogs, of which only three lived—77, 84 and 121 days, respectively. He endeavored to improve the results thus far obtained by operating extraperitoneally. Instead of using an anterior abdominal incision, he employed a lumbar, and in some instances even partially resected the sacrum. Duplay, in 1894, operated on a 10-year-old girl, implanting the ureters into the sigmoid, but death resulted. Rein, in 1894, in a case of exstrophy, sutured the ureters into the bowel. The immediate result was satisfactory, but the final result is unknown. Tuffier and Dujarier, in 1896, removed the bladder for carcinoma, after which catheters were fixed in the ureters by means of a stitch that penetrated the wall and its ends were left long. Small openings were now made in the rectum and the ends of catheters, ureters and stitches made to pass through these openings. Catheters and stitches protruded through the anus. Traction on these stitches was relied on to keep up the contact between ureters and rectal wall. The threads were knotted on a forceps and so prevented from retracting. Two months after operation the patient was in good health and able to work. Seven months after operation death occurred. No details were obtainable. Kalabin, in 1898, experimented on twenty-four dogs. On ten he made a bilateral implantation into the rectum, the animals dying in a few days from peritonitis. Fourteen unilateral implantations were made with no better result. In conclusion he states that implantation of both ureters is never admissible, and one ureter is to be attempted only in the most extreme cases. Schnitzler, in 1898, reports two cases of direct implantation, the first for relief of an uretero-vaginal fistula, in which he made an unilateral implantation into the ascending colon, which resulted in recovery. In the second case—carcinoma of uterus—both ureters were implanted, one into the ascending colon and one into the descending colon. In this instance death ensued in a few days, and on post-mortem examination pyelitis was found on one side. C. Beck, Oct. 4, 1899, presented before the Chicago Medical Society a case on which he had operated three months previous. He said at this time there was not the slightest symptom of kidney infection, and gave the following description of his operation: "The operation as performed is a suggestion of Maydl, partly the operation of Dr. Martin, with some modification of my own. The ureters were not implanted in the same line, but one above the other into the sigmoid flexure. The ureters were implanted in such a way that after they had been cut off from the bladder at a distance of an inch the ends of the ureters were dissected, a flap was formed in the gut consisting of peritoneum, subperitoneal tissue and muscular tissue, leaving nothing but the mucosa and submucosa. This flap was turned back and the ureter put underneath it. Underneath the flap a small opening was made and the ureter was drawn about an inch and a half into the bowel, so that the ureter was hanging free, with a portion of it in the bowel. Around this flap the ureter was carefully sutured in a sort of a groove of the wall of the bowel. The peritoneum below was sutured for a short distance." Plate vii, Figs. 3 and 4. Dr. C. Beck lays great stress on the end of the ureter lying free in the lumen of bowel. On account of this fact he expects to prevent infection or stricture. This placing of the free end of the ureter deep into the lumen of bowel was first performed by T. Smith in 1879, and by Tuffier in 1888.

B. I. 2.—Achille Boari, in 1896, presented an ingenious apparatus resembling in many respects the Murphy button, which he had devised with a view to reducing the time consumed in these operations, and also as an aid in securing more perfect union in ureteral implantation. See Plate vii, Figs. 1 and 2. Two successful cases were reported in which the button came away on the eighth and twelfth days, respectively. In neither of these cases had there been any signs of uremia since the operation. Also Chalot, in 1897, advances a mechanical aid, to be used as is the Boari button. It consists of a small tube with olive-pointed ends; a groove or depression, between the bulbous ends, serves to retain the ureter and rectum in contact.

B. II.—Mr. Lloyd, in 1851, attempted to utilize the sphincter ani by establishing a communication between the posterior wall of the bladder and the anterior wall of the rectum. The procedure which Mr.

Lloyd adopted for eventually conducting the urine into the rectum was as follows: He introduced the index finger of his left hand into the anus and glided on that finger a seton-needle armed with a silk thread, to which was attached a thick skein of the same material. There was some difficulty in directing the needle around the pubic ligament from the rectum and close to the prostate into the posterior walls of the bladder, the greatest pains being taken to keep away from the peritoneum; but after a little while the needle was seen to transfix the tumor. The thread was now disengaged from the eye, the lance, which could be taken off from the stem, removed, the handle and stem withdrawn through the anus, and the skein pulled after the thread and made to pass through the protruded vesical walls. Mr. Lloyd considered that the traction exerted downward would cause the urine to pass by the skein into the rectum, and that in all probability a canal might thus be formed which would materially diminish the inconvenience produced by the malformation. The case proceeded pretty favorably up to the fourth day. On the sixth day Mr. Lloyd removed the skein of silk, but the man became much worse and expired on the seventh day after the operation. The body was examined with great care and it was found on opening the abdomen that the immediate cause of death was peritonitis. The rectum had much deviated to the left side of the sacrum and the peritoneum covered it as low down as the anus, so that the seton-needle had passed through the cul-de-sac formed by that membrane so much lower than usual. Thus it became plain how the peritonitis had been excited. Mr. Athol Johnson's case was a repetition of Lloyd's experience. The patient was a child, and death ensued shortly after the operation, from peritonitis. T. Holmes, in 1869, reports a case in which, after performing a flap-operation, he was not satisfied—a sinus persisting—with the result obtained. In an effort to divert the flow of urine into the rectum, he made an artificial communication between the imperfect bladder and the rectum. Profiting by the experience of Mr. Lloyd and of Mr. Johnson, he endeavored to reduce the danger of infecting the peritoneal cavity by using an apparatus similar to Dupuytren's enterotome in making the opening. One blade was placed in the rectum, the other in the bladder, and the two gradually pressed together. In reporting the case Holmes says: "The attempt failed, for though the urine passed in considerable quantities into the bowel, a good part of it still continued to escape above the pubes. I endeavored to obviate this by closing the suprapubic opening altogether by plastic operation. The opening was thus in fact reduced to a sinus. But this caused such intolerable pain when the bladder was distended and such accumulation of sabulous matter in it, that I was fain to abandon the attempt, break open the suprapubic hiatus again and allow the rectal communication to close." Thiersch, in 1881, practically repeated the effort of Mr. Holmes. "In order to avoid the use of a urinal by allowing the urine to flow into the rectum, Thiersch, in the case of a girl, brought about necrosis of the vesicorectal wall by the continuous application of a clamp." J. Frank, in 1899, advises the use of his "bone-coupler," the same as is used for enterorrhaphy, as an aid in establishing a vesicorectal anastomosis.

PLATE VII.



Figs. 1 and 2, Boari-Button, uretero-intestinal anastomosis. Figs. 3 and 4, Carl Beck—uretero-intestinal anastomosis. Figs. 5 and 6, R. Peterson—uretero-intestinal anastomosis.

The operation consists of anastomosing the bladder to the rectum with my decalcified bone-coupler.

The technic is as follows: In a male dog the incision is made in the groin, and in a bitch, in the median line. Generally the bladder is found distended, and is emptied by squeezing it gently with the hand, when the urine escapes through the natural channel. The rectum is next picked up and freed of its contents, as in any intestinal operation. The bladder and the rectum are then brought forward and placed in apposition for anastomosis. Two or three interrupted Lembert sutures are now taken about half an inch below the lower ends of the incisions determined on in the bladder and rectum, care being exercised in selecting them that the coupler, when it is inserted, will not encroach on the ureteral openings in the bladder. A longitudinal incision is then made in the bladder large enough for the coupler selected, and a puckering string applied over and over the cut margin. The rectum is next opened in its long axis and a puckering string similarly applied. The suture should be taken so that the free ends lie uppermost, thus facilitating easy tying. The operator now slips the coupler into the bladder opening, at the same time gently spreading the collars apart, while an assistant makes one knot and draws down on the puckering string until the rubber tubing is felt; another knot is made and the ligature cut off short. The other half of the coupler is then slipped into the rectal opening, and likewise tied and cut off. Several interrupted Lembert sutures are taken around the borders to make the work more secure. The operation is very simple and can be accomplished in ten or fifteen minutes.

He states that of fifteen dogs operated on, ten recovered and five died. This procedure has been performed once on the human subject by A. E. Halstead, of Chicago, the patient living for forty-eight hours, during which time the urine passed per anum with no leakage at site of suture in bladder wall. Death occurred due to shock.

B. III.—Tuffier was the first to propose the implantation of the ureter with its sphincter, its normal orifice, in order to prevent stricture and ascending infection. This is the principle utilized by Maydl in his transplantation of the trigonum. Maydl, in 1894, presents two cases of exstrophy of the bladder which he operated on. It is, in brief, as follows: The bladder-wall is loosened from the abdominal wall; then he opens into the abdominal cavity, at its upper part, and excises from the bladder an oval area containing the ureteral openings. The margin of this area is 1.5 cm. (⅝ inch) away from the orifices. The ureters are carefully dissected out, after having sounds inserted into them. This area, with the ureters attached, is now detached from all surroundings and the remainder of the bladder-wall extirpated. The sigmoid flexure is drawn into the wound and a longitudinal incision made in its convex surface. The isolated area of bladder mucous membrane, with ureteral openings, is now sutured in this incision in two layers, a row of mucous stitches and then the Lembert stitches. The bowel is then replaced in the abdominal cavity and the wound closed with drainage. A permanent drainage-tube is inserted into the rectum. In 1896, he reports three more cases, two of which recovered and one died, the death being attributed to the prolonged narcosis. He reports, in 1899, five more cases, all of which recovered. This method of Maydl, or the principle, that of transplantaing the trigonum, has been repeated quite extensively since its introduction, and has been modified slightly by some operators. Pisani extirpates all of the bladder except the site of the ureteral openings, which is transplanted to the posterior wall of the rectum, through an incision in the anterior wall. The mucous membrane of the posterior wall has been removed for an area equal in size to the surface to be transplanted. He has operated on two dogs; one died at the end of sixty-two hours of collapse, and the second on the sixth day, the post-mortem revealing septic peritonitis. Mauclaire similarly retains the trigone, but the method being so unique in other respects, it has been included under another heading (Artificial Anus). Peterson's method is as follows: "A rectangular flap is formed out of the trigonum, the edges of this flap being made at least one quarter of an inch distant from the ureteral orifices. The sigmoid flexure is drawn downward and incised to a distance equal to the space between the ureteral orifices. This trigonal flap is spread over the incision, so that the orifices open into the incision in the bowel. The external coat of the bladder-flap is united to the bowel by a right-angled continuous suture. The bladder mucosa is pushed inward and the needle passed so that the external bladder wall is inverted and made to rest against the serous coat of the bowel." See Plate vii, Figs. 5 and 6.

The operations based on the plan of Maydl, performed since 1892, are given below, with results:

Date of report.	Operator.	Number of cases.	Recovery.	Death.
1894	Maydl	2	2	
1895	Trendelenburg	1	1	
1896	Maydl	3	2	1
1896	Trombetti	1	1	
1896	Resegotti	1	1	
1896	Krynski	1	1	
1896	Park	1		1
1896	Wölfler	1	1	
1897	Mikulicz	1		1
1897	Ewald	1	1

1899	Maydl	5	5	
		28	25	3

In 1897 Nové Joserand collected seventeen cases, including one by "Tarver," with no reference given. From the available literature, the only "Tarver" writing on this subject appears under the title: "Exstrophy of the Bladder in a Girl of 13 Years; Operation, Relief," in the *Medical Record*, July 10, 1897. This case was not operated on by Maydl's method, nor even a modification of the same. No communication was made with the bowel. Flaps of mucous membrane of the bladder were dissected free and then united, thus forming a small receptacle which held urine for from four to six hours at a time. Of the twenty-eight cases operated on by the Maydl method, or a close imitation of the same, three deaths are recorded, 10.7 per cent. In two cases death was directly attributable to the operation *per se*, 7 per cent. And in this series only one instance is recorded where an ascending infection of the kidney and ureter has taken place, 3.5 per cent. These statistics, as is true of all statistics, must be viewed in the light of a possibility, that additional cases may have been operated on, but having met with an unfavorable outcome, have not been reported. The fact that these cases have lived for a number of years does not of necessity imply that the kidneys in these individuals are not infected. The first case operated on by this method, in 1892, has been lost sight of. The second case, ureters transplanted into sigmoid in 1892, is reported in 1899 as being in perfect health, thus making the duration of the trial extending about seven years. The first case of uretero-rectal anastomosis on record in which the safeguard, the trigonum, was not preserved, lived for nearly one year and then

essentially different from those obtained after operating on man. Kalabin has performed this particular method on five dogs, all of which died in from three to five days. R. Matas undertook to repeat Madyl's typical operation on two dogs, with death following in twenty-four and thirty hours, respectively, from septic peritonitis, evidently caused by infection from the bowel during the operation.

B. IV.—In order to prevent ascending infection, which was found to be so frequent a sequel following implantation into the bowel, other methods were devised with a view to the formation of an artificial valve at the seat of the anastomosis, or in cases where the natural orifices could not be transplanted. The effort was made to make the union with the intestine in such a manner as to imitate the natural oblique course of the ureteral insertion in the normal bladder. Kryinski, in 1896, turns back a triangular flap of rectal tissue composed of serosa and muscularis, and attaches the ureters in this exposed area; then makes a small opening in the submucosa and mucosa for the escape of the urine. The triangular area is then replaced and sutured in position over the ureteral ends. *See Plate vi, Figs. 1 and 2.* Vignoni, in 1896, made a V-shaped valve from the rectal wall; attached the ureters to this flap, and covered all by suturing the wound-edges over the valve. Fowler, in 1898, combined the advantages of a "valve" with those of an oblique insertion of the ureter into the rectum. See Plate vi, Figs. 3 and 4. He makes a longitudinal incision in the bowel down to mucosa, the edges of which he dissects and retracts laterally. Then he cuts a flap in the mucosa, tongue-shaped, with its base up. This flap is folded on itself, with a mucous surface on each side, and fastened in this position with sutures. The ureters are fastened to this flap, and then the flap, with ureters attached, is pushed into the lumen of the rectum, and the wound closed, the mucous membrane first, followed by Lembert stitches which extend considerably above the distal extremity of the ureter. His procedure differs from that of Vignoni in having the ureteral openings in contact with a mucous instead of a fibrous surface, and hence less liability to contracture or *stenosis.* *Franklin H. Martin* reports and exhibits specimens from three animals in which he had transplanted the ureters into the intestinal canal. Specimens were removed in four, eleven and twenty-two months. Two were single and one double, and in each case kidney infection was present. These three cases were the successful results in a series of thirty-four experiments. This demonstration was shortly followed by a presentation of a new method of making the union. See Plate vi, Figs. 5 and 6. This, in brief, consists of the following steps: 1. Dissecting ureters free for a distance of 3 inches; ligate and cut. 2. The ureters are placed side by side and approximated in this position by stitches, which do not enter lumen of ducts. One suture penetrates adjacent walls of both ureters near orifices. This suture is left long and is armed with two needles. 3. A 2-inch long incision is made in upper wall of bowel, penetrating peritoneal and subperitoneal tissue only, and exposing an oval surface of mucosa 2 by 1 inch. 4. Strip bowel of contents and apply clamps; make small incision through remaining coats of bowel at about one-third distance from lower end of denudation. This opening must be large enough to admit the two ureters without pressure. Insert the two needles into lumen of bowel through this opening and bring them out, slightly separated, through the wall at a point about an inch below the opening; that will be a little below the lower border of denuded area. Now pull ureters into where the stay sutures make their exit. 5. Place ureters at right angles to the bowel. Secure them to fibrous and mucous coats of bowel by means of a number of sutures, taking care not to penetrate into mucosa of ureter or to cause a constriction of the tubes. 6. Bury ureters in muscular coat of bowel by folding it over them for a distance of 1 inch and securing it to ureters by fine silk sutures. 7. Peritoneal coat is united over the ureters until they divide, and under them above the point. 8. Close abdomen, with gauze drain. The following "principles of the operation" are presented: 1. The uterers empty into bowel in the direction of its long axis, and urine is discharged in direction of the fecal current. 2. The ureters are buried in the walls of the rectum for an inch or more: the act of defecation will empty the ureter bladder. A longitudinal incision is then made in the bladder large enough for the coupler selected, and a puckering string applied over and over the cut margin. The rectum is next opened in its long axis and a puckering string similarly applied. The suture should be taken so that the free ends lie uppermost, thus facilitating easy tying. The operator now slips the coupler into the bladder opening, at the same time gently spreading the collars apart, while an assistant makes one knot and draws down on the puckering string until the rubber tubing is felt; another knot is made and the ligature cut off short. The other half of the coupler is then slipped into the rectal opening, and likewise tied and cut off. Several interrupted Lembert sutures are taken around the borders to make the work more secure. The operation is very simple and can be accomplished in ten or fifteen minutes.

He states that of fifteen dogs operated on, ten recovered and five died. This procedure has been performed once on the human subject by A. E. Halstead, of Chicago, the patient living for forty-eight hours, during which time the urine passed per anum with no leakage at site of suture in bladder wall. Death occurred due to shock.

B. III.—Tuffier was the first to propose the implantation of the ureter with its sphincter, its normal orifice, in order to prevent stricture and ascending infection. This is the principle utilized by Maydl in his transplantation of the trigonum. Maydl, in 1894, presents two cases of exstrophy of the bladder which he operated on. It is, in brief, as follows: The bladder-wall is loosened from the abdominal wall; then he opens into the abdominal cavity, at its upper part, and excises from the bladder an oval area containing the ureteral openings. The margin of this area is 1.5 cm. (5/8 inch) away from the orifices. The ureters are carefully dissected out, after having sounds inserted into them. This area, with the ureters attached, is now detached from all surroundings and the remainder of the bladder-wall extirpated. The sigmoid flexure is drawn into the wound and a longitudinal incision made in its convex surface. The isolated area of bladder mucous membrane, with ureteral openings, is now sutured in this incision in two layers, a row of mucous stitches and then the Lembert stitches. The bowel is then replaced in the abdominal cavity and the wound closed with drainage. A permanent drainage-tube is inserted into the rectum. In 1896, he reports three more cases, two of which recovered and one died, the death being attributed to the prolonged narcosis. He reports, in 1899, five more cases, all of which recovered. This method of Maydl, or the principle, that of transplantaing the trigonum, has been repeated quite extensively since its introduction, and has been modified slightly by some operators. Pisani extirpates all of the bladder except the site of the ureteral openings, which is transplanted to the posterior wall of the rectum, through an incision in the anterior wall. The mucous membrane of the posterior wall has been removed for an area equal in size to the surface to be transplanted. He has operated on two dogs; one died at the end of sixty-two hours of collapse, and the second on the sixth day, the post-mortem revealing septic peritonitis. Mauclaire similarly retains the trigone, but the method being so unique in other respects, it has been included under another heading (Artificial Anus). Peterson's method is as follows: "A rectangular flap is formed out of the trigonum, the edges of this flap being made at least one quarter of an inch distant from the ureteral orifices. The sigmoid flexure is drawn downward and incised to a distance equal to the space between the ureteral orifices. This trigonal flap is spread over the incision, so that the orifices open into the incision in the bowel. The external coat of the bladder-flap is united to the bowel by a right-angled continuous suture. The bladder mucosa is pushed inward and the needle passed so that the external bladder wall is inverted and made to rest against the serous coat of the bowel." See Plate vii, Figs. 5 and 6.

The operations based on the plan of Maydl, performed since 1892, are given below, with results:

Date of report.	Operator.	Number of cases.	Recovery.	Death.

In 1897 Nové Joserand collected seventeen cases, including *one* by "Tarver," *with no reference given*. From the available literature, the only "Tarver" writing on this subject appears under the title: "Exstrophy of the Bladder in a Girl of 13 Years; Operation, Relief," in the *Medical Record,* July 10, 1897. This case was not operated on by Maydl's method, nor even a modification of the same. No communication was made with the bowel. Flaps of mucous membrane of the bladder were dissected free and then united, thus forming a small receptacle which held urine for from four to six hours at a time. Of the twenty-eight cases operated on by the Maydl method, or a close imitation of the same, three deaths are recorded, 10.7 per cent. In two cases, death was directly attributable to the operation *per se.* 7 per cent. And in this series only one instance is recorded where an ascending infection of the kidney and ureter has taken place, 3.5 per cent. These statistics, as is true of all statistics, must be viewed in the light of a possibility, that additional cases may have been operated on, but having met with an unfavorable outcome, have not been reported. The fact that these cases have lived for a number of years does not of necessity imply that the kidneys in these individuals are not infected. The first case operated on by this method, in 1892, has been lost sight of. The second case, ureters transplanted into sigmoid in 1892, is reported in 1899 as being in perfect health, thus making the duration of the trial extending about seven years. The first case of uretero-rectal anas-

tomosis on record in which the safeguard, the trigonum, was not preserved, lived for nearly one year and then died with infected kidneys. The case of Richardson, in which the urine passed per anum for seventeen years and then finally died "of fever," may be cited again in this connection. Cases of chronic cystitis may live comfortably for years without any symptoms of ascending renal infection; and, more rarely, other cases do acquire a pyelonephritis; the reason for this different behavior of these cases can only be surmised. It is claimed by some that even if infection may occur, the operation is nevertheless a justifiable procedure, because it allows the individual to become a useful member of society, at the same time enabling him to indulge in the customs of his associates as does the normal person. This state of affairs, it is claimed, if even for a short time, is to be preferred to a longer lease of life under circumstances which at best will make it pitiable. That the rectum will tolerate the presence and accumulation of the urine for a variable number of hours has been conclusively demonstrated by this series of operation and others, and also by the experimentation on the lower animals. In only two of the above cases was there incontinence, the others retaining the urine without any difficulty for from three to seven hours, and in one instance as long as ten hours. The Maydl method has not been employed extensively in experimenting on the lower animals; and in the few instances where it has been repeated on dogs the results have been essentially different from those obtained after operating on man. Kalabin has performed this particular method on five dogs, all of which died in from three to five days. R. Matas undertook to repeat Madyl's typical operation on two dogs, with death following in twenty-four and thirty hours, respectively, from septic peritonitis, evidently caused by infection from the bowel during the operation.

B. IV.—*In order to prevent* ascending *infection,* which was found to be so frequent a sequel following implantation into the bowel, other methods were devised with a view to the formation of an artificial valve at the seat of the anastomosis, or in cases where the natural orifices could not be transplanted. The effort was made to make the union with the intestine in such a manner as to imitate the natural oblique course of the ureteral insertion in the normal bladder. Kryinski, in 1896, turns back a triangular flap of rectal tissue composed of serosa and muscularis, and attaches the ureters in this exposed area; then makes a small opening in the submucosa and mucosa for the escape of the urine. The triangular area is then replaced and sutured in position over the ureteral ends. See Plate vi, Figs. 1 and 2. Vignoni, in 1896, made a V-shaped valve from the rectal wall; attached the ureters to this flap, and covered all by suturing the wound-edges over the valve. Fowler, in 1898, combined the advantages of a "valve" with those of an oblique insertion of the ureter into the rectum. See Plate vi, Figs. 3 and 4. He makes a longitudinal incision in the bowel down to mucosa, the edges of which he dissects and retracts laterally. Then he cuts a flap in the mucosa, tongue-shaped, with its base up. This flap is folded on itself, with a mucous surface on each side, and fastened in this position with sutures. The ureters are fastened to this flap, and then the flap, with ureters attached, is pushed into the lumen of the rectum, and the wound closed, the mucous membrane first, followed by Lembert stitches which extend considerably above the distal extremity of the ureter. His procedure differs from that of Vignoni in having the ureteral openings in contact with a mucous instead of a fibrous surface, and hence less liability to contracture or stenosis. Franklin H. Martin reports and exhibits specimens from three animals in which he had transplanted the ureters into the intestinal canal. Specimens were removed in four, eleven and twenty-two months. Two were single and one double, and in each case kidney infection was present. These three cases were the successful results in a series of thirty-four experiments. This demonstration was shortly followed by a presentation of a new method of making the union. See Plate vi, Figs. 5 and 6. This, in brief, consists of the following steps: 1. Dissecting ureters free for a distance of 3 inches; ligate and cut. 2. The ureters are placed side by side and approximated in this position by stitches, which do not enter lumen of ducts. One suture penetrates adjacent walls of both ureters near orifices. This suture is left long and is armed with two needles. 3. A 2-inch long incision is made in upper wall of bowel, penetrating peritoneal and subperitoneal tissue only, and exposing an oval surface of mucosa 2 by 1 inch. 4. Strip bowel of contents and apply clamps; make small incision through remaining coats of bowel at about one-third distance from lower end of denudation. This opening must be large enough to admit the two ureters without pressure. Insert the two needles into lumen of bowel through this opening and bring them out, slightly separated, through the wall at a point about an inch below the opening; that will be a little below the lower border of denuded area. Now pull ureters into where the stay sutures make their exit. 5. Place ureters at right angles to the bowel. Secure them to fibrous and mucous coats of bowel by means of a number of sutures, taking care not to penetrate into mucosa of ureter or to cause a constriction of the tubes. 6. Bury ureters in muscular coat of bowel by folding it over them for a distance of 1 inch and securing it to ureters by fine silk sutures. 7. Peritoneal coat is united over the ureters until they divide, and under them above the point. 8. Close abdomen, with gauze drain. The following "principles of the operation" are presented: 1. The uterers empty into bowel in the direction of its long axis, and urine is discharged in direction of the fecal current. 2. The ureters are buried in the walls of the rectum for an inch or more: the act of defecation will empty the ureter by a milking process. 3. The ureters are protected by muscular coat of intestine. This coat will hold ureters closed when rectum is aiding in defecation. 4. The ureters are implanted in lower bowel, which is normally empty except when defecating. This method was employed upon nine animals, seven of which died and two recovered. One of those which survived the operation was killed after about three months while in apparent good health. On examination one kidney was found to be infected.

B. V. 1.—Rose, Gallet, and Resegotti report the cases which are included under this section. By making a small vagino-rectal fistula, and then closing the anterior vesical wall, with a closing of the vagina, the urine was conducted into the rectum.

B. V. 2.—Mauclaire advised the following procedure: A section of bowel is made at about the junction of the sigmoid and rectum. The distal end of sigmoid is sutured into the inguinal region or perineum as an artificial anus. The trigone, with the ureters, is placed within the proximal end of the rectum, which is then closed. This operation was performed on man by Gersuny.

B. V. *3a.*—Tizzoni and Poggi conducted a series of experiments on dogs in an effort at making an artificial bladder from an isolated loop of intestine. In the first step, a loop of intestine was resected. At a second, the bladder was extirpated and the ureters inserted into one end of the isolated loop of intestine, the other end of which was connected with the urethra. As a result, incontinence was at first present, but normal evacuation soon followed. They also tried to do the entire procedure at one sitting, but met with failure in every instance.

B. V. *3b.*—Hochenegg suggested an artificial bladder, also of a loop of bowel, but communicating with the intestinal canal.

Objections: The liability to ascending infection of the ureter and kidney and stenosis of the opening of the duct, may be advanced as an objectionable point. Matas says: The operator who cuts off both ureters from the bladder and transplants them into the colon, must experience a certain and unavoidable anxiety—an axiety that only further experience will overcome—that is born of the feeling that he has burned his ship behind him and has staked all his patient's chances, all his hopes, in the hazard of the game. It is the utter and absolute hopelessness of remedying the evil when this does occur that must make any conscientious operator vacillate and question his mind and his responsibility many times over before deciding to embark in so perilous an undertaking."

The above-stated weak points will be found to hold especially true of the methods of axial implantation.

In vesico-rectal anastomsis the normal ureteral insertion, as a safeguard, is retained. The method of J. Frank is undoubtedly a marked improvement over the old and forgotten methods of producing anastomosis. Difficulty may be experienced in perfectly closing the anterior wall of the bladder. The operation is only applicable on the male, and it is noted in this connection that but few cases occur in the female. Martin and Taylor, in the "American Text Book of Genito-Urinary Diseases": "In the cases in which the intestine or rectum opens into the bladder, the bowel and contents greatly aggravate the severity of the inflammation and markedly favor ascending infection."

In implantation of the trignonum vesicæ, ascending infection occurs in some cases of cystitis, where the normal insertion of the ureters is not interfered with. 1. Is it not just as liable to occur, if not more so, after this area of bladder-wall is inserted into the rectum? 2. The so-called "muscles of the ureters," which tend to maintain this oblique insertion of the distal ends of the ducts, are separated from their origin and are hence rendered worthless. 3. According to Fowler, the rectum or sigmoid proper is not a closed cavity in the same sense that the bladder is, and accumulating urine can not exercise pressure to the extent that this occurs in the normal urinary viscus. 4. Danger of the implanted trigone to slough. 5. The existence of a congenital anomaly in the sigmoid or omega colon may occur, in which the mesentery is so short that it will be impossible to drag the colon to the median incision, thus seriously complicating the technique, as in Park's case. (Matas.) 6. The possibility of contaminating the peritoneum, in the course of the vesico-colostomy or subsequently, if sloughing should occur after the operation has been completed. (Matas.) Pisani's mode of procedure seems to present no particular advantage. Peterson has in no way decreased the time consumed, nor rendered the danger of kidney infection or peritoneal infection less.

The "valve" or particular manner of inserting the ureters into the wall of intestine, will, in all probability, prevent gross macroscopic contamination, but will be ineffective as a barrier against microscopic infection. The experiments thus far have not been particularly encouraging. Thompson, in speaking of the peristaltic action, considers it not a desirable point, but on the contrary regards the occlusion, short in duration but oft repeated, as a causative factor of hydronephrosis. This in itself is predisposing to infection.

1. In vesico-vagino-rectal fistula there exists the difficulty of establishing a water-tight communication from the ureteral orifices into the rectum. There are also the same objections as to others in this division. Ascending infection is reported in one case (Rosegotti), operated on in this manner. 2. The artificial anus theoretically is a marked improvement on the other methods, as the ureters open into, and the urine is conveyed to, a cavity comparatively sterile. The formation of an efficient sphincter for the bowel is doubtful and the resulting artificial anus would be by some considered but little improvement over the original con-

dition. The operation itself is quite formidable. 3. An artificial bladder opening into the urethra approaches in theory very closely the ideal. The mesentery as a band stretching across the abdominal cavity might be a cause of incarcerations and strangulations of the bowel. But practically the procedure would be a most formidable operation. An artificial bladder opening into the intestinal tract is a similarly dangerous undertaking, and as it communicates with the bowel, the new bladder seems to be of no practical value. The method is open to the same objections cited above.

EXPERIMENTS.

The following experiments were undertaken with a view to determine which of the less complicated methods would prove the most desirable ureteral implantation. The form of the report is a condensed table, or list of the experiments, with the results, and followed by supplementary notes in which details deemed worthy of mention are recorded.

EXPERIMENT 1.—The right ureter was inserted into the rectum by the Van Hook method: the animal made an uneventful recovery.

EXPERIMENT 2.—Both ureters were implanted by the Van Hook method and the animal died on the second day after the operation. At necropsy a diffused peritonitis was manifest, and fluid was found in the peritoneal cavity.

EXPERIMENT 3.—The right ureter was inserted, after the plan advised by R. H. Reed; the animal escaped the next morning.

EXPERIMENT 4.—Both ureters were inserted in the same manner as in No. 3, and the animal died thirty-six hours after the operation. Fluid was found in the peritoneal cavity, with peritonitis.

EXPERIMENT 5.—A bilateral implantation, into the rectum was made according to the plan of Chaput. (See Plate V., Figs. 5 and 6). Death followed on the second day from peritonitis and leakage.

EXPERIMENT 6.—A bilateral implantation was made by the method of Krynski. (See Plate VI., Figs. 1 and 3.) The result was about the same as in No. 5.

EXPERIMENT 7.—Implantation of both ureters was made by means of a "metallic nozzle." This contrivance consisted of a small tube with a bulb at one end, and two silk threads, each tied in the middle to the tube at the base of the bulb, and each end of each thread armed with a small round needle. (See Plate III. Figs. 1 and 2.) The needles were passed from within out through the walls of the ureter, at a reasonable distance from its cut end. Gentle traction on these threads drew the bulb into the ureteral orifice. A small opening was next made into the rectum and the needles passed into the opening and out through the rectal wall. Traction again brought the "tube" and ureteral end into the rectum; the threads were then tied on the outside, and the knot covered by a few Lembert stitches. Death resulted.

EXPERIMENT 8.—In this experiment an effort was made in the direction of an artificial bladder—from an isolated loop of intestine—similar to the method adopted by Tizzoni and Poggi. After making a median incision in the abdominal wall and bringing up a loop of intestine, six to eight inches of the bowel was resected, but retaining its attachment with the mesentery. This isolated loop was thoroughly cleansed by flushing with warm sterile water, then wrapped in warm compresses and laid to one side. The divided intestine was then united by circular enterorrhaphy and replaced in the abdominal cavity. The ureters were then located, ligated and divided; the proximal end was then laid on one end of the isolated loop of intestine and attached thereto by a silk suture, penetrating all coats of each. (See Plate III, Fig. 3.) This end of the loop was then invaginated, carrying with it the open end of the ureter, into the lumen. (See Plate III, Fig. 4.) The invagination was fixed in place by sutures. The other ureter was attached in the same manner to the opposite end of the isolated loop, and the middle of the artificial bladder thus made was sutured in the abdominal wound and then opened. The animal died on the second day from peritonitis.

EXPERIMENT 9.—A second operation was done by implantation of the left ureter, one week after the first operation, by the same method, that of Van Hook. Death resulted on the second day. On post-mortem the right side showed slight dilatation; cocci and bacilli were found in the pelvis: left side was negative. Diffused peritonitis was evident, with leakage.

EXPERIMENT 10.—This case was in all respects like that of No. 8, except that the cut end of the isolated loop was first invaginated, and then the ureters drawn into the lumen by the Van Hook method, and attached to the wall beyond the margin of the invaginated end. (See Plate III., Figs. 5 and 6.) The anchoring stitch was covered by Lembert stitches. The animal lived five days. Necropsy showed a general peritonitis, but no leakage. Both ureteral orifices were patent.

EXPERIMENT 11.—An attempt at this point was made to more effectively guard against leakage and infection by drawing the ureter through the v-shaped, triangular space at mesenteric side of the bowel—which is formed by the non-blending of the peritoneum after it surrounds the bowel. (See Plate III, Fig. 5.) A darning needle with a double thread was attached to the ureter, and at a point about 2.5 cm.—1 inch—from the cut end of the isolated loop of intestine, the needle was inserted into and traversed this v-shaped space to the incised edge, where it was brought out. The thread, at its point of entrance into the mesentery, was then grasped by a slender anatomical forceps. (See Plate IV., Fig. 1.) As traction is applied to the needle and thread, the forceps burrows its way to the margin, thus dilating the track of the needle. The forceps is then withdrawn and the ureter is easily drawn into this "sleeve" and out to an extent of about 1 cm.—½ inch. Then the cut end of the bowel is invaginated up to the point of insertion of the ureter. (See Plate IV., Fig. 2.) The ureter is anchored to the wall of bowel as before mentioned in No. 10. (See Plate III., Fig. 6.) The animal died on the sixth day from peritonitis. Both ureters were patent.

EXPERIMENT 12.—A repetition of No. 11 with death resulting on the third day; peritonitis; both ureters patent.

EXPERIMENT 13.—In all respects similar to Nos. 11 and 12, except that only one ureter—the right—was inserted; the opposite end of isolated gut was included in the abdominal wound. Recovery was the result.

EXPERIMENT 14.—Both ureters. In an attempt to retain the advantages of the "sleeve" and to add those of obliquity in implantation into the intact bowel, a variation from the last procedure was adopted. The darning needle and forceps, as used in No. 11, were again utilized. The needle, armed with the thread which is attached to the ureter, is inserted into the triangular space between bowel wall and mesentery, and is made to travel in this space for a short distance. Then the point penetrates the walls and enters the lumen of the bowel. After proceeding in the lumen of the gut for a distance of about 1 cm.—½ inch.—the needle again penetrates all coats and is brought out on the side of the bowel about .5 to 1 cm.—¼ to ½ inch—above the mesenteric attachment. The thread is grasped by the slender forceps, and by the aid of gentle traction, the forceps bores its way through the coats into the lumen of the bowel; then after slight dilatation of this artificial canal, the forceps is removed and the ureter pulled into the bowel, along the passage thus made. (See Plate IV., Figs. 3 and 4.) Death on the third day.

EXPERIMENT 15.—A repetition of No. 14, except that one ureter—the right—was inserted instead of both, with the result that the animal recovered.

EXPERIMENT 16.—Similar in all details to No. 14. Both ureters were inserted by the so-called "sleeve" method, resulting in death on the fourth day.

EXPERIMENT 17.—The animal in experiment No. 15 had recovered apparently. The right ureter had been implanted by the sleeve method into the ileum, five weeks previously. Now the left ureter was implanted by the same method, with the result that the animal might be said to have recovered from the operation per se. But seeing that ultimate recovery was improbable, the animal was chloroformed nine days after operation. The right kidney was a hydronephrotic sac, enlarged to the size of a bladder fully distended. The right ureter was enormously dilated, with complete stenosis of the orifice. In the lumen of the bowel, the site of insertion of the ureter was almost obliterated in the folds of the mucous membrane. The ileum in the vicinity of the inosculation was decidedly hypertrophied. The left kidney, as also its ureter, was slightly enlarged, dilated and congested; the ureteral orifice was patent but reduced in size. Colon bacilli and cocci were present. There were no colon bacilli in the right kidney; a few cocci were present.

Experiment 18.—Both ureters were implanted by the "sleeve" method described in No. 14. Death occurred on the third day from peritonitis.

Experiment 19.—A repetition of No. 18, resulting in death on the sixth day.

Experiment 20.—Trigone. A typical Maydl method was employed. Death resulted in two days; necropsy revealed a diffused peritonitis.

Experiment 21.—The same as No. 20, with the same result.

Experiment 22.—The "sleeve" method, as in No. 14, was again employed. The right ureter was implanted, with a resulting recovery.

Experiment 23.—The same steps were utilized, as in No. 22, with the same result.

Experiment 24.—Left with trigone. A modification of the Maydl method was employed. An effort was made to reduce the number of stitches used and hence decrease the time consumed, and at the same time to lessen the liability of fecal fistula following, as has occurred in a number of otherwise successful cases on the human being. The following steps were employed in this procedure: 1. Removal of the trigone as in the Maydl method. 2. Bringing of the sigmoid into the abdominal incision. 3. An incision about 4 cm.—1½ inch—in length is made in the sigmoid. 4. The removal of the mucosa, by means of a curved curette, from the intestinal wall for a distance of 1 to 1.5 cm.—¼ to ½ inch—in all directions from the opening. 5. In the trigone three sutures are inserted, each armed with two needles, entering on the mucous surface of trigone. (See Plate IV., Fig. 5.) Two needles placed equally distant from the edge of the trigone and ureters, and one between the ureters. 6. The needles are inserted into the opening in the bowel, and are brought out, one on each side of the incision, near its superior and inferior angle, and one in the middle. 7. The trigone, having been folded in such a manner that its size is reduced to the least possible extent, is inserted into the bowel, through the opening made for it. 8. The six needles are removed and the three sutures tied. 9. The knots are covered by means of a Lembert suture. (See Plate IV., Fig. 6.) This method was put into effect only once, on an animal which had one ureter implanted by the "sleeve" method five weeks previous. The animal died on the second day. Necropsy revealed a diffuse peritonitis, probably due to infection at the time of operation. There was no leakage. The right kidney—first operation—showed a hydronephrosis, a greatly dilated sac, with but a rim of kidney tissue at its convex periphery. The right ureter was dilated to twice its natural size. There was absolute stenosis at site of implantation into the intestine, this point being but barely visible on the mucous surface of bowel. The left kidney was congested, but there was no dilatation of pelvis or ureter.

CONCLUSIONS.

The above table shows that twenty-four experiments were made; of these, one animal escaped, the result of which would in all probability have been a recovery, as it was an unilateral implantation, and the series shows that all unilaterals recovered. Of the remaining twenty-three experiments, five recoveries resulted, and in each instance with stenosis and hydronephrosis; this is practically a removal of one kidney. The result attained in the foregoing series of experiments, was not altogether unexpected.

The literature establishes beyond peradventure, that uretero-rectal implantation has been, and still is, a very unsatisfactory operation. Especially is this true in cases where both ureters are transplanted at the same time. The results obtained in experimentation on the lower animals are most discouraging. Matas, in speaking of Maydl's operation on dogs, considers the operation to be much more simple in the human subject, and less likely to be followed by septic infection. Contamination from the bladder or bowel can be much more effectually guarded against, especially if the sigmoid mesocolon is long enough to permit the bowel to be dragged out of the median incision.

Chaput is quoted as saying: "I believe that the difficulty in obtaining good results in these operations on dogs is due in part to the very small size of the ureter in the animal, and in part to the great rigidity of the intestinal walls causing the suture to cut through the tissues and rendering union almost impossible. The experiments on dogs therefore are not to be relied on to furnish material from which to draw valuable conclusions as to the advisability of similar operations on man."

In every instance where both ureters were transplanted, death followed in from two to six days, being due to peritonitis, with or without leakage.

In each instance where a single ureter was implanted at a first operation, the animals recovered from the operation without any bad symptoms, and passed urine per anum, or through the artificial bladder in the case which recovered after the making of such a bladder.

The animals in which the second ureter was implanted at a second operation, died, in a similar manner to those in which the bilateral implantation was done at one sitting. The cause of this peritonitis is difficult to arrive at.

All ordinary precautions were taken against infecting the peritoneal cavity. The same steps were pursued in the preparatory technic, in the same room, and with the same instruments, which were found to be absolutely safe by the same operator in performing intestinal work.

Again, the dogs in which one ureter was transplanted recovered without any signs of peritonitis, but when two ureters were made to communicate with the rectum by the same method and under exactly similar circumstances, the operation was followed by this inflammation of the peritoneum and death.

On necropsy, it was found that in all cases of unilateral implantation, stricture and hydronephrosis resulted. The fluid in the sac was never purulent, but on making cultures of this fluid cocci were found, with a few colon bacilli. In the other cases, when the postmortem was performed within a reasonable time after death, cultures were made, and in each instance both bacilli and cocci were found to be present.

The ureter was implanted into both the large and small bowel, with apparently no difference in result. Unfortunately, the animals did not survive the operation for a sufficient length of time to allow that conclusions of material value be arrived at.

But from the above experiments, there can at least be deduced the conclusion, as confirmatory of others, that the bilateral axial implantation of the ureters into the rectum is at best a dangerous procedure.

Further experiments with the implantation of the trigone will be carried on and reported in the future.

TYPHOID BACILLI IN THE URINE.

Not a few of the results of investigations that are made in the laboratory and at the bedside are of comparatively trifling value from the point of view of immediate results of a practical nature. From the standpoint of pure science, however, they may be worth much, and indirectly may lead to definite application in the ultimate aim of medicine, the prevention and cure of disease. In truth, much of our knowledge that is applied in the daily routine of medicine and surgery was obtained as the result of research undertaken with no thought or other incentive than the purely scientific one of discovering truth for truth's sake.

In the case of other facts that are announced as the result of scientific research, their applied working value is at once apparent, and they change not only existing theories but practice as well. Thus the discovery that typhoid bacilli are often present in the urine of patients ill with, or convalescing from, typhoid fever will be productive of great results.

The presence of typhoid bacilli in the urine of a patient ill with enteric fever is important, not only to the patient and his friends, but to the entire community in which he lives. It is important to the patient because it may mean a cystitis, a pyelitis, a prolonged convalescence or an imperfect restoration to health. Occurring as it does, in about 25 per cent. of cases, it should be carefully sought for by the physician, and every typhoid urine that is even slightly turbid, or that is voided with evidence of slight pain or local irritation, should be examined for bacilli. But this is not enough, for in many of these cases no evidence of the presence of bacilli is given by turbidity of the urine or disturbed act of micturition. In fact, subjective complaint is the exception. Typhoid cystitis, as shown by Curschmann, is relatively rare. The only safe way, therefore, is to examine the urine of every case, not forgetting that the organisms are often late in making their appearance and are seldom found before the third week. Their early detection and the proper treatment may save the patient from annoyance, and perhaps from something more serious, such as renal or vesical calculi, for the typhoid bacillus may, perhaps, play a rôle here as it does in the production of biliary calculi.

It is important to detect these cases, because of the great danger of spreading the disease by means of careless disposal of contaminated urine. Neufeld[1] has recently presented this aspect of the case with unusual force, and he contends that the danger from infected urine is greater than from feces similarly contaminated. This arises in part because a given quantity of urine will contain as a rule a larger number of typhoid germs than will a similar quantity of feces. In one of Neufeld's cases he estimated the bacilli at one hundred millions per cubic centimeter. But another reason is that an article of clothing, a sheet, a bed-pan, a urinal, the hands or genitalia may be soiled with urine and the accident much more readily escape notice than a similar mishap with fecal matter, thus increasing the danger of spread of the disease to those caring for the patient. From the point of view of public health the danger from improper disposal of typhoid urine is great. Water fouled with fecal matter will give evidence to sight or smell more quickly than if the contaminating substance is the nearly colorless and less malodorous urine. Urine is more apt to be carelessly thrown out than are feces; a patient recovered from typhoid, especially if he be in the country, is more likely to carelessly urinate than to defecate near a spring, well, brook, stream or pond, and thus to infect the drinking water. And the bacilli remain for a much longer time in the bladder and, therefore, in the urine than in the intestine and the feces. In Gwyn's case[2] they were found in urine voided five years after the attack of typhoid. There seems to be a constant inoculation and reinoculation of the urine as it comes from the kidney, by the organisms present in the bladder, so that the culture-medium being constantly supplied, the growth is repeatedly transplanted and is slow to die out. Thus a patient, months or years after his attack of fever, may unwittingly infect a supply of drinking water and start an epidemic of the disease.

In the management of these cases urotropin has been found to be very efficacious. Given in doses of about 30 grains a day, it causes the turbid urine rapidly to become clear and sterile. Occasionally relapses have been noted. If the bacteriuria is due to some other organism than the Eberth bacillus, the effect of the drug is not so certain.

THE TREATMENT OF EPILEPSY WITH OPIUM AND BROMID.

The essential nature and the intimate pathology of epilepsy are as yet not understood, and we are still without a specific or invariably successful method of treatment. In fact, all of the remedial measures at our command can be said to be only palliative, as even when the attacks have remained in abeyance for long periods of time, definite assurances of cure can not be given. In all cases distinct good can be accomplished by a careful regulation of the diet and the mode of life, and among drugs there is none, intelligently used, that seems so efficient as the bromids. The latter, however, by no means always bring about the desired result, and even when they lessen the number and the severity of the attacks, their use is not wholly unattended with unpleasant effects, and their influence may after a time be lost. Inasmuch as physiologic, as well as pathologic, activity, like all other forms of force, is expended along lines of least resistance, one is at times justified in taking radical steps for the purpose of breaking up what may be designated as the convulsive habit.

[2] Johns Hopkins Hospital Bulletin, June, 1899.

Within recent years a combination of opium and bromid, with various accessories, has been proposed in the treatment of epilepsy, but there has been some want of agreement as to the results obtained therewith. Meyer and Wickel[1] report a small series of cases thus treated, in which the severity of the attacks was mitigated, and both the physical and mental condition was improved. The underlying principle of the plan pursued consists in a gradual increase in the dose of opium, but not beyond 14 grains daily; in careful regulation of the diet; and in applications of cold water. Whether the patient has previously taken bromid or not, the treatment is begun with doses of 3/4 gr. of powdered opium thrice daily. This dose is increased 1/6 gr. on the third day, an additional 1/6 gr. on the fifth, and so on until, on the fifty-first day, the daily dose will be 14 grains. This maximum dose is given for but one day, being replaced on the following days by a mixture of bromids—potassium bromid, 15 gr.; ammonium bromid and sodium bromid, each 7½ grains—in doses of 30 grains thrice daily for two days; then 35 grains for two days, 40 grains for two days, and thereafter 45 grains thrice daily.

From the beginning a dilute solution of hydrochloric acid—1.5 to 200—is given thrice daily after meals in doses of a tablespoonful. In the diet, alcohol, coffee, tea, bouillon, sausage, acids, and strongly spiced articles, mustard, pepper, vinegar, and all spices are forbidden, and salt is restricted to a minimum. Meat is permitted in small amount, and the patient is encouraged to take demulcent soups, eggs, rice, etc., and if constipation be present, fresh vegetables. The diet must be regulated somewhat by the surroundings and the circumstances of the patient. During the first period of bromid administration, cocoa, eggs, and scraped meat, may be added.

From the first day of the period of opium administration a cool bath is taken in the evening before eating, at first at a temperature of 86 degrees for ten minutes, and reducing the temperature 2.25 degrees, and the duration of the bath one minute daily until a temperature of 70 and a duration of three minutes are reached. The baths are thus continued for a week, then, with the same temperature, but for four minutes, for another week; next at the same temperature for five or six minutes. In the first week of the period of bromid administration the bathing is intermitted, then being resumed at 86 for ten minutes and following the course already laid down. Every third day the patient is weighed, and pulse, temperature and respiration carefully observed. The bowels must be kept regular by means of enemata, infusions, abdominal massage, but not purgatives; besides note is taken of the number of attacks and of other details of the patient's condition.

The most important contraindications for the treatment are serious impairment of the nutrition and weakness of the heart. The number of attacks is not diminished during the period of opium administration; it may even be increased. Subsequently, however, the attacks become less frequent, and during the period of bromid administration they cease altogether. The mental state also exhibits distinct improvement. The treatment is to be continued by the administration of large doses of bromid—if possible 2 drams daily—for at least a year, with a tablespoonful of the solution of hydrochloric acid—1.5 to 200—thrice daily, and the same diet as was used during the period of opium administration, avoiding especially alcohol, tea, coffee, spices and meat beyond moderation. A quiet mode of life and avoidance of physical and mental excess, especially excitement, are further conducive to the success of the treatment.
